TURNER AND NEWALL RESEARCH FELLOWSHIP IN ENGINEERING, INORGANIC CHEMISTRY OR PHYSICS or other allied science—The Registrar, The University, Leeds 2 (April 21).

ASSISTANT LECTURER (with an honours degree in mathematics) in MATHEMATICS—The Secretary, Bedford College, Regent's Park, London, N.W.1 (April 23).

ANALYST, Assistant Experimental Officer grade or Experimental Officer grade, in the Insecticides and Fungicides Section at Long Ashton Research Station, for work concerned mainly with the development and application of methods for the determination of insecticide and fungicide deposits on plants—The Secretary, Research Station, Long Ashton, Bristol (April 24).

CHAIR OF PHYSIOLOGY in the University College, Ibadan—The Secretary, Senate Committee for Higher Education in the Colonies, Senate House, London, W.C.1 (April 24).

LECTURER (with a good honours degree in biochemistry, agricultural chemistry or chemistry, and with postgraduate research experience in biochemistry) in AGRICULTURAL BIOCHEMISTRY, A LECTURER IN SURVEYING AND FORMER ENGINEERING in the Department of Forestry, and an ASSISTANT LECTURER (with special qualifications in applied mathematics) in MATHEMATICS—The Secretary and Registrar, University College of North Wales, Bangor (April 26).

LECTURER (with special qualifications in mechanical engineering) in ENGINEERING—The Registrar, The University, Manchester 13 (April 26).

LECTURERS (3) or ASSISTANTS (3) IN GEOLOGY—The Secretary of University Court, The University, Glasgow (April 30).

CHAIR OF CHEMICAL PATHOLOGY tenable at St. Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 3).

LECTURER (Grade II) or ASSISTANT LECTURER (Grade III) IN THE DEPARTMENT OF THEORETICAL MECHANICS—The Registrar, The University, Bristol (May 7).

LECTURER IN MINING—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (May 8).

READER IN EXPERIMENTAL PHYSICS at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 10).

RESEARCH ASSISTANT IN THE DEPARTMENT OF MINING—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (May 23).

ANGLO-IRANIAN OIL CO. STUDENT (with good degree, and preferably research experience) in the CHEMISTRY DEPARTMENT, for study of kinetics of gaseous reactions—The Registrar, Imperial College of Science and Technology, London, S.W.7 (May 24).

CHAIR OF PURE MATHEMATICS—The Registrar, The University, Birmingham (May 31).

LECTURER (with a university degree, preferably in forestry, and practical experience of forestry in Great Britain or abroad) in FORESTRY—The Secretary, The University, Edinburgh (June 15).

ASSISTANT LECTURER IN GEOGRAPHY—The Secretary, University College, Bristol.

CHEMIST (with an honours degree in chemistry, metallurgy or chemical engineering, or equivalent qualifications) at the Ministry of Supply, Woolwich, to take charge of electro-deposition unit on pilot plant scale—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.170/544.

CHEMIST or BIOCHEMIST (preferably with a knowledge of the chemistry of either fats, proteins or starch, and/or modern laboratory techniques) for fundamental research work—The Director of Research, Baking Industries Research Station, Chorleywood, Herts.

HEAD (with a degree in science or engineering, and some research experience, and preferably with a knowledge of the iron and steel industry) of THE BRITISH IRON AND STEEL RESEARCH ASSOCIATION'S NORTH EAST COAST LABORATORIES at Northumbria, near Middlesbrough, to lead a team of some twenty scientists and technicians operating on problems in connexion with iron-making and iron-making processes—The Personnel Officer, B.I.S.R.A., 11 Park Lane, London, W.1, quoting "Normanby".

LECTURER (with a university degree in agriculture, and preferably with a knowledge of tropical agriculture, and some teaching experience) in AGRICULTURE, at the College of Agriculture, Mauritius—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODH63/52/06.

PHYSICISTS and ENGINEERS (with at least H.S.C. (science) or equivalent) in THE GUIDED WEAPONS DEPARTMENT, Royal Aircraft Establishment, Farnborough, Hants, to assist in development, testing and maintenance of kinetheodolites, special oscillograph cameras, and other associated equipment in target aircraft—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.65/544.

RESEARCH STATISTICIANS (with a good honours degree in mathematics (including statistics), and preferably with research experience in statistics) in the Department of Statistics, for work concerned with the development of statistical theory and its application to agricultural and general biological problems—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

RESEARCH STUDENT (with a good physics degree and some experience of electronics) to work on a special project which will provide opportunity for study for a higher degree—The Professor of Electronics, The University, Southampton.

SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree in chemistry, or an equivalent qualification, and at least three years postgraduate research experience, and a knowledge of plastics, paints, adhesives, rubbers and/or surface chemistry) to assist in the control of a chemical development section covering miscellaneous research problems in the organic chemistry field—The Administrative Officer, Recruitment, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 40/W.G.M./2.

QUALIFIED CHEMICAL ENGINEER WITH commercial outlook required by progressive firm established consulting and contracting engineers to the petroleum and chemical industries. Require a man of energy and enterprise who had considerable theoretical and practical experience in the field of process plant and equipment. The ability and desire to negotiate contracts at all levels is essential, and applicants must be prepared to travel.—Applications, which will be treated in confidence, should be made in writing to Head Wraggston Processes, Ltd., 24-26 Abchurch Lane, London, E.C.4.

NORMALAIR, LTD., REQUIRE THE SERVICES of a Chemical Engineer, for work in connection with oxygen breathing apparatus and high tide survival equipment. Qualifications to first standard are required, with a good background of inorganic chemistry, whilst some knowledge of rubber and plastic technology would be an advantage.—Applications should be addressed in the first instance to the Chief Engineer, Normalair, Ltd., Yeovil, Somerset.

MULLARD RESEARCH LABORATORIES Surrey have a number of vacancies for Physicists and Electronic Engineers, with a good degree, or equivalent qualification, for work on a variety of projects, including: (1) solid physics; (2) semi-conductors; (3) magnetic materials and devices; (4) microwave techniques and paramagnetic accelerators; (5) advanced electronic circuit designs, including transistor applications; (6) laser television; (7) computers and servo-mechanisms. Some experience in one or more of these fields is desirable, but recent graduates are also invited to apply. Mathematics graduates with experimental leanings are not excluded. Successful applicants will join teams engaged on research and advanced development projects. Location of original work wherever possible is encouraged. Salaries are based on qualifications, experience and age, and are in keeping with present-day levels. General prospects within the organization are excellent.—Apply to Personnel Officer, Mullard Research Laboratories, 100 Oak Lane, Salford, near Redhill, Surrey. Tel. reference B.R.L.

VACANCIES EXIST FOR ONE OR MORE job positions in the Research and Development Laboratory of a well known Company manufacturing abrasive and refractory products. Applicants should have a good science degree, or equivalent qualification, and preferably some industrial research experience in one or more of the following or related fields: ceramics, plastics, paper, textiles, adhesives. Commensurate salary will be on a liberal scale commensurate with qualifications and experience. Prospects for advancement will depend on efficiency and ability to assume responsible leadership. Applications, which should include full details of training, qualifications and experience, will be treated in strict confidence. Location is in the North-West—Box 875, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

CHEMIST REQUIRED, FOR RESEARCH development work in inorganic and physical chemistry. Starting salary up to £750, according to experience and qualifications.—Write for application form to Soudes Place Research Institute, Dorking.

DRUGGILL'S CO (BIOCHEMICALS), LTD., has a vacancy for a Junior Physiologist, for work in laboratories engaged in the testing of broilers. Applicants, preferably female, should have a degree in appropriate subjects. Previous experience with laboratory animals would be an advantage. Salary will be in accordance with level and experience.—Apply in writing to the Secretary, The Druggill's Co. (Biochemicals), Ltd., 100 Road, Speke, Liverpool, 19.

THE STAVELEY IRON & CHEMICAL Company, Limited, invite young graduates in chemistry, who have completed their military service, to apply for a post in the Research Department. The successful applicant will be given the opportunity to familiarize himself with the chemical activities of the company whilst being employed initially upon selected projects connected with heavy chemicals.—Applications should be made in writing to the Research Manager, Staveley Iron & Chemical Co., Ltd., Hollingwood, near Chesterfield.

MIDLAND SILICONES, LTD., AN ASSOCIATED company of Albright & Wilson, Ltd., have a vacancy for an Electrical Development Engineer in their Technical Service Laboratory at Barry, Glam. The duties will involve the development of silicone insulating materials under laboratory and pilot conditions, and their applications in the electrical industry. Candidates should have practical experience of commercial electrical insulating materials, and have some knowledge of physics and chemistry. A non-contributory pension scheme is in operation. Commencing salary according to age, qualifications and experience.—Candidates, aged 28 to 40, and possessing the above qualifications, should apply to the Appointments Officer, Albright & Wilson, Ltd., Oldbury, Birmingham.

LABORATORY TECHNICIAN (MALE, 20 or over) for Medical Centre, Family Planning Association, 64, Skone Street, S.W.1. Work concerns sub-fertility. Experience not necessary. Inter.B.Sc. or G.C.E. (A) desirable. 35-hour week.—Apply in writing to General Secretary.

PETROLEUM ENGINEERS AND PHYSICISTS. Vacancies exist with large oil company for experienced graduates and for those graduating this year to whom training will be provided, for Middle East duty in petroleum engineering. Candidates should have performed National Service and married men must be prepared for initial separation. Substantial allowances in addition to salary. Pension fund. Paid home leave with passages.—Write, quoting No 444, to Box No 7554, c/o Charles Barker and Sons Ltd., 31, Budge Row, London, E.C.4

APPOINTMENTS WANTED

SPECIALISTS (10-15 YEARS' PROFESSOR- experience) seeking chairs in universities for one year or more for founding of scientific connections. Geophysicist (30 publications), geophysics and others. Crystallographer (10 publications), crystallography, 20 others. Mathematician (15 publications), theory of probability, 25 applied mathematics. Specialist—Theoretical Mechanics (40 publications). Send propositions to manager—Box 869, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1

CHEMIST, 26, B.Sc. (FIRST), PH.D., SEVEN years varied research experience, including two in U.S.A., seeks the impossible, fundamental research with adequate remuneration in congenial surroundings. Available November.—Box 892, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

GRANTS & SCHOLARSHIPS

UNIVERSITY OF GLASGOW
COATS FELLOWSHIP IN CHEMISTRY OR PHYSICS
(FOUNDED IN 1948 BY MESSRS J. P. COATS, LIMITED)

Applications are invited for the above Fellowship, which is of the annual value of £300 and is tenable for two years. Candidates should be graduates in science of at least one year's standing of a British university. The successful applicant will be required to undertake research in chemistry or physics (excluding nuclear physics) in the University of Glasgow. Appointment will date from October 1, 1954.

Applications should be lodged with the Clerk of Senate, The University, Glasgow, W.2, not later than May 31, 1954.

WEIZMANN INSTITUTE OF SCIENCE

REHOVOTH, ISRAEL

CHAIM WEIZMANN FELLOWSHIPS

Applications are invited for the above Fellowships, tenable for one year at the Weizmann Institute of Science. The work of the Institute is mainly devoted to fundamental research in the exact sciences. The total stipend is \$5,000 (U.S.), but, for Fellows travelling with their families, an additional grant of up to \$1,000 (U.S.) may be made towards the extra expenses.

Further particulars, details of current work at the Weizmann Institute of Science, and application forms for Fellowships may be obtained from the undersigned. Applications for Fellowships for the academic year 1954-5 should be submitted by not later than May 1, 1954.

J. GILLIS,

Academic Secretary.

UNIVERSITY OF SHEFFIELD

Elton Research Fellowships (three) of at least £260 per annum, with remission of fees for research in chemistry or physics. Tenable for three years from October 1, 1954. Open to graduates of British universities.

Full particulars can be obtained from the undersigned, to whom applications should be sent not later than June 12, 1954.

A Research Scholarship of £350 per annum for research work connected with the chemistry of amino acids, peptides and proteins. Tenable from October, 1954, and renewable, subject to satisfactory progress, up to a period of three years.

Applications, giving full particulars of qualifications, and the names of two referees, must be made to the undersigned not later than June 1, 1954.

A. W. CHAPMAN,
Registrar

HUDDERSFIELD TECHNICAL COLLEGE

RESEARCH SCHOLARSHIPS

Applications are invited from graduates or candidates with equivalent qualifications for Research Scholarships, tenable for two years or more. The Scholarships vary in value from £60 to £300 per annum, and are tenable in the Department of Chemistry, Colour Chemistry and Dyeing and/or other Departments of the College. The Scholarships are open to candidates of either sex.

Further particulars and application forms may be obtained from the Principal, Technical College, Queen Street South, Huddersfield.

H. GRAY,

Chief Education Officer

UNIVERSITY OF SOUTHAMPTON

ESSO RESEARCH STUDENTSHIP

Applications are invited from men with a good university degree, with chemistry as principal subject, for a Research Studentship in chemistry, endowed by the Esso Petroleum Co., Ltd., at £350 per annum, to commence October 1, 1954.

Candidates should apply to the Professor of Chemistry, from whom further particulars can be obtained, before May 15, 1954.

FOR SALE AND WANTED

"JOURNAL OF POLYMER SCIENCE," Vols 1 to 5 (1946-51), £20. "Chemical Abstracts," Vols 11 to 16 (1917-22), £18. "Beilstein," Organische Chemie Band 28, erster und zweiter Teil. FLUORITE OBJECTIVES

× 50 (1/7 in.) Oil Immersion N.A. 0.95

× 100 (1/12 in.) Oil Immersion N.A. 1.30

These new computations of outstanding merit are designed to be used with the NON-DRYING OIL supplied by us.

Compensating eyepieces × 6 and × 8 are available and should be employed to exploit fully the capabilities of these fine lenses.

Each objective is tested on the BAKER OBJECTIVE TESTING INTERFEROMETER and only the finest selected material is used in manufacture.

PIRANI and IONISATION GAUGE FOR RESEARCH AND INDUSTRY

"CATHODEON" COMBINED PIRANI AND IONISATION GAUGE. A compact, self-contained, mains-operated unit for measuring pressure over the very wide range of 1 mm. to 10^{-6} mm., or less of mercury. A Pirani gauge is used over the range of 1 mm. to 10^{-3} mm. Below 10^{-3} mm. a selector switch brings in an ionisation gauge indicating down to 10^{-6} mm. or less. Occluded gases in this gauge may be removed by a built-in "Bombard" feature. Indicator lamps show whether the instrument is set to "Pirani," "Ionisation," or "Bombard." Complete with Pirani and Ionisation gauge heads which are normally supplied in hard or soft glass of 12 mm. bore, but are available in special glasses, bores or connectors to suit customers' requirements. Descriptive leaflet available on request.

SPECIAL FEATURES

- ★ Robust Probe Filaments
- ★ Simplified Controls
- ★ Range extension readily available.

TWO SHILLINGS

THE *Newton*

LONG WORKING DISTANCE ATTACHMENT

... provides a working distance of 12.8 mm. between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm. objective.

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

• A NEW AND IMPORTANT ADVANCE IN MICROSCOPY

The Interference Microscope represents the very latest development in microscopical optics. Already researches utilising the new instrument have been published in *Nature* and elsewhere.

In monochromatic light the images obtained are similar to phase-contrast images, but with continuously variable phase-change adjustment and a considerably greater sensitivity. The optical artifacts associated with phase-contrast are noticeably absent; whilst in white light the images are seen in colour contrast. The instrument is easy to set up and to adjust.

The microscope enables small phase-changes, under good conditions down to $1/300$ wavelength, to be measured. From these phase-change measurements the dry-mass of cells and other microscopical bodies can be calculated and refractive indices determined.

The Interference Microscope, in either double-focus or shearing form, is now available for delivery; please forward enquiries to

CRYSTAL G(r)AZING

... Reveals the facts on

**ALL SURFACE
STRUCTURES**

Polished diamond facet showing crystalline structure of surface layer.

The electron diffraction camera is a striking example of the way in which high vacuum has harnessed the electron to provide a powerful research tool for investigating and recording surface phenomena, e.g., lubrication, oxidation, catalysis and micro-quantities of metal, ceramics, plastics and polymers, etc.

The latest EDWARDS camera offers diffraction workers a high performance standard with a most convenient centralised control system—all controls, including that of the remotely situated H.T. system (to eliminate any electrical interference), are compactly grouped on the camera body.

for better vacuum service...

STANTON *Leadership*

The design and construction of every modern Precision Balance manifests the Influence that STANTONS have exerted during the past few years

STANTON were first with:

- Synthetic Sapphire (Corundum) Planes.
- Full weight-loading balances in Britain.
- Balances with a special application—e.g., Gas Density Determination, Thermo Recording Work, Remote Control Work.

STANTON *now present 2 new models*

Model A.D.3

Capacity: 200 g.
Sensitivity: 0.1 mg. per half division

This aperiodic, projection-reading balance provides for external weight-loading of fractions up to 1 g., by means of a single dial. The new graticule reads direct up to 100 mg., resulting in greater weighing speed and less fatigue.

Fully descriptive illustrated poster on request

Model B.A.9

Capacity: 200 g.
Sensitivity: 0.1 mg. per half division

This balance represents another contribution by Stanton towards greater balance room efficiency. Only four dials give weight-loading up to 200 g. —Graticule reads direct up to 100 mg., and complete weighing can thus be made in twenty to thirty seconds.

STANTON BALANCES are stocked by leading laboratory furnishers

SAMPLING, METHODS FOR CENSUSES AND SURVEYS

FRANK YATES, F.R.S.

This book covers developments of sampling theory of importance in census work. It discusses problems met in the planning, execution, and analysis of sample surveys, with fuller treatment than in text-books or in courses on statistics. This second, revised edition amplifies certain aspects in the light of recent advances and devotes a chapter to investigational surveys, as distinct from census surveys, with instructive examples.

PRECISION

INSTRUMENTS

Jamin Refractometer

for liquids or gases

Average accuracy in measurement of refractive index is approximately 0.000001 for gases and 0.000002 for liquids.

The elimination of all spring adjustment to the mirrors results in great stability and freedom from vibration. Worm wheel gearing actuates the compensator. Tubes up to 50 cm. length can be used.

RESEARCH PLANNING AND POLICY

DR. VANNEVAR BUSH, president of the Carnegie Institution of Washington, as witness his recent annual address to the Institution, and the trustees of the Nuffield Foundation and like bodies are much concerned at the present time with the relations between scientists and administrators in research planning and policy. Some of their problems were examined by Mr. C. V. Kidd in an article in *Science* last year (112, 147; 1953). He directed attention, as Prof. M. Polanyi has done, to the limitations which science itself sets on the freedom of a particular investigator, and he finds a solution to this problem of reconciling initiative and freedom with the direction or planning of research through the recognition that decisions should only be taken at the appropriate level. Those responsible for the decisions regarding the deployment of resources should not attempt to make the decisions regarding the execution or details of particular projects or experiments. Their decisions may and do set limits within which those responsible for the leadership of groups or the carrying out of specific investigations must lay their plans; but particularly in fundamental work, there should be the greatest possible freedom to select work, as well as to choose means, and to deviate from any predetermined plans.

These arguments, from various quarters, afford ample justification for the concern which has been expressed as to the consequences of excessive dependence of American universities upon Federal funds for the support of their research activities. The independent research institution organized on the lines indicated by Dr. Bush and concentrating on finding the outstanding man and giving him his head is not merely well qualified to sponsor investigations in fields neglected by other bodies and where the prospect is too speculative to justify the commitment of public resources; it offers at least as good prospects as anywhere else of securing the general agreement and understanding as to the choice and conduct of particular investigations which provide the appropriate atmosphere for creative work and the guidance and development of individual genius. Such conditions are, of course, equally to be found in the universities, and it is by no means certain that the independent institution enjoys quite as much advantage over the university as Dr. Bush suggests. Freedom from teaching responsibilities may be an illusory advantage unless there is something in the contacts between research workers in different disciplines or branches of science which provides the same stimulus, interchange of ideas and inspiration as the close intercourse of different subjects and inter-education of teachers of one subject by those teaching another which Sir Ernest Barker notes as one of the great advantages of the tutorial system at Oxford.

Dr. J. D. Millett's report for the Commission on Financing Higher Education shows clearly that responsible opinion in the United States fully recognizes both the inevitability of sponsored or contract

research, and also the dangers inherent in such research especially when it is sponsored by the Federal Government; nor is there any attempt to disregard the complexity of the issues involved. Probably the greatest danger is that of balance: both staff and other resources are liable to be deflected into specific lines of inquiry, often of a development type, to the neglect of fundamental research. There is also the question of stability arising from uncertainty as to the duration of support; and other questions may arise such as the academic status of the research staff involved and the secrecy requirements hindering exchange of information or publication of results.

Here the principles laid down by President H. W. Dodds, of Princeton University, in a recent statement published in the *American Scientist* (42, 128; 1954) offer sound guidance; and they are supported by Dr. Millett's comment that much of this development work proceeds at best on a basis of trial and error because the requisite fundamental knowledge is lacking. Indeed, he goes so far as to suggest that at least half the cost of much applied research in the United States to-day could have been avoided if more basic knowledge had been developed in their universities. Government support of research has proved its value; but the problems which it has brought, notably that of duration, has demonstrated that it does not by itself solve the financial problem of fundamental research. It has, in fact, as Dr. Millett points out, enhanced the importance of other sources of income if universities are to maintain their independence and balance.

Fortunately, it is clear from this report that the prospects of independent benefactions, quite apart from the activities of the independent research institutions or foundations, are brighter in the United States than in Britain. It is not considered that this is a negligible and dwindling source of income, and so long as the present dependence of universities upon Federal funds for support of fundamental research exists, it appears to be possible that income from this source may offset any falling off in the volume of research supported through the defence agencies and especially on a contract basis. How far this hope is justified may well appear doubtful to the disinterested observer, in view of the attitude hitherto adopted by Congress to the National Science Foundation. Although, as Dr. Millett reminds us, a very strong argument can be advanced that the security of the United States is best served by a policy of promoting fundamental research in preference to development research, Congress will have to show a marked change in outlook before real confidence can be felt that it is likely to endorse the continuing support of fundamental research at the universities in the natural sciences by appropriations through the Atomic Energy Commission and the defence agencies which at present administer so much of this expenditure.

Apart, moreover, from the questions of balance and of the discretion to be left in the hands of the university administrators rather than government officials, there are important questions of co-operation—

between universities themselves, and between them and the independent research institutions which have hitherto received little attention. It is here that Dr. Millett's analysis of the criticisms of the independent research institutions is valuable. He accepts the view that these institutions—because of their independence—are right to be adventurous, to explore unpopular subjects, to survey fields which government and other agencies shun and to encourage promising talent that has not yet established a reputation. If, however, these bodies are to avoid long-term commitments, and leave to other agencies the task of carrying to completion their successful explorations, there is substance in the frequent criticism of the short-term character of their grants. A measure of co-operation and concerted policy is required at this point, and though it may well in practice come by informal rather than by formal means, neither in the United States nor in Great Britain has the difficulty been entirely resolved.

Probably the inquiries of the National Science Foundation will assist to that end in the United States. In Britain it is obviously engaging the attention of the University Grants Committee, as can be seen from the reference to ear-marked grants in its last report. Neither that body—nor any one formal body—is so constituted as to be able to deal with the problem in all its aspects, though some guidance might well come from the Office of the Lord President of the Council on particular issues. Beyond that it is one to which the Parliamentary and Scientific Committee or the Federation of British Industries could perhaps offer an informal contribution at the appropriate moment, through a joint conference such as those which Nuffield College, for example, arranged some ten years ago on industry and education and on problems of scientific and industrial research.

The second criticism noted by Dr. Millett, that the project approach concentrates attention upon research rather than upon instruction, is scarcely relevant in the present context and in Great Britain. The independent research institution is concerned, by its nature, primarily with the advancement of knowledge, and its contribution to the training of research workers is most effectively made by the continual movement back to the universities or into industry or Government research institutions of young investigators whom it has picked out and trained. The industrial research associations cannot be described as independent research institutions in the sense in which we here understand that term, but it may be noted that part of their proved value to the industries they serve lies in the supply of trained scientists and technologists to these industries, and the educational functions of the research associations are in fact being increasingly stressed. Even the advantages of teaching noted by Sir Ernest Barker would not, however, justify deflecting the work of the research institution from the investigations for which it was established to the task of instruction.

By and large, the research institution's contribution to instruction is made by the continuous process of interchange of workers; and that contribution will be

the more fruitful the more the organization of its projects is such as to avoid the departmentalism which is liable to characterize a university, and to encourage the contact or even conflict of minds across different disciplines which is so fruitful of new ideas. A further criticism, that foundations tend to transfer to their own staffs those functions of the choice of projects for support and the magnitude of the support to be given, has more justification and bears somewhat upon this point. Both points of view will call for constructive thinking in order that frustration and waste of effort and resources may be avoided. President Dodds and Mr. Kidd give indications of the solution, and close and informal contact between the staff of a foundation and the university or research institution such as a reasonable and constant interchange fosters can do much to keep decisions within the appropriate level without encroaching on the competence of others.

It seems clear from these studies that while rather more concern is felt in the United States as to the long-term effects of increasing Federal support of research, the prospects of continuing support from independent voluntary sources are better there than in Great Britain. At least while the present level of taxation persists, it is difficult to give a confident affirmative answer to Lord Beveridge's question whether the succession to the Webbs is secured. Whatever the device with which the society of the future ensures that the spiritual successors to the Webbs have their material resources for research, untrammelled by other duties, by orthodoxy or by prescription of topics, the independent research institutions and the universities will have an essential part to play. That of the Government may well lie less in the direct provision of resources than in seeing that national policy is such that neither fiscal, economic nor any form of political pressure is allowed to discourage initiative, enterprise or the free interchange of minds and exchange of ideas which are the basis of creative activity and the advancement of knowledge in any field.

IN HONOUR OF CHARLES SINGER

Science, Medicine and History

Essays on the Evolution of Scientific Thought and Medical Practice written in honour of Charles Singer. Collected and Edited by E. Ashworth Underwood. Vol. 1: Pp. xxxii+563+50 plates. Vol. 2: Pp. viii+646+56 plates. (London: Oxford University Press, 1953.) 2 volumes £11 11s. net.

CHARLES SINGER, never more learnedly active or intellectually alert than now, in his seventy-eighth year, is a great figure in the history of science, whose influence goes far outside those academic circles to which many of those dedicated to his discipline are restricted. His services in the sphere of learning that he has made his own cannot be set down in a few words, but they comprise outstanding original work in the history of medicine; pioneer exertions as a teacher and as a promoter of the

teaching of the history of science; the writing of general text-books; the production of choice and beautiful books for more specialized readers; and the fostering of international co-operation between scholars devoted to the history of science. The two volumes of "Studies on the History and Method of Science", which he edited and to which he contributed outstanding articles, have become much sought-after rarities. Very fitly he is a doctor of medicine, science and letters, for he is Hippocratic, learned and lettered. He has, in the course of a life characterized by a warm-hearted enthusiasm, an informed curiosity and far travel along both the highroads and byroads of learning, gathered together a great body of friends, all gifted but with diverse gifts, and some time ago one prominent among them, Dr. E. Ashworth Underwood, undertook the organization of a tribute of admiration and affection from these many men. The present two imposing volumes comprise the essays, ninety in number, offered in homage to one who is the founder of a great and world-wide school of historical research. Dr. Underwood set out on his pious and laborious task many years ago, and since the start fifteen of the authors, including such veterans as dear D'Aroy Thompson, have passed away. To bring together and to edit so many contributions, many of them from distant lands, inevitably takes time. The result is impressive. Dr. Singer has the first claim on our congratulations, the contributors a first claim on our thanks, but Dr. Underwood deserves an ample share of both.

It is not easy in a necessarily restricted space to do justice to studies so numerous, all of great merit and many of outstanding interest, by so many authors, all of profound learning and many of international fame, where the selection of some may seem to suggest, quite wrongly, that all the others are less worthy of note. The variety accords well with the range of the Singers' interests—for Dorothea Singer stands by the side of her husband in these celebrations as in erudite and domestic sympathy. The international character indicates the wide-spread scope of their friendship, for, besides many outstanding contributions from the United States, there are offerings from at least seven European nations. The essays are grouped chronologically in seven "Books" or sections, beginning with the ancient world, Egypt, Greece and Rome. This first section includes an unexpected article on "St. Augustine and Magic", by Dr. Claude Jenkins, in which we find already the legend that the presence of diamonds inhibits the attractive virtue of the magnet, a belief accepted so widely and so late that William Gilbert carried out an elaborate experiment to prove that it was baseless. The next section deals with the medieval world, where we have articles of profound scholarship in remote byways of ancient learning, such as that by Dr. H. E. Sigerist on a fifteenth-century manuscript by Johannes Hartlieb, an early German humanist who brought together gynaecological treatises, and that by Chaim Rabin on the writings of Ibn Jami, who was physician to Saladin. Names more familiar figure in Dr. Sherwood Taylor's erudite and entertaining article on the Quincentenary. Book III brings us to the Renaissance, with, corresponding to his importance, three studies on different aspects of Vesalius. Agnes Arber, an old friend to whom Singer dedicated his "Short History of Biology", is, luckily, well represented by a study in a subject in which she is

paramount, "From Medieval Herbalism to the Birth of Modern Botany". In this group, too, we find a delightful example of light-hearted learning in an essay by Prof. F. J. Cole on Dürer's rhinoceros. It was in 1515 that the artist executed his famous drawing and woodcut of the Indian rhinoceros, or "Gomda", as he called the beast. The eminent zoologist traces Dürer's picture—incidentally, he had never seen a rhinoceros, alive or dead, when the drawing was made—through all the copies, adaptations and transformations down to its last appearance in 1769, with a delightful series of reproductions. Another unexpected study illustrating the diversity of the collection is that, in Book V, by Dr. H. J. Norman on John Bulwer, the seventeenth-century author of "Anthropometamorphosis", a treatise on the deformities and decorations of the human body produced in all parts of the world by fashion. It was a work often cited in Victorian attacks on tight-lacing, but is not much heard of nowadays. A drawing by Daumier comes as somewhat of a surprise in scholarly surroundings, but it illustrates appropriately Dr. Paul Delaunay's brilliant little essay, in Book VII, on P. C. A. Louis as the founder of medical, as distinct from vital, statistics.

To return to our ordered survey, the fourth Book, entitled "The New Philosophy", deals with the period of the reaction against Aristotle and with the beginnings of modern science, while the fifth is concerned with the seventeenth century in general. Here Dr. Arnold Sorsby contributes a very informative article on Richard Banister's services to ophthalmology, the importance of which, we believe, he was the first to stress. Incidentally, articles of ophthalmological interest in the whole work range from Dr. Kurt von Fritz on Democritus's theory of vision to Dr. Dorothy Turner on Thomas Young's work concerning the same subject. Attention may be directed to Dr. Max Fish's detailed and fully documented study of the little-known *Investiganti* of Naples, an academy which flourished at the time of the *Cimonto* of Florence and continued to exist until 1737.

The eighteenth century likewise has a Book to itself, in which Dr. Underwood's contribution is one of the most considerable and, so far as I am able to judge, most original studies, dealing as it does with the text-book of physiology, to use modern terms, written in 1701 by Johann Gottfried von Berger, a name not mentioned in Garrison's "History of Medicine" or other well-known histories of the subject. The Book on the nineteenth century and after contains seventeen papers, of which Sir Geoffrey Jefferson's very frank but sympathetic treatment of Marshall Hall's work on reflex action is certainly not the least interesting.

The book concludes with a series of studies of general import contributed by famous names, such as Dr. Redcliffe Salaman, Dr. John Fulton, Prof. C. D. Darlington and Dr. Joseph Needham, as well as, among younger men, Mr. H. T. Pledge. Perhaps it is typical of the quality and scope of the whole collection that whereas the first essay of all is a brilliant survey of the growth of archaeology to its modern position as a science, by Prof. Gordon Childe, the last is a charming collection of reminiscences by Charles Sherrington, whose early hero, Fernal, figures frequently in the essays. This brings to mind a feature of the editing that deserves a special word of commendation, namely, the indexes of persons and subjects, which are particularly full, well

designed and well carried out, and are an invaluable addition to a work of this kind. Thus, if one wants to know what is said of Fernal in different places, one has only to turn to his name to find the various references descriptively set down, not just paged.

Famous names, in themselves a guarantee for the excellence of their contributions, which have not even been mentioned are Dr. George Sarton, founder and editor of *Isis* and *Osis*; Prof. J. R. Partington; Dr. Gavin de Beer; Sir Zachary Cope; Prof. Herbert Dingle; and Dr. Douglas McKie—and there are others. The survey which this notice has been able to offer is slight, the selection of essays for mention arbitrary; all that can be hoped is that the reader will have gathered the impression that here is a book which any lover of learning, especially one with historical and bibliographical tastes, can pick up, open anywhere and read with the greatest pleasure and profit, or, alternatively, of which he can in lazy mood turn the pages, look at the pictures and read odd passages, to be lured to more serious attention. It is an ideal book to take up for after-dinner entertainment, a hard book to put down. Let us conclude with a quotation from D'Arcy Thompson's feeling study entitled "The Golden Age", in which he considers how particular periods have been outstanding in different countries for exceptional achievement in science and art—"But we may turn from the way-side and the market to watch the kindly faces of a little company of unworldly men. They are not (as I see them) the faces of statesmen, nor warriors, nor even artists, authors, poets: they are just the earnest student-faces of far-seeing and deep-thinking men"; and after the citation of great names in science of the period from Faraday to Rutherford and Planck—"Some of these dwell among the Gods, the rest are Heroes. And our children's children will look back on the great century of science to which they belong, and will know it for a Golden Age".

E. N. DA C. ANDRADE

FRESHWATER ECOLOGY

Fundamentals of Limnology

By Dr. Franz Ruttner. Translated by Dr. D. G. Frey and F. E. J. Fry. Pp. xi+242. (Toronto: University of Toronto Press; London: Oxford University Press, 1953.) 52s. net.

THOSE engaged in teaching freshwater biology have for long felt the lack of a satisfactory text-book, and many must have wished Prof. F. Ruttner's "Grundriss der Limnologie" were available in English. This wish has now been answered by two professors, one American, the other Canadian, who both set out independently to translate the book and only heard through a mutual friend in Scotland of each other's intentions. The result was their collaboration in the present volume.

The first half of the book gives a clear and concise account of "Water as an Environment" in two sections covering respectively the "Physical Properties of the Environment" and "Dissolved Substances and their Transformations". The approach is essentially ecological, and the information is presented as the physico-chemical background which is fundamental to an understanding of the biology of fresh waters. The second half is devoted to "Biotic Communities" and is divided into four sections of unequal length covering plankton, and other communities of lakes,

bogs and running water. The longest and most interesting of these is that on plankton. Here the author's point of view is primarily, though not exclusively, chemical; but what is known of the physiology of the organisms is also taken into account in discussing their ecology, and occasional comparisons with the sea are illuminating. If there are aspects of the subject which receive rather scant treatment, this is compensated by the author's stimulating ideas on others. This section really hangs very closely on to the first half of the book.

With the change of subject to "The Other Communities of Lakes" the treatment becomes much less exhaustive, and one is conscious that the author is a little outside his own particular field. But the section on "Communities of the Ooze", where the point of view is again mainly chemical, is as interesting and stimulating as anything in the earlier parts of the book. There is here an admirably lucid exposition of the fundamentals of this intricate and complex system.

The translation is so good that one is only very occasionally reminded that the original was not written in English, and there is a useful list of the words the translators have adopted as equivalents for some of the technical terms of the subject. While some of these seem too obvious to be worth mentioning, one wonders what led them to coin the words 'highmoor' and 'lowmoor' [sic] for *hochmoor* and *flachmoor* instead of using 'raised bog' and 'valley bog', respectively. It may be that limnologists do not use these terms as precisely as plant ecologists; but these do in fact seem to be the senses in which Prof. Ruttner uses them.

But the smallness of these criticisms is an indication of the general excellence of the book, a fact which no limnologist would dispute. Not only does it gather together much of the information scattered in the literature and weave it into a well-knit whole, but it also throws a flood of light on Prof. Ruttner's insight into many of the problems of the subject in a way which none of his previous publications do. The only amendment I would propose to the translators' assessment of it as "perhaps the best book available in any language on the principles of limnology" would be to substitute "undoubtedly" for "perhaps". All British and American workers in the subject will be grateful to Profs. Frey and Fry for making it available in English.

H. C. GILSON

HEALTH AND SICKNESS IN BRITAIN DURING WAR-TIME

The Civilian Health and Medical Services

Edited by Sir Arthur Salusbury MacNalty. Vol. 1: The Ministry of Health Services; Other Civilian Health and Medical Services. (History of the Second World War: United Kingdom Medical Series.) Pp. xi+441. (London: H.M. Stationery Office, 1953.) 45s. net.

"WAR is the enemy of health." Yet wars in our recent history have been a direct stimulus to progress in medical science and the development of health services. This volume tells the remarkable tale how, after a brief set-back in the early days of the Second World War, steady improvement in the public health went on in Great Britain as measured not merely by falling mortality-rates but more

positively by steady advance in the physical development of the nation's children.

No doubt we were lucky in some of our escapes from epidemic diseases, for example, the long-awaited and much-dreaded influenza epidemics which never came. But it was by no means all luck. Intensive planning for the war emergency began at the Ministry of Health two years before the outbreak of war, and the British Medical Association along with the Royal Colleges of Surgeons and of Physicians played their part by preparing, and later carrying out, the mobilization plan for the medical profession.

War gives courage to make long-needed reforms. The Emergency Public Health Laboratory Service was one of the great innovations of the War. Yet Sir John Simon had foreseen the need last century, and his successor at the Local Government Board, Sir Arthur Newsholme, pressed the need for it, in season and out, and would have achieved his object but for the outbreak of the First World War. This Service was introduced in anticipation of great epidemics. These never materialized, but the laboratories were brought into permanent place in our health services by Dr. G. S. Wilson's bacteriologists, who did much to raise national standards of diagnosis. Chlorination of water supplies was introduced against the increased risk to water supplies from air raids and lesser war-time threats, and this, too, became a permanent feature of our public health control. The diphtheria immunization campaign was one of the great achievements of the War; its importance can be measured against the experience of the Channel Islands, which were exposed to the severe Continental epidemic of diphtheria in 1942-43. The Ministry of Health was allowed to introduce by radio frank and realistic discussion on venereal diseases, and public opinion, well ahead of its guardians as often, received this without dismay.

The epidemics of cerebro-spinal fever during the years 1940-42 were sharp and unpleasant, and followed precedents established during the Napoleonic Wars, the American Civil War and the First World War. We were more fortunate than our forbears because of recently developed and effective chemotherapy against this killing disease. Epidemic hepatitis was another traditional war-time disease which gave a good deal of trouble. No specific remedies were available; but a great deal was learnt about the natural history of the disease, and the related scourges—serum jaundice and post-transfusion jaundice, this latter being a bitter by-product of the brilliantly successful war-time blood-transfusion services.

Our fortune with tuberculosis was mixed. In the early days of the War chronic infectious patients returned home from sanatoria beds emptied in anticipation of air-raid casualties. This and war-time conditions brought a rise in the tuberculosis death-rate during 1940-41. Among adults it was older men, not young women, as in the First World War, who fared worst. The most disquieting feature was the increase in deaths among young children from pulmonary tuberculosis and meningitis. Later the tuberculosis death-rates resumed their pre-war downward trends. Notifications, however, continued to rise, partly at any rate due to improved means of diagnosis, and with rising notification-rates came prolonged waiting-lists for admission to sanatoria. The threat from tuberculosis had its valuable achievement in certain innovations, notably the introduction of mass miniature radiography and the system of

tuberculosis allowances to encourage the early diagnosed case to accept treatment.

Undoubtedly the greatest achievement of all was in the field of nutrition. The rationing policy was the result of pre-war research. Long before the War, emergency food policies had been outlined, and at the outbreak of hostilities the new Ministry of Food accepted as the essentials of its policy not only the need to economize in shipping space but also the equitable distribution of food, with special attention to those on whom the future depended—that is, children and expectant and nursing mothers. Apart from rationing, the raising of the extraction-rate of flour, the development of school milk and meals, and the encouragement of factory canteens were important features of policy.

It is an unexplained wonder that the overcrowding in air-raid shelters produced so few ill-effects. After the first crisis and blundering of the 'blitz' were over, devoted efforts were directed to the improvement of sanitation and ventilation in the shelters and to the development of medical services and epidemiological studies. All these things must have helped, but they do not explain the providential escape from disease.

Not least among the effects of the 'blitz' was the introduction to each other, through the evacuation, of Disraeli's two nations. The discovery that head lice, impetigo, ringworm and bed-wetting were common was a surprise only because we had shut our eyes to these things in peace-time. In coping with these problems, the School Medical Service played a major part, and it should not be forgotten that the Education Act of 1944, passed in war-time, was an important health act as well as a new policy for education.

In industry, too, there were notable advances. The Factory Department was transferred to the Ministry of Labour and National Service in 1940, and played its part under that Ministry in mitigating the strains of war-time production and black-out conditions. The Factories (Medical and Welfare Services) Order 1940 had its outcome in the spread of medical and nursing services in industry, and in the multiplication of industrial canteens. The Ministry of Supply developed its own industrial medical service to control the serious toxic hazards in ordnance factories, and with a considerable measure of success.

Not least among the interests of this volume is the story of the health services of the Channel Islands during the German occupation. Finally, as a commentary on Britain in war-time, it is worth recalling that the first planning and negotiations for the National Health Service began early in 1943 when the end of the War was still very far from view.

J. H. F. BROTHERSTON

HEALTH AND SAFETY IN AVIATION

Human Factors In Air Transportation Occupational Health and Safety. By Prof. Ross A. McFarland. Pp. xv+830. (London: McGraw-Hill Publishing Co., Ltd., 1953.) 108s. 6d.

IN an earlier book, "Human Factors in Air Transport Design", Dr. R. A. McFarland, who is professor of industrial hygiene at the Harvard School of Public Health, made an admirably bold

and very useful attempt to provide designers of aircraft with information about ways in which they should 'make allowance' for human capacities and inclinations in their aeronautical engineering. In the present book he goes several stages further and offers a multitude of facts and opinions to specialists in aviation medicine, personnel managers, safety experts, and to many more; and, as before, he performs his task in a thoroughly businesslike fashion. Not the least commendable feature of the book is its lucidity. There can be no doubt that from this point of view it will prove an unusually acceptable guide to the layman. Dr. McFarland takes an immense amount of trouble to make himself clear. This shows itself not only in his careful explanation of technical points in ordinary language, but also in his thinking about them (for example, in his use of the subtentative, assumption-free term 'accident repeater', on p. 78, for the adjectival, theory-ridden 'accident prone').

The ground he covers is clearly indicated in his well-planned contents pages. After an introductory chapter, which finishes with an assertion of the view that the ultimate success of air transportation will depend on the extent to which the characteristics of its operating and maintenance personnel are understood and the social habits and needs of its passengers recognized, he goes on to deal with the selection and training of flight personnel and the selection, placing and health of ground personnel. He ranges widely in these fields and presents a number of useful summaries of work done in them, particularly during the Second World War. But sometimes he attempts so much that he lays himself open to a charge of superficiality. Indeed, some of his efforts at condensation lead to rather puzzling statements. For example, on p. 41 he remarks, "Once the tests were found to be of predictive value, the next step was to determine a valid criterion for success in combat". He may perhaps argue that the context made it unnecessary to add the words 'for success in training' after 'predictive value', but surely the saving was scarcely worth while. Again, on p. 75 he appears to fall into the common trap of regarding rating scales as instruments for producing judgments rather than as mere recording devices. Faults of these kinds will not seriously diminish the value of the book to knowledgeable readers, but they may mislead the non-expert.

Dr. McFarland's chapters on safety on the ground and in flight make good reading, not least because they give him scope for his obvious taste—already displayed in his chapter on the indoctrination and training of flight crews—for formulating plain rules of procedure, securely rooted in careful reflexion on relevant evidence. He seems equally at home in his chapters on sanitation and health in airline operations; but—not unnaturally—he is rather less confident when he comes to examine problems arising in the care of passengers and the transportation of patients by air, for in many respects these must be regarded as relatively new. In his final chapter, Dr. McFarland discusses the organization and functions of air-transport medical programmes. So wide and deep is the territory he wants aviation medicine to annex, that a bystander may well wonder where people competent to administer it will be found in the numbers that this immense work will require. But no harm can be done by his thoughtful exposition of his grand ideas. Anyway, it makes a fitting end to a fascinating book.

ALDO RODGER

Organic Syntheses

An Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. Vol. 32; 1952. Edited by Richard T. Arnold. Pp. vi+119. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1952.) 28s. net.

OF the forty-five preparations described in this volume, the first is an improved method for preparing abietic acid from wood resin; and the last deals with the conversion of 10-undecenoic acid into 10-undecynoic acid, the double bond being converted into a triple bond by successive treatment with bromine and sodamide. Other methods of introducing triple bonds are illustrated by the use of acetylene and of calcium carbide in the respective preparations of β -chlorovinyl isomyl ketone from isocaproyl chloride and of 1,1'-ethynylene-bis-cyclohexanol from cyclohexanone. The great variety of processes here displayed may be illustrated further by mentioning the preparations of alloxan monohydrate from barbituric acid, cyanogen iodide from sodium cyanide and iodine, 1,2-cyclohexanedione-dioxime from cyclohexanone, and cyclohexane sulphide from cyclohexene oxide. While a new method, due to Prof. T. S. Wheeler, is given for the direct production of flavone from *o*-benzoyloxyacetophenone and anhydrous glycerol, the application of the Baker-Venkataraman transformation is recommended because of the high yield and reproducibility of this procedure. Essential precautions and experimental detail are admirably set out: for example, in preparing 2,2-dichloroethanol from dichloroacetyl chloride and lithium aluminium hydride, the use of a good hood and a spark-proof motor is prescribed; glassware is dried by flaming during the passage of dry nitrogen, and directions are given for pulverizing the hydride. The subject index covers Vols. 30-32.

JOHN READ

Toxicity of Industrial Organic Solvents

By Ethel Browning. (Revised in consultation with the Toxicology Committee.) (Medical Research Council: Industrial Health Research Board, Report No. 80.) Revised edition. Pp. viii+412. (London: H.M. Stationery Office, 1953.) 35s. net.

IN this revised (1952) edition, Dr. Ethel Browning has summarized, in the light of the results of work published up to the year 1948, the toxic action of some organic solvents and the possible effect of this on the health of workers in industrial processes where these solvents are used. The summary includes both the older and better-known solvents, and also some which have only recently become available in commercial quantities. The new edition appears at an opportune time, since solvents of all kinds are being used in increasing quantities in a variety of industrial operations.

The arrangement of the subject-matter follows closely that adopted in the first edition. For each solvent the relevant physical properties are listed, together with the requirements of any existing recognized standard specification for controlling the quality and composition of the solvent. The importance of some knowledge of the chemical composition of the solvent, in relation to any toxic effect observed in its use, is indicated by the author in comments on the results of some of the published work. The symptoms which characterize cases of acute and chronic poisoning, in both animals and man, are fully described, and for a number of solvents

useful data are given as to what, in the opinion of some authorities, should be regarded as a maximum safe concentration of the solvent vapour in air.

The book is a worthy successor to the first edition, and should prove of considerable help to all concerned with the health of workers in the manufacture, transport or use of organic solvents.

Volumetric and Phase Behavior of Oil Field Hydrocarbon Systems

By Dr. M. B. Standing. Pp. vi+123. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1952.) 80s. net.

THE complex behaviour of varied types of hydrocarbon systems encountered in oilfield reservoirs has engaged the attention of petroleum engineers for many years past. Much has been done and much written on specialized methods of calculating pressure-production characteristics of subsurface oil and gas pools. This volume approaches the subject from the less conventional angle—co-ordination of laboratory measurement data on fluids, and the manner in which these data can be used to calculate actual reservoir behaviour. When we consider that under normal oilfield conditions vastly different hydrocarbon systems are co-existent; that types vary from a simple gas such as pure methane to the highly complex asphaltic bitumen; and that these types are constantly changing with pressure and temperature as affected by production; then it at once becomes apparent that problems to be faced require for their solution a sound knowledge of mechanism of fluid flow, thermodynamics and a nicely balanced interpretation of all facts elicited. Treatment of the subject in this book is systematic, based on division of hydrocarbon types into gases, condensate systems and dissolved gas systems. Phase behaviour of these systems, sampling of oil reservoirs and material-balance calculations support the discussion. Numerous charts are included to aid calculations for specific reservoir conditions, and the general set-up of text and clear printing add greatly to the value of the work, without which oil-pool specialists will lack a very modern approach to this ever-difficult subject.

H. B. MILLER

Contributions to the Theory of Nonlinear Oscillations

Vol. 2. By M. L. Cartwright, E. A. Coddington, H. F. DeBaggis, S. Lefschetz, N. Levinson, J. McCarthy, H. L. Turrittin. Edited by S. Lefschetz. (Annals of Mathematics Studies, No. 29.) Pp. vii+116. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1952.) 10s. net.

THIS monograph is a sequel to No. 20 of the same series. The following articles appear in it: Van der Pol's equation for relaxation oscillations (Miss M. L. Cartwright); perturbations of linear systems with constant coefficients possessing periodic solutions (E. A. Coddington and N. Levinson); dynamical systems with stable structures (H. F. DeBaggis); notes on differential equations (S. Lefschetz); a method for the calculation of limit cycles by successive approximation (J. McCarthy); and asymptotic expansions of solutions of systems of ordinary linear differential equations containing a parameter (H. L. Turrittin). These represent contributions to the theory of differential equations; and virtually no attempt is made to discuss physical significance, let alone practical utility of the topics discussed.

THE ROYAL SOCIETY OF ARTS

BICENTENARY CELEBRATIONS

THE first official meeting of the Society of Arts took place on March 22, 1754, and the exact anniversary two hundred years later fell on a Monday, so that the first day of a week of celebrations was also in some respects the most important.

On March 22, 1954, three events were arranged, two of them of more or less public character and the third private. The celebrations opened with a service at the Church of St. Martin-in-the-Fields, when the Society met probably for the first time in its history in such a building and for such a purpose. But the service was unusual not only because of its uniqueness in the Society's history, but also in its own character, and particularly from the musical point of view. As the organ was under repair, the singing was accompanied by an orchestra which, together with the choir, was provided by members of staff and students of Trinity College of Music, under the direction of the principal, Dr. Greenhouse Allt, who is a Fellow of the Society. One item of music was of special interest, the Trio Sonata No. 2 of Thomas Augustine Arne, who was one of the early members of the Society. The sonata has only recently been published, and this was probably its first public performance for 160 years. The execution of the music was throughout of a very high quality and the *Te Deum* (Vaughan Williams in G) in particular formed a most impressive climax to the service. The sermon was preached by the Bishop of Peterborough, who reviewed from the spiritual point of view the bewildering scientific and material progress of the past two hundred years and closed with the words of Francis Bacon: "The final end of all knowledge is the glory of the Creator and the relief of man's estate".

In the afternoon the chairman of Council, the Earl of Radnor, who is the lineal descendant of the Society's first president, Viscount Folkestone, received congratulatory addresses from representatives, in most cases the presidents, of nearly sixty other organizations, many of which, and in particular several from overseas, owe their origin in some degree to the activities of the Royal Society of Arts. It was a colourful scene as the representatives, many of them in academic robes, advanced singly, and with a quiet dignity befitting the eighteenth-century room in which the ceremony took place, to present the tribute of their organization. The ceremony concluded with a short address from Lord Samuel, retrospective but never nostalgic, in which he called upon the members of the Society of the present day to exercise the same faith and hope as moved the Society's founders and to sustain their good work for the sake of the generations that are still to come.

The day's events concluded in a more private manner, when the members of the Society's Council and their ladies dined informally at Tallow Chandlers Hall, and in this way commemorated the fact that the Society's first meeting took place in somewhat similar surroundings at Rawthmell's Coffee House. After dinner, students of the Royal Academy of Dramatic Art presented a scene from "She Stoops to Conquer": Goldsmith was not only one of the early members of the Society, but was also actually an applicant in 1760 for its secretaryship.

On the afternoons of Tuesday, Wednesday and Thursday a series of three masterly addresses was

delivered by Prof. N. B. L. Pevsner, Sir Ben Lockspeiser and Sir Geoffrey Heyworth, on the progress of "Arts", "Manufactures" and "Commerce" respectively during the past two hundred years, this pattern of themes being based on the Society's full title, "The Royal Society for the Encouragement of Arts, Manufactures and Commerce". Prof. Pevsner concentrated mostly on the history of industrial design during this period and, while recounting its promotion by the Society at various periods during the two hundred years, particularly emphasized the influence which it exerted in the years succeeding the Great Exhibition by its forthright attitude to contemporary design. Sir Ben Lockspeiser, in a survey of science in its application to industry during the past two hundred years, looked back, as it were, to Prof. Pevsner's lecture and emphasized the need for improved technology to go hand-in-hand with imaginative design, and looked forward to Sir Geoffrey Heyworth's subject, hinting at the contribution which science can now make to accountancy and many other clerical operations. In the last of the three lectures Sir Geoffrey Heyworth, in dealing with the subject of "Commerce", concentrated his attention upon the history of education for commerce, to which the Society itself has made and continues to make so important a contribution, and, in surveying the past two hundred years, he showed what had been achieved, first by the ordinary day school, then by institutions mainly operating in the evenings for specific training for commerce, and finally, through the acceptance of commercial subjects as appropriate to a university.

The fitting conclusion of the week's celebrations was a banquet, the first official dinner of the Society for ninety-two years, which was held at the neighbouring Savoy Hotel on Friday evening and at which T.R.H. the Duke and Duchess of Gloucester were present. Lord Woolton, a Fellow of the Society, represented Her Majesty's Government, and the Lord Mayor of London was there to represent civic government. In proposing the toast of the Society the Duke of Gloucester emphasized three aspects of its character; which he termed its disinterestedness, its humanity and its ability to combine the virtues of youth and age. Lord Radnor replied, and responses to the toast of the guests, which was proposed by Sir Ernest Goodale, were made by Dr. E. D. Adrian, speaking for the men guests and science, and Dame Ninette de Valois, representing the ladies and the arts. Dr. Adrian emphasized the influence which the Society, as a body interested equally in the arts and the sciences, could exercise towards securing that the discoveries of science were applied in a way that was beneficial and not harmful to the community, while Dame Ninette appealed to it for its support for the youngest of the arts.

Fortunately this festive week does not entirely complete the Society's celebrations of its bicentenary, as it is able to look forward to a reception which is being arranged to be held at St. James's Palace later in the year when its president, H.R.H. the Duke of Edinburgh, whose absence at this time was so keenly felt, can hope to be present.

In addition to these special events, the Society is commemorating its bicentenary by several actions of varying kinds. Its bicentenary competition, in which

deas of life in A.D. 2000 were invited, has already been announced. The Council has also decided to institute a medal, to be known as the Bicentenary Medal, which will be awarded annually to a patron of industrial design, and a new history of the Society prepared by Mr. Derek Hudson and the Secretary was published on the day of the bicentenary. Also,

a beautiful badge of office for the Chairman of Council designed by Prof. R. Y. Goodden has been presented to the Society by a former chairman of Council, Mr. J. A. Milne, and the Chairman was invested with this for the first time on March 17 in readiness for the forthcoming bicentenary functions.

KENNETH W. LUCKHURST

SUN NAVIGATION BY ANIMALS

By DR. H. KALMUS

Galton Laboratory, University College, London

IT has for a long time been suspected that sun navigation must play an important part in the movements of homing and migrating animals; but until recently the evidence for its existence was not convincing, often contradictory, and the way in which it could work remained mysterious. However, experiments published during the past two years on honey bees¹, amphipods (*Talitrus saltator*)² and birds^{3,4} have not only demonstrated the existence of sun navigation beyond doubt, but have also shown that it is based in all three groups on a combination of two widely found faculties, namely, the perception and memory of angles and a change according to a twenty-four-hour rhythm of a reference system operating in the brain of the animal. As the orientational behaviour of honey bees is better known than that of the other species, it will be discussed first.

Worker bees, in a dark hive-like container, have been shown to perceive and to remember the angle between two straight parts of a learned track with great facility⁵, and it has long been established that in the outside world they make use of their sense of direction when flying between their hive and a feeding place⁶.

A combination of indoor and outdoor orientation is the basis of the bees' communication of direction: a forager by dancing on a vertical comb in the dark indicates, by the angle and direction of deviation from the vertical, the angle and direction of a rich source of food from the direction of the sun⁷.

It was believed for a long time, and on some evidence, that honey bees, once they have learned the angle between the sun and a source of food, will retain this angle unchanged in their memory and will accordingly, like certain ants⁸, strike out in a wrong direction, when they have been forced by the experimenter to remain inside the hive, the deviation depending on the length of their captivity. Lately, however, v. Frisch¹ has demonstrated that bees "when orientating with the aid of the sun, take the hour of the day into account". During several fine days he fed bees at an anise-scented syrup dish 200 m. west from their observation hive. The colony was then removed to a neighbourhood which was quite unfamiliar to the bees, and four identical syrup dishes scented with aniseed were laid 200 m. to the north, the south, the west and the east from the hive. Within three hours, twenty out of twenty-nine bees marked in the first location at the dish on the previous day were caught at the dish west of the hive and seven at the three others; and this happened although the sun had stood in the west when the bees had last fed at the first place, and in the east when they were caught at the second place. Repetitions of this type of experiment using additional precautions against other clues had similar

results; but the orientation broke down when the sky was overcast. Additional evidence for a mechanism compensating for the daily movements of the sun is provided by an observation by Lindauer¹ on an exceptional dancer, who after having found a dish did not leave the hive after 1-2 min. as is the rule, but continued to dance for eighty-seven minutes on a vertical comb. During this time the angle of the axis of the dance with the vertical changed by about 38°, while the movement of the azimuth at the place and time of the observation was 34.5°. Thus there can be little doubt that bees when finding a direction make use of some device which compensates for the daily movements of the sun or perhaps for the changes in the polarization pattern of the sky associated with it which they are known to use in other circumstances. While the possession of this compensating mechanism must be considered to be innate, its setting—like that of an automatic steering device—is effected for any situation, as opportunity arises.

The second example of sun navigation concerns the little crustacean *Talitrus saltator*, an abundant inhabitant of many sandy beaches in the Mediterranean. These animals when transferred inland will move at a right angle towards the coast-line from which they came, which will normally result in their regaining their habitat. Recently, Pardi and Papi⁹ have shown that to do so they make use of the position of the sun. When the sun was shielded from a few of these crustaceans and was replaced by its mirror image from the opposite direction they moved away from the shore instead of towards it. Like the bees, they could also orientate themselves when in the absence of direct sunlight, provided that some portion of the blue sky, but larger than that necessary for bees, was visible to them, and they could also be deflected by the application of a polarizing sheet. The directions of their movements were independent of the hour of the day, and thus of the changing position of the sun, but dependent on the place of origin of the animals: individuals from a population of the Tyrrhenic coast of Italy, for example, moved westwards, even when brought to the Adriatic coast, while the indigenous animals there moved eastwards. As with the bees, one must assume that the mechanism which compensates for the daily movements of the sun is innate in *Talitrus*, but unlike bees these crustaceans cannot set the geographical direction in which they move by individual experience; it seems to be set for each of them once and for ever either by heredity or by early individual experience.

Similar observations were also made on pigeons, starlings and other birds. Kramer¹⁰, experimenting with starlings, showed that these birds, like *Talitrus*,

have innate direction preferences, which come into play during migration, but that—like bees—they can also be trained to any geographical direction. In both reactions compensation for the daily movements of the sun was observed; but as might be expected from the structural differences between an arthropod's and a vertebrate's eye, the polarization of sky light does not play an important part in this. The innate preference for a particular geographical direction was established by closer observation of a well-known phenomenon: the migration during certain hours of the day of caged migrant birds. Young starlings of supposedly east Baltic origin, kept since July in an outdoor aviary in Wilhelmshaven, showed later in the season a distinct tendency to 'migrate' south-west, that is, in the direction of their presumed origin. This directional tendency was manifest in a round cage of about 2 ft. diameter; it persisted both in conditions which excluded the sight of the horizon and in the presence of great masses of iron, which greatly altered the direction of the compass needle. Orientated flight seemed impossible when the bird could not see the sky, or at least portions of it; but directional flight was observed when a starling was placed in the centre of a hexagonal pavilion, with six windows. When a mirror was attached to every window so that the incident light was deflected by 90° while the direct sky light was shielded off by a blind, the bird's main direction of flight was also deflected by 90° and in the same direction as the light. This type of experiment and similar ones showed that the migrating starling's behaviour was, in fact, governed by the incident light.

Kramer also performed experiments based on direction learning. Twelve equal feeders were placed in a circle around the starling on a movable ring, and covers were mounted on a second ring gliding upon the ring bearing the feeders, giving the experimenter great freedom of action. The food in the feeders was hidden from the birds and could be reached through a slotted rubber membrane. In the absence of landmarks starlings fairly soon learned to visit a feeder in a particular geographical direction, and after a fortnight some birds were perfect. Applying the mirror test as in the migration experiment, such trained starlings were deflected by 90°, thus showing that it was again the incident light which directed the bird. The 'right' feeder was also visited at various hours of the day, thus again showing that the daily movement of the sun was taken into account. On the other hand, it proved very difficult and took a long time to train a bird to keep visiting a feeder which was moved along during the days with the azimuth of the sun. Trained starlings did not perform well under heavily overcast skies, but orientated themselves to artificial light sources in place of the sun. Matthews⁴ has shown that pigeons can not only utilize the azimuth of the sun to get their bearings when returning to their loft from a direction to which they had been trained, but that many of them also return quickly from distant places in various directions. He has put forward a complex hypothesis to explain these results, in which it is assumed that the birds utilize not only the azimuth but also the altitude of the sun for their orientation.

The enumeration of these examples must make it unreasonable to doubt any longer the existence of diurnally changing reference systems for the sun orientation of many animal species. While one might be inclined to favour the simplest hypothesis which

can explain sun navigation, it may in fact be quite complex: there cannot be much doubt that moon-navigation would require very intricate astronomical reference systems; and yet many ornithologists believe in the moon navigation of night migrants, and it has also been fairly convincingly demonstrated for *Talitrus*⁵.

Geographical direction may play some part in the orientation of animals, other than when homing or migrating. Bees in the field, for example, seem acutely aware of the geographical direction; they could be easily trained to visit a dish on a card the western half of which was yellow while the eastern half was blue; they did not visit dishes on cards orientated in the opposite direction, and their visits on the correct cards were independent of the position of the feeding site in the field and of the hour of the day⁶. The well-known straight north-south orientation of the board-like mounds of certain North Australian termites¹¹ (*Hamitermes meridionalis*) may be another example of geographical orientation. While plausible ideas have been developed concerning the advantages of such orientation for the temperature regulation of the mounds, no hypothesis about the orientation of the termites during their building activity could previously be advanced. One now might perhaps assume that these termites also possess a brain mechanism which compensates for the daily movements of the sun.

The brain mechanisms which serve the sun navigation of the animals mentioned are presumably of a similar nature in all species and are probably based on the same principles as human sun orientation. They can also be expected to share certain properties with other time-keeping mechanisms (internal clocks) which are of wide occurrence¹²⁻¹⁴. They keep time fairly well on their own and they are set and kept in pace by light stimuli. Their metabolic nature has in certain cases been established¹⁵. A third property of such systems is that they regulate motor activities. *Drosophila*, for example, normally emerge from their pupae before dawn. If a bottle with larvae and pupae of *D. melanogaster* is artificially illuminated during three consecutive nights and kept in darkness during daytime, the flies which emerge during the following week will 'remember' the time of the artificial dawn and emerge in the evenings, even when now kept in perpetual darkness¹⁶. Examples of this sort could be multiplied; but while they would show that the elements for timing systems in animals very generally exist, they would not greatly add to our understanding of the details of sun navigation. These can only be explored by further experiments.

PHYSICAL INSTABILITY AND THERMAL SHOCK IN RED CELLS

By DR. J. E. LOVELOCK

National Institute for Medical Research, London, N.W.7

THE idea that vital processes might be suspended at low temperatures has inspired attempts to preserve living cells in the frozen state. Success was rare because of the particularly destructive effects of the act of freezing and because it was not realized that each type of cell might require an individual technique of freezing. It was discovered in 1949¹ that the death of spermatozoa on freezing could be avoided if the cells were suspended in a medium containing glycerol, and this removed at one stroke the main barrier opposing the preservation of living cells in the frozen state. Since that time many types of living cell have been preserved successfully for long periods at low temperatures. It is found, however, that living cells do not necessarily survive indefinitely when their temperature is lowered to a level sufficient to reduce biochemical changes to a negligible value. The progressive loss of red blood-cells stored at -78°C . has been reported², and at this temperature also ovarian tissue may fail to survive even one week, although under otherwise similar conditions it survived a year or more at -190°C .³ It has been shown that most of the red blood-cells which do survive storage at -78° are not metabolically aged and behave normally on transfusion⁴.

The damage suffered by red blood-cells during freezing and thawing whether in the presence of glycerol or not is closely correlated with the greatly increased concentration of electrolytes which occurs when water is removed as ice^{5,6}. The exposure to concentrated salt solutions causes first an increase in the permeability of the cell membrane and finally complete dissolution of the cell. This appears to be due to the dispersion of lipids and lipoprotein from the cell membrane under the influence of the solvent action of concentrated salts. Glycerol protects against the immediately destructive action of freezing by reducing the concentration of salts in equilibrium with ice at a given temperature. If the proportion of molecules of glycerol to those of salt is sufficiently high, the concentration of electrolytes never reaches an immediately damaging level during freezing or thawing. The presence of glycerol does not, however, completely prevent the concentration of salts, and cells stored at low temperatures in the presence of glycerol are exposed continuously to relatively concentrated salt solutions. The possibility therefore arose that the observed rapid destruction of red blood-cells by concentrated salt, and the slow deterioration in less concentrated solutions were due to the same process operating at quantitatively different levels. It also seemed possible that the observed improvement in the survival of red blood-cells at 4° and at -20° in media containing sodium citrate instead of sodium chloride was due to the lower solubility of the cell components in sodium citrate. These suggestions have received support from the observation that the survival of red blood-cells in the frozen state is much improved if the salt concentration of the suspending medium is kept as low as possible. This has been done either by increasing the concentration of glycerol^{8,10} or decreasing the concentration of salt¹¹

in the suspending medium before freezing. More direct evidence comes from the chemical analyses of stored cells. Those kept in unfavourable media at temperatures between 0° and -78° are found to have lost considerable quantities of their membrane components.

In the course of experiments designed to determine in greater detail the destructive processes occurring during the storage of red blood-cells at low temperatures, some observations of a more general interest have arisen—in particular, observations relevant to the structure and status of the cell membrane, and to the phenomenon of thermal shock, that is, the destruction of living cells which sometimes occurs on sudden chilling. There follows a preliminary account of these observations.

The experimental investigation of the decay of living cells stored at -78° is necessarily slow. An attempt was therefore made to reproduce these changes above 0° . Red blood-cells were suspended in a medium kept unsaturated with respect to the components of their membranes. This was done either by repeated washing, or by including a neutral absorbent substance such as alumina in the suspending medium.

It was found that lipids and lipoprotein rapidly diffuse from red blood-cells suspended in fresh 0.16 M sodium chloride. After about 3 min. an equilibrium level of these components is reached and the loss from the cell falls to a low value. The equilibrium concentration of lipids and of lipoprotein in the suspending medium did not appear to represent a simple saturation of the medium with these substances. The concentration depended upon the previous treatment of the cells. It increased with the length of time the cells had been stored and decreased with the number of times they had been washed. With fresh cells washed five times in 0.16 M sodium chloride the concentration of lipids in the suspending medium is, normally, cholesterol 22, phospholipid 20, and lipoprotein (N) $18\text{ }\mu\text{gm. per ml.}$ If washing is repeated ten or more times the cells are reduced to a condition similar to that found after prolonged storage at low temperatures. There is loss of components from the cell sufficient to cause a volume reduction of 10–20 per cent. Cells in this condition do not haemolyse more rapidly than fresh cells when suspended in 0.16 M sodium chloride; but if washing is further continued, lipids and lipoprotein are released into the suspending medium only in proportion to the fraction of cells which haemolyse. It is almost as if a proportion of the cells were sacrificed to maintain a necessary minimum concentration of cell components in the suspending medium.

An even more convenient method of investigating the diffusion of components from the red blood-cell is to include a neutral absorbent with their suspension. In practice it is found that a rapid removal of lipids and lipoprotein, and slow progressive lysis take place if cells and chromatographic alumina are suspended together in 0.16 M sodium chloride in the proportion of 1 ml. of cells to 1 gm. of alumina. The results of a typical experiment are shown in Table 1. Using this technique it was possible to investigate the

Table 1. THE LOSS OF COMPONENTS FROM THE HUMAN RED BLOOD-CELL WHEN EXPOSED TO ALUMINA

Conditions	Quantities of membrane components from 1 ml. of red blood-cells remaining after various treatments (units: mgm. and ml.)					
	Cholesterol	Phospholipid	Lipid N	Volume	Hæmoglobin	Dry weight of lipids
Fresh cells	1.21	2.7	0.24	1.0	345	12
After 15 min. with 1 gm. alumina per ml. of cells at 37°	1.09	2.15	0.15	0.75	340	7
After 1 hr. at 37° in plasma	1.13	2.90	0.15	0.75	340	7
Lost from cells	0.12	0.55	0.09	0.25	5	5
Recovered from alumina	0.12	0.80	0.08	—	0	4.5

diffusion of various cell components and the rate of hemolysis of the cells, at different temperatures. It was found that between 40° and 5° the rate of hemolysis of cells in the presence of alumina decreased in a manner suggestive of a process governed by simple diffusion, that is, with an activation energy of 5,500 calories. At 4° the rate of hemolysis began to increase as the temperature was further lowered, and at the lowest temperature so far investigated, -5°, was still increasing. There was also, at temperatures below 4°, a decrease in the rate of diffusion of cholesterol and phospholipid from the cell. These results suggest a change in the state of the cell membrane at 4°. In this connexion it is particularly interesting to note that 4° is usually recommended as a better temperature for the routine storage of red blood-cells than 0°¹³. Another point of interest is that the effects of alumina, like those of washing, are strongly influenced by the past history of the cells. Cells stored ten days in 'acid citrate dextrose' plasma at +4° hemolyse in the presence of alumina twice as quickly as fresh cells.

Unlike the diffusion of superficial protein from the red blood-cell¹³, the loss of lipoprotein does not appear to be simply reversible. Cells which have lost 40 per cent of their lipoprotein and 25 per cent of their volume are still in this condition after storing for one hour at 37° in a large volume of fresh plasma. On the other hand, P. L. Mollison, in a personal communication, reports that cells which have been washed seven times, and also a considerable proportion of cells withered by storage for long periods at low temperatures, survive normally on transfusion.

It is well recognized that the fluid contents of living cells are maintained at their normal levels by active processes against loss by diffusion. It is also recognized that damage can result at low temperatures from the greater reduction of metabolic activity as compared with diffusion¹⁴. The ability of

the normal red blood-cell to synthesize cholesterol¹⁵ and other membrane components¹⁶ has been shown. This, together with the evidence above, suggests that not only the fluid contents but also the structure of the red blood-cell is maintained by a combination of synthesis and of passive diffusion from the plasma. So far as the red blood-cell is concerned, in the lease of life the tenant is responsible not only for interior decoration but also for structural repairs. The failure of the repair processes appears to be the first cause of death of red blood-cells during cold-storage in their normal medium.

It is important to note that the death of red blood-cells stored in plasma containing sodium citrate (acid citrate dextrose) at +4° and also possibly in an equivalent medium with glycerol at -22°¹⁷ does not appear to be due to physical dissolution. Cells stored under these conditions do not, while alive, lose their membrane components, and those which survive do not live as long as normal cells when transfused. Thus, the physical breakdown of cells which occurs during cold storage in their normal media can be avoided by a suitable choice of storage conditions, at least until death occurs from other causes. The most suitable media for the storage of red blood-cells seem to be those in which the solubility of the cell components is least: namely, slightly acid media containing a salt, such as sodium citrate or acetate, the anion of which is more hydrated than the chloride ion.

Thermal Shock

The loss of lipids in an indiscriminating manner by simple diffusion appears to cause no great harm to the red blood-cell. In contrast, the loss of phospholipid selectively renders the cell metastable and subject to rapid lysis on cooling below 20°. The selective removal of phospholipid can be achieved practically by three methods. First, as is well

Table 2. THE LOSS OF COMPONENTS FROM HUMAN RED BLOOD-CELLS FOLLOWING THE VARIOUS TREATMENTS DISCUSSED IN THE TEXT

Treatment or storage conditions	Loss of cell components (per cent)					
	Cholesterol	Phospholipid	Lipid N	Volume	Hæmoglobin	
10 days at 0° in 0.16 M NaCl + 0.2 per cent glucose buffered to pH 7.0	23	22	46	—	5.0	Unfavourable storage conditions
14 weeks at -22° in 0.11 M sodium citrate + unbuffered 30 per cent glycerol	23	27	51	40	2.6	
1 year at -78° in 0.16 M NaCl + 16 per cent glycerol	17	22	29	20	6.0	
10 days at 0° in 'A.O.D.' plasma	5	7	0	0	1.0	Favourable storage conditions
14 weeks at -22° in 'A.O.D.' plasma + 30 per cent glycerol	0	0	0	0	1.8	
15 min. at 37° with 500 mgm. alumina per ml. of cells	14	16	36	17	1.0	Simulated unfavourable storage
20 washings at 37° in 0.16 M NaCl + 0.2 per cent glucose	15	15	29	13	2.7	
1 hr. at 0° in 0.03 M NaCl	9	26	12	—	1.7	Conditions causing sensitivity to thermal shock
1 hr. at 37° in 0.16 M NaCl containing 5.0 mgm. per ml. of detergent D ₁₁	10	22	18	—	0.3	

known¹⁸, by treatment with bacterial toxins, in particular, the toxin of *Cl. welchii*; secondly, by exposure to 1.0 M sodium chloride¹⁹; and thirdly, by means of selective absorbing substances, for example, certain anti-tubercular, macro-molecular detergents¹⁹. The effect of one of these substances, prepared by condensing *p*-tert-octyl-phenol formaldehyde resin with ethylene oxide, is shown in Table 2.

Some other living cells in their normal state show a similar sensitivity to cooling. This was first investigated with mammalian spermatozoa²⁰, and is usually referred to as thermal shock. An excellent review of this effect, which is found with a wide variety of living cells, has recently been written²¹. There is a considerable body of evidence to suggest that the lysis of red blood-cells which have lost some of their phospholipid, and the destruction of normal living cells by sudden cooling, are manifestations of the same general phenomenon. Thus, thermal shock with mammalian spermatozoa is reduced by treating the cells with lecithin before cooling²². It is increased if the cells are treated with the α toxin of *Cl. welchii* or with the macro-molecular detergent described earlier. Conversely, red blood-cells which have been denuded of phospholipid can be protected against thermal shock if they are suspended in a medium containing lecithin.

The destructive effects of thermal shock take place with great rapidity. Red blood-cells rendered sensitive to thermal shock hemolyse within 30 sec. if suddenly cooled from 37° to 0°. If they are returned to 37° after spending only one second at 0° they hemolyse just as rapidly. Thus, the destructive effect of cooling takes place within one second, and may well be faster even than this.

The physical factors which appear to be important in the production of thermal shock are the temperature of the cell and change of temperature to which it is subjected. The rate of change of temperature if faster than 0.1 deg. per sec. and the gradient of temperature across the cell are relatively unimportant. The effect can occur at temperatures as low as -30°²¹. There is therefore considerable circumstantial evidence to suggest that the effect results from some physical change in the cell membrane at low temperatures.

The change in the chemical structure of the cell which confers sensitivity to thermal shock appears to be an increase in the ratio of cholesterol, or possibly the cholesterol lipoprotein complex, to lecithin in the cell membrane. The alteration of this ratio either by removing lecithin or by adding cholesterol increases the sensitivity to thermal shock. The absolute amounts of these lipids are relatively unimportant.

The observations upon the breakdown of red blood-cells by diffusion and by thermal shock provide some evidence concerning the status of the components of the cell membrane. They suggest that some of the phospholipid and cholesterol of the cell are free to diffuse reversibly, and that lipoprotein is free to diffuse away from the cell but does not return by the same route.

The classical view of the structure of the red blood-cell membrane implies a framework of stroma surrounded by a bimolecular layer of lipids, with a sprinkling of antigenic and antisphering protein at the surface. It seems unlikely that a cell possessing such a structure could lose a substantial portion of its membrane components and yet remain intact. Among more recent views upon the architecture of

human red blood-cells are two which agree quite well with the experimental results outlined above. The first²³ suggests a membrane composed of lipoprotein the concentration and orientation of which diminish radially inwards. The second²⁴ envisages a membrane composed principally of fibrils, of a lipoprotein called elinin arranged parallel to the cell surface and cemented together by ether-soluble lipids. The idea that the lipoprotein of the cell membrane is held at a preferred orientation fits harmoniously with the observed irreversible nature of its diffusion. If the cell membrane is relatively thick, as recently proposed²⁵, some loss of its components could presumably be borne without the destruction of its function as a permeability barrier. The observed volume changes are also in good agreement with those of a hypothetical cell with a thick membrane composed of a 2 per cent lipoprotein gel.

The orientated lipoprotein of the cell membrane is thought to be cemented together by ether-soluble lipids²⁴. If this hypothesis is accepted, it provides grounds for an attractive speculation concerning the mechanism of thermal shock. If the cement is made from a mixture rich in cholesterol, it is likely to be brittle at low temperatures. The mechanical stresses resulting from a change in temperature could then cause the cement to fracture, and destroy the permeability properties of the membrane. Whatever is the true function of the various components of the cell membrane, the physical factors upon which thermal shock is observed to depend make it probable that the phenomenon depends upon some mechanical failure at least similar to that suggested.

The experimental results reported in this paper form the subject of a more detailed account which will be published later.

I am indebted to Dr. A. S. Parkes for his interest and advice. My thanks are also due to Dr. P. L. Mollison for making freely available the results of his investigations, and for supplying samples of frozen and stored blood. I also wish to acknowledge the skilful assistance of Miss G. O. McMahon.

OBITUARY

Sir John Myres, O.B.E., F.B.A.

SIR JOHN MYRES, emeritus professor of ancient history in the University of Oxford, died peacefully on March 6, at his home in Oxford, aged eighty-four. The world of scholarship and his many friends will feel a grievous sense of loss.

Few, if any, in the past half-century strove more devotedly and clear-sightedly than he in the allied fields of archaeology and anthropology, not only in a great output of influential books and articles, but also in vigorous executive action. As a geologist and a geographer, too, he held an honoured place. His broad humanism, capacity for intensely hard work, and expressive prose style which clarified difficult subjects with wit as well as wisdom, were the inheritance from the confident, all-inquiring era of the later nineteenth century. The bold sweep of such wide humanism, unafraid of the great problems which humanity has to face, but not pedantic, without dogmatic ideology, and founded firmly on fact, is more needed to-day than ever.

A scholar of Winchester and of New College, Oxford, his gifted versatility was evident from the start. In 1892 he won a Craven fellowship for classical studies in Greece, and also the Burdett-Coutts scholarship in geology. It is not possible to enumerate all the distinctions which followed throughout a long life, lived to the last with outstanding energy, courage and cheerfulness. He was a Student of Christ Church during 1895-1907, and then was elected professor of Greek in the University of Liverpool. In 1910 he returned to Oxford as Wykeham professor of ancient history, and held the chair until 1939. During 1919-32 he was general secretary of the British Association, a vice-president of the Society of Antiquaries from 1924 until 1927 and gold medallist in 1942, a past-president of the Royal Anthropological Institute, Victoria medallist of the Royal Geographical Society and chairman of the British School at Athens during 1934-37. He was honoured by doctorates from the

Universities of Wales, Manchester, the Witwatersrand and Athens.

His adventurous career as a lieutenant-commander and later commander (R.N.V.R.) in the Aegean during the First World War has an almost legendary fame, in the Minoan and Homeric tradition. For his exploits, notably against the Turkish coastal garrisons, he was made a Commander of the Royal Order of George I of Greece. He received his knighthood in 1943.

Where others would have relaxed their efforts, Sir John Myres redoubled his. The last three books he wrote, "Scripta Minoa II", "Geographical History in Greek Lands" and "Herodotus: Father of History", all appeared after his eightieth birthday (which had been celebrated by a special number of the journal *Man*).

Methods and aims in education in schools and universities interested him greatly, and his combination of imagination with shrewd common sense gave his colleagues many a lead to follow. His practical qualities shone in administration, and to him goes a large measure of the credit for initiating International Congresses in Prehistoric and in Anthropological Studies, which now meet at regular intervals.

His aim was to encourage people to think for themselves, and think clearly. His personal preference was for difficult problems which went to the heart of human history and action, as shown in his famous volume "Who Were the Greeks?". But it was perhaps in personal contacts that he exerted his greatest influence. He was always accessible, helpful, frank; and especially ready to encourage young men. To visit him and discuss one's work was inspiring, for he had a truly noble mind, and one never departed without several valuable new ideas that had been good-naturedly suggested.

Those who had the privilege of knowing him—and they are scattered all over the world—understood how greatly he was sustained, especially in the infirmities of his later years, by the devoted care of Lady Myres. His surviving son, Mr. J. N. L. Myres, is Bodley's Librarian.

JOHN BRADFORD

NEWS and VIEWS

Agriculture In Great Britain:

Sir James Scott Watson

SIR JAMES SCOTT WATSON, chief scientific and agricultural adviser to the Ministry of Agriculture and director general of the National Agricultural Advisory Service, is retiring on December 31 next, shortly after his sixty-fifth birthday. After graduation at Edinburgh and advanced study in Berlin and at the Iowa State College, he joined the agricultural staff at his old University. During the First World War he served with the Royal Field Artillery in France. During 1922-25 he was professor of agriculture and rural economy at Edinburgh, going thence to the Sibthorpe chair of rural economy at Oxford, which he occupied until 1944. The Second World War took him away from academic life, his important duties including membership of the Scientific Food Committee and during 1942-44 the post of agricultural attaché at the British Embassy, Washington. Returning, he became chief education and advisory officer in the Ministry of Agriculture, and in 1948 moved to the post he is about to relin-

quish. Sir James's exceptionally wide and profound range of agricultural knowledge in the detail of practice, in the applications of science, in history and in national economic aspects, have made him for many years an outstanding authority. His ease and clarity as a writer have enriched the literature with many papers and some excellent books including the famous "Agriculture: the Science and Practice of British Farming", everywhere known as "Watson and More". Broadcast talks, lectures and official work have made him widely known and greatly respected among farmers, and his editorship of the *Journal of the Royal Agricultural Society* from 1931 until 1945 widened still further his influence on agricultural teaching and thought. To him, as its first head, fell the launching of the National Agricultural Advisory Service, instituted in 1946. He is a member of the Agricultural Research Council and was knighted in 1949.

Prof. H. G. Sanders

PROF. H. G. SANDERS, who is to succeed Sir James Scott Watson as chief agricultural and scientific

adviser to the Ministry of Agriculture, was born in 1898 and is at present professor of agriculture at Reading. From Wellingborough School he joined the Royal Field Artillery in 1917, served in France and on demobilization went up to St. John's College, Cambridge, where he studied agriculture. Interest in experimental husbandry drew him away after a short spell of practical farming, and during 1922-29 he was on the staff of the Animal Nutrition Institute (then in Cambridge) engaged on statistical analyses of lactation phenomena and other cattle physiology topics. Turning then, with great success, to the teaching of crop husbandry, he became a University lecturer in the School of Agriculture, Cambridge, filling that position until 1944, when he was elected to the professorship at Reading. In fruitful partnership with Mr. F. H. Garner, he completed well-known field-experiments on plant populations and yield in potatoes, cereals and sugar beet, on cultivations and in the then novel use of grass and lucerne mixtures. He was elected to a fellowship at St. John's in 1944 and in 1939 published "An Outline of Crop Husbandry", still a standard text. As executive officer of the Hertfordshire War Agricultural Executive Committee, 1941-44, he achieved notable success in the stiff war-time tasks of the county. In the Agricultural Improvement Council of England and Wales he has played a leading part in developing the regional husbandry experimental farms supported by the Ministry. He is a member of the University Grants Committee. Both academic and farming circles will welcome the appointment.

Pathology at Sheffield: Dr. D. H. Collins, O.B.E.

DR. D. H. COLLINS, reader in clinical pathology in the University of Leeds, has been appointed to the chair of pathology in the University of Sheffield in succession to Prof. H. N. Green, who has taken up the chair of experimental pathology in the University of Leeds (see *Nature*, December 5, p. 1028). Dr. Collins was educated at Rossall School and the University of Liverpool, where he graduated in medicine in 1930, taking his M.D. three years later. In 1934, after various hospital and university appointments in Liverpool, he became the first Rheumatism Research Fellow in the University of Leeds and held this fellowship until the outbreak of the Second World War, when for the next seven years he was seconded to the Emergency Pathological Service. After establishing a base-hospital laboratory at Scotton Banks Sanatorium, Dr. Collins went to Sheffield in May 1940 as pathologist to Wharfedale Emergency Hospital, later becoming medical superintendent of the Hospital in charge both of its pathological services and its medical administration. In October 1946 he returned to the University of Leeds as reader in clinical pathology. Apart from his work on a number of medical advisory committees and being an assistant editor of the *Journal of Pathology and Bacteriology*, Dr. Collins's main research interests are centred on disease of the bone, and he is the author of the book "The Pathology of Articular and Spinal Diseases".

Civil Engineering at University College, Swansea:

Dr. B. G. Neal

CONSIDERABLE developments have taken place during recent years in the School of Engineering at Swansea under the direction of Prof. L. J. Kastner. Opportunity has now been taken to institute a chair in civil engineering, and the first professor of this

subject will be Dr. B. G. Neal, who will take up his appointment on October 1 next. Dr. Neal obtained first-class honours in the Mechanical Science Tripos at Cambridge in 1942, being awarded the Rex Moir, Ricardo and John Bernard Selly Prizes. For the next three years, as a temporary experimental officer, he was concerned with naval aircraft work, and in 1945 represented the Department of Scientific and Industrial Research at the Underwater Ballistics Conference in Washington. A later period in the United States was spent on research on plastic theory at Brown University, R.I., under Prof. W. Prager. Apart from this, his research work has been at Cambridge, where he is a Fellow of Trinity Hall and lecturer in engineering. A paper on the lateral instability of yielded mild steel beams was published by the Royal Society. Publications on framed structures under repeated loading gained for Dr. Neal and his collaborator the Manby Premium and the Telford Premium of the Institution of Civil Engineers, and he is at present completing a book on analytical methods of plastic theory.

Abbreviation of Bacterial Generic Names

WHEN using the binomial system of nomenclature, bacteriologists often contract or abbreviate the generic name; there are no rules to guide them, and each author may create his own shortened form. What form appears in print depends on the editorial policy of the particular journal, and in this there does not seem to be a common practice. The abbreviations used in the "World List of Scientific Periodicals" are based on the general and special rules of the International Code of Abbreviations for Titles of Periodicals, but similar rules do not exist for the generic names of bacteria. The Bacteriological Code of Nomenclature does not recognize the abbreviation of generic names, which seems to be a labour- or space-saving device resorted to by authors and editors. A preliminary inquiry is being made to find out if there is a demand from editors for the standardization of these abbreviations, and it is hoped to collect information on the present policy of certain journals published in the English language, some of which use single-letter abbreviations and others use rather longer forms. The inquiry was started in relation to the abbreviation of generic names of bacteria, but other points have been raised by individual editors. Those who hold views on this and related subjects are asked to get in touch with Dr. S. T. Cowan, the joint secretary (representing medical bacteriology) of the International Committee on Bacteriological Nomenclature, at the National Collection of Type Cultures, Colindale Avenue, London, N.W.9.

Figuring of Types in Entomology

At a meeting of the International Union of Biological Sciences, held at Nice during August 1953, a type-figuring sub-section of the Entomology Section was formed, and its activities are now directed by a committee of fifteen under the chairmanship of Mr. N. D. Riley, keeper in the Department of Entomology, British Museum (Natural History), London. The objective of the sub-section is to make as readily available as possible information on types of insects and other animals, especially by distributing figures of the type specimens, to assist in research work and to have some information available in case types are accidentally destroyed. It is proposed to collect in a central file negatives of photographs of type speci-

mens, or of photographs of drawings or other illustrations of type specimens or of their parts; to catalogue these and make lists available from time to time; to make and to distribute prints of the photographs for suitable fees to those requesting them; and, when finances permit, to make or arrange to have made illustrations of types for the central file. The sub-section is run on a non-profit basis, and in fact will operate at a financial loss until receipts from the sale of prints cover expenses or until grants are obtained. The chief need at the moment is for negatives or other illustrations for the central file, unpublished illustrations being, of course, the most desirable. At present the headquarters of the sub-section and the central file are in Ottawa, and all correspondence should be addressed to Mr. P. F. Bruggemann, Curator, c/o Division of Entomology, Science Service Building, Ottawa, Ontario.

A Faked Fossil

IN the *Museums Journal*, March 1954, Mr. H. F. Whitworth, of the Geological and Mining Museum, Sydney, exposes the faked nature of an insect wing in a specimen of selenite. Presented to the Museum in 1912, this was examined by Dr. R. J. Tillyard, who with some hesitation was eventually convinced of the genuineness of the 'fossil' and stated that it belonged to the Tertiary age and was unlike any living form. He placed it within the family Tettigoniidae and named it *Austrodictya corbouldi*. Recently, the specimen has been re-examined and it was seen that the crystal of selenite has been opened by a knife, the wing inserted and the edge of the crystal pounded in an endeavour to hide the crack produced. Experiments showed that the flexible nature of selenite allowed this operation to be carried out easily. The wing has now been identified as the forewing of *Terpandrus horridus*, a present-day form, commonly known as the great gum-tree grasshopper.

Latin American Research in Parasitology

THE third report in the series, "Latin American Contributions to Scientific Progress", is entitled "Parasitology 1949-50" (pp. 287; Montevideo: Unesco Science Co-operation Office for Latin America, 1953), the two previous publications being concerned with chemistry and with mathematics, respectively. The object of the series is to make known to a much wider public than at present the contributions that Latin American scientific workers are making in various fields. The present report, which is by Prof. J. E. Mackinnon, in collaboration with Prof. S. B. Pessoa, Prof. F. Pifano and Dr. A. Trejos, is concerned with the publications in the field of parasitology that appeared during the years 1949-50. Parasitology is a field that has close association with other studies such as pathology, hygiene, etc.; but while clinical and surgical references appear in the bibliography, the reviews themselves are concerned almost exclusively with experimental and descriptive parasitology, although a certain amount of attention is given to epidemiology and prophylaxis since they are closely related to the biology of the parasite. The reviews are divided into a series of chapters under the five headings protozoa, helminths, arthropods, fungi and various, occupying pp. 14-250, and the bibliography occupies the remaining thirty-seven pages. There are about eleven hundred references, and from this bibliography the titles of the publications, the names of the workers and their fields of study can be found, all of which is most useful information. The authors

are Latin Americans or come from other countries but live and work in institutions in Latin America. Naturally, some publications of importance to Latin America come from European possessions or from Panama, and these have been dealt with in their appropriate places by footnotes and do not appear in the body of the text or in the bibliography. On the whole, the English is good; but there are some slips: for example, "flies" as the plural of fly, "on account of" instead of "as shown by" and so on.

Diploma in Health Education

ONE of the greatest handicaps to health education has been the lack of properly qualified people. It is hoped that this weakness will be remedied by the proposal of the Institute of Education (University of London) to offer a comprehensive course in health education. It is intended to give a professional training to doctors, nurses, teachers and others with suitable experience, in the basic disciplines and practice of health education. The course will last a year and lead to a diploma of the Institute. The syllabus will deal with the principles of education; principles of social and preventive medicine, including epidemiology and vital statistics; the history and administration of public health and of education; the scientific bases of health and human behaviour with particular emphasis on heredity and genetics, growth and development, environmental hygiene, and the general principles of the causation, spread and prevention of infective disease; and the principles, methods and media of health education. Field-work will form a part of the course and visits will be made to illustrate the work of hospitals, clinics, local health authorities, schools, youth clubs and industrial concerns.

From the content of the course it would seem that students who obtain the diploma will be qualified to plan and administer comprehensive health education programmes, as well as having the practical experience of the health teacher. A feature of particular interest is the opportunity of providing a tailor-made syllabus for each student to ensure that those with a medical background devote more time to studying education, and vice versa. Sponsors of the course are the London School of Hygiene and Tropical Medicine, the Institute of Child Health and the Central Council for Health Education.

Auxin and Mushroom Growth

I. M. FRASER (*Austral. J. Biol. Sci.*, 6, 379; 1953) reports that the cultivated mushroom, *Pleurotus hortensis*, var. *albida*, was unable to grow appreciably on a liquid medium containing only glucose, asparagine and mineral salts. Growth was slightly increased by additions of thiamin and biotin to this medium; but a number of other vitamins were without effect. Indole-3-acetic acid, however, in concentrations of 5-100 mgm./l., produced a very notable increase in growth, particularly with biotin and thiamin present, but only in surface culture. The growth of both floating and submerged inocula was markedly increased by additions of yeast extract, cotton wool extract, or mushroom compost extract, although these did not appear to contain appreciable quantities of indole-3-acetic acid. The fungus grew fairly well on basal medium solidified with agar which had been purified to remove vitamins. Addition of thiamin or biotin did not promote growth. Concentrations of indole-3-acetic acid of 10 and 100 mgm./l. almost completely prevented initial growth,

while concentrations of 0.001, 0.1 and 1.0 mgm./l. were without effect. However, after about thirty days, vigorous growth commenced in the medium originally containing 10 mgm./l. indole-3-acetic acid and proceeded at the same rate as in its absence. It seems probable that this was due to inactivation of the indole-3-acetic acid by the small amount of mycelium formed. It is suggested that indole-3-acetic acid may play a part in the growth processes of this fungus similar to that in higher plants, although the possibility that some related substance such as tryptophan is required for growth must also be considered, particularly in view of the unidentified growth-promoting factor present in various extracts.

Dissemination of Rust Fungi in India

In Scientific Monograph No. 18, published in 1952 by the Indian Council for Agricultural Research, Prof. Mehta, of Agra College, has presented a detailed account of a study of the dissemination in India of three rusts of wheat and barley, *Puccinia graminis tritici*, *P. triticea* and *P. glumarum*. The work was carried out mainly between the years 1932 and 1938 and is a continuation of that reported earlier in Monograph No. 14. By means of slide traps on stationary aeroscopes or on kites, balloons or aeroplanes in the vicinity of some twenty stations throughout the country, Prof. Mehta has compiled estimates of the aerial distribution of the fungi and related these data to the trajectories of relevant winds and the incidence of disease outbreaks. The results, presented as a series of maps and tables in the monograph, showed that spore showers preceded outbreaks of rust at most stations and that winds usually came from places where the diseases had been prevalent from fifteen days to two months previously. Such sources of inoculum usually originated in the hills, where an early crop was sometimes grown or developed from tillers or self-sown plants, becoming infected earlier than that in the plains. These findings are discussed and the conclusion reached that the most important foci for the dissemination of rust inoculum lie in central Nepal, the Nilgiris and the Palni hills, and that early spread from these regions to the Indo-Gangetic plain and Peninsular India, respectively, is chiefly responsible for outbreaks experienced there. In a final section the author briefly reviews the situation and makes proposals for the control of these rusts in India. Measures recommended for specified hill regions include suspension of the early crops of wheat and barley, destruction of self-sown plants and stray tillers between seasons and postponement of sowing to coincide with that in the plains.

Graphs of the Compton Energy-Angle and the Klein-Nishina Formula

CIRCULAR 542 of the National Bureau of Standards, Washington, D.C., is primarily a representation in graphical form, by Ann T. Nelms, of the Compton energy-angle relationship and the differential and integral Klein-Nishina cross-sections as functions of the energy and direction of the scattered photon and of the recoil electron (pp. iv + 89. Washington: Government Printing Office, 1953; 55 cents). Unpolarized primary gamma-rays in the energy-range 10 keV.-500 MeV. are considered. It is stated that interpolated values may be obtained from the curves with an accuracy of 2 per cent. The data are expressed in the units used most often by experimentalists and are based on DuMond and Cohen's (1951) values of

the fundamental constants. The graphs are preceded by a discussion of the various experimental, theoretical and mathematical considerations involved in the relationships finally chosen for computation and representation. The Circular represents the fourth item in a series of surveys and tabulation of information on radiation physics carried out with the support of the Biophysics Branch of the United States Atomic Energy Commission. The three previous items have been given limited circulation.

Webster Plass Collection of African Art

THE late Mr. Webster Plass, of Philadelphia, and his wife collected for many years examples of African works of art. Mr. Plass always wished that his collection would eventually find a permanent home in the British Museum, and Mr. William Fagg, assistant keeper in the Department of Ethnography, has now compiled a memorial catalogue of the collection. Bearing the title "Webster Plass Collection of African Art" and the sub-title "Catalogue of a Memorial Exhibition held in the King Edward VII Galleries of the British Museum", this catalogue has been published by the British Museum, the cost having been borne by Mrs. Plass (pp. 47 + 48 plates; 1953). There are forty-six pages of illustrations of works of art made by various Central and West African peoples, and these are described in detail in the catalogue. There is also a map showing the distribution of their makers. The whole is well and clearly set out, and Mr. Fagg is to be congratulated on his work. It is a pity, perhaps, that the paper on which the half-tones are printed could not have been of a rather better quality. The reproductions are good but could have been even better. There is a short introduction on African art in general.

Stanford University Natural History Museum

THE main fish and herpetological collection rooms of the Natural History Museum of Stanford University have recently been entirely refitted at a total cost of 30,000 dollars, 93 per cent being raised by a graduate students' Zoology Project Fund to which many graduates and friends of the University have contributed. The fish collections have been supplied with 9,000 sq. ft. of new steel shelving which will increase the fish research space by two-thirds. Modern lighting has been installed and also a new electric 'dumb waiter' to connect the double-decked fish collection with other floors in the building, so that the Stanford collection, which contains about 750,000 specimens, is now one of the best-housed in the world. It has also been possible to utilize the old shelving for renovating the herpetological collection facilities, thus increasing their shelf-space by 100 per cent.

Industrial Relations and Human Relations

IN an address on January 20, 1954, to the Birmingham branch of the Institute of Personnel Management, Sir Godfrey Ince, permanent secretary to the Ministry of Labour and National Service, concluded that although we have gone a long way towards establishing good industrial relations and constitutionalism in British industry and have made great progress in good labour relations techniques, "we have not yet gone very far in tackling the problem underlying good human relations, the problem of securing the right attitude of mind in industry". The address is printed in the latest issue of the Institute's journal, which also contains an important article on joint

consultation in the electricity supply industry by R. D. V. Roberts, secretary to the National Joint Advisory Council for the Electricity Supply Industry (36, No. 327; March 1954). A report of a discussion on the value of wages as an incentive to higher production is also included.

The National Trust

THE fifty-eighth annual report of the National Trust, for the year 1952-53, gives a further warning of the importance of increased voluntary support to enable the Trust to take advantage of the new opportunities which the Historic Buildings and Ancient Monuments Act offers it. This Act embodies a good many suggestions made to the Government by the Trust, and the Council notes with particular satisfaction that the Act not only allows grants to be made from the Land Fund to acquire historic buildings but also permits annual grants for maintenance, including assistance in the case of inhabited houses in private ownership. Although the deficit of the Trust on maintenance and administration in 1952 was no more than £29,000 on an income of £355,000, and its membership rose during the year from 23,365 to 40,300, the Jubilee Fund raised in 1947 is now exhausted as well as most of the special reserves; it has been necessary to impose a temporary standstill on all but essential improvements, and only the most urgent repairs and decorations can be carried out from general funds. This naturally limits the properties which the Trust is able to accept for preservation, in the absence of provision for endowment; and a large increase in the subscription income is desirable if the Trust is to continue to carry on and expand its work.

Progress

AN excellent example of the magazines which are being produced by the larger industrial undertakings both for the information of their own employees and the enlightenment of others is shown by the present issue of *Progress*, the journal of Unilever, Ltd. (43, No. 241; 1953-54). Prof. G. J. Renier contributes a factually imaginative discourse on Anglo-Dutch amity (Unilever has strong Dutch associations), while other articles deal with places important in the Unilever economy, like the Belgian Congo and other parts of West Africa. A fascinating and unusual article on trade marks and their protection is contributed by L. A. Elwood, while other articles deal with such topics as colour in the factory and recent developments in industrial welfare in Norway. Ronald Brech explains as lucidly as possible the meaning and purpose of the bank rate, and Dr. Eric Ashby describes the need for co-operation between the universities and industry in the selection and training of potential managerial recruits. The final article shows the way in which the Department of Scientific and Industrial Research serves the community not merely through industry but more directly as a source of knowledge to make more widely known the decisions of government. The journal is produced in exquisite taste, the cover being made up of two water colours by the Belgian artist, Prof. Maurice Van Esche, who is said to be one of the few European painters who have understood and been able to interpret the character of Africa.

Manchester Public Libraries: Report for 1952-53

THE report of the City of Manchester Public Libraries Committee for the year 1952-53 (pp. 36+

8 plates) records an increase in total issues to readers from 5,937,230 to 6,241,375. This was due partly to the opening in May 1952 of the first specially designed library in Wythenshawe, already the third busiest library in the city. Of this figure, as the City Librarian notes in his report, 1,003,644 issues were to children, but books consulted in the reference libraries also increased, from 676,469 to 719,361, with an increase in readers from 555,455 to 602,528. The number of volumes in the reference libraries increased from 418,328 in 1952 to 425,484 in 1953; of these, 55,777 volumes were in the technical library, compared with 54,100. Additions to the stock of the libraries totalled 83,727, withdrawals amounting to 80,554, and the City Librarian directs attention to the effect of the increasing cost of books: while for the three years 1948-49, 1951-52 and 1952-53 the numbers of volumes purchased were respectively 92,466, 93,593 and 80,522, there being a noticeable reduction in the most recent figure, the corresponding expenditure has been £31,898, £36,331 and £36,693, the average price per book being respectively 6.80s., 7.78s. and 9.11s. Moreover, in the Reference Library the average cost is now 28.49s. and in the Technical Library 29.18s. While the book fund has slightly increased, the newspapers and periodicals fund has lagged much further behind rising costs; in 1952 this amounted to no more than £2,899, an increase of £55 since 1921, and, of fifty-eight titles of science periodicals listed by the Science Museum Library in London as not available for loan to other libraries, only eighteen were available in the Manchester Public Libraries. These rising costs obviously hamper the extension of the Technical Library service, and hope is expressed that speedy government aid will be forthcoming: "for it is within the power of the public library service of this country to provide industry with an information service which would repay handsomely any expenditure involved". During April 1952 the department acquired an 'Agoflex' copying machine which renders possible a 'while-you-wait' copying service: 5,675 items have been copied in this way, compared with 2,089 last year. Some 503 books and periodicals were loaned specially to local firms, an increase of 40 per cent on the previous year, and stress is laid on the growth of co-operation with the industrial libraries of the area, the library of the Manchester College of Technology and other local and national libraries.

New Laboratory for Oceanographic Research at Woods Hole

THE United States Navy has built a new laboratory for oceanographic research at Woods Hole, Massachusetts, and the laboratory will be formally opened on June 21. Following this, during June 22-24, the United States Office of Naval Research, in conjunction with the National Academy of Sciences and the National Research Council, will hold a three-day oceanographic convocation, in which will be presented the broad scientific significance of oceanography, its needs and its potentialities, and its relations to the constituent fields of science. The first day will be devoted to physical oceanography, the second to biology in oceanography and the third to geology, geophysics and meteorology in oceanography. Some twenty scientific workers, drawn from both the United States and abroad and representing a wide field of interests, are being invited to participate. The proceedings will afterwards be published.

Pan Indian Ocean Science Association : Congress In Perth, Western Australia

THE second science congress of the Pan Indian Ocean Science Association will be held in Perth in the University of Western Australia during August 17-24, under the presidency of Prof. H. J. Bhabha. The Association, which was formed in January 1951 at a meeting in Bangalore, exists to discuss and promote concerted action in regard to scientific problems affecting the peoples and countries around the Indian Ocean and generally to improve friendship and co-operation among them. Representatives are sent from Australia, Burma, Ceylon, France, India, Madagascar, Malaya, Netherlands and Portugal. Those attending the congress will be in one of three categories: official delegates of each participating country, the limit being ten per country; accredited members, who are nominated by the representative institution of the member country; and guests invited by the president. The work of the congress will be for the most part arranged by the seven sections of the Association: (A) physical sciences; (B) biological sciences; (C) geological sciences; (D) agricultural sciences; (E), economics, education and social sciences; (F) geography and oceanography; and (G) human ecology. During August 25-28 a number of excursions will be made, catering mainly for those concerned with the biological sciences; geology and mining; and agricultural sciences and forestry. All communications relating to the congress should be addressed to Prof. A. D. Ross, Honorary Secretary, P.I.O.S.A., 31 Ventnor Avenue, West Perth, Western Australia.

Vacuum Techniques : Symposium In the United States

A SYMPOSIUM on high vacuum, organized by the Committee on Vacuum Techniques, will be held at the Berkeley Cartaret Hotel, Asbury Park, New Jersey, during June 16-18, 1954. The papers to be read will deal with the following five topics: a panel on nomenclature and standards; new equipment and instruments; fundamental developments in vacuum technology; methods and techniques; and applications and processes. The Committee on Vacuum Techniques has been organized as a non-profit corporation, with the prime purpose of sponsoring the symposium; in addition, it hopes to further the dissemination of knowledge of high vacuum techniques and to assist in the establishment of universally acceptable nomenclature and standards. All individuals and companies interested in attending the symposium, presenting papers or participating in other activities of the Committee should write to the Committee at P.O. Box 1282, Boston, Mass.

Chemical Society : Officers

OFFICERS of the Chemical Society have been elected as follows: *President*, Prof. W. Wardlaw; *Vice-Presidents*, Sir Ian Heilbron, Sir Cyril Hinshelwood, Prof. C. K. Ingold, Dr. W. H. Mills, Sir Eric Rideal, Sir Robert Robinson, Prof. R. D. Haworth, Prof. E. L. Hirst, Prof. E. R. H. Jones, Prof. R. P. Linstead, Prof. W. H. Melville and Sir John Simonson; *Treasurer*, Mr. M. W. Perrin; *Secretaries*, Prof. H. Burton, Prof. E. D. Hughes and Dr. L. E. Sutton; *New Members of Council*, Dr. C. C. Addison, Dr. V. C. Barry, Dr. E. J. Bourne, Dr. E. A. Braude, Dr. H. M. N. H. Irving, Prof. J. M. Robertson, Prof. H. N. Rydén and Prof. H. D. Springall.

Announcements

PROF. T. H. MARSHALL, professor of social institutions in the London School of Economics and Political Science, has been appointed to the Martin White chair of sociology tenable at that School. The title of reader in education in the University of London has been conferred on Mr. A. C. F. Beales in respect of the post held by him in King's College.

THE bequests recently made to the University of Sheffield under the wills of the late Sir George Franklin, who died in 1916, and Miss Daisy Franklin, who died in 1948, will be used for the endowment of the full-time chair of medicine in the University, which will henceforth be known as the Sir George Franklin chair of medicine. Sir George Franklin was pro-chancellor and chairman of council of the University during 1905-16.

THE second annual meeting of Committee E-14 on Mass Spectrometry, of the American Society for Testing Materials, will be held during the week beginning May 24 at the Jung Hotel, New Orleans, Louisiana. Forty-six papers will be presented, covering isotopic abundance determinations, ionization potentials, solids analysis, high molecular-weight analysis, and new mass-spectrometer techniques and developments. During the week the election of new officers of the E-14 Committee will be made. Further details can be obtained from Mr. William Priestley, jun., Standard Oil Development Co., P.O. Box 121, Linden, New Jersey.

THE annual Cornell University summer laboratory course in techniques and applications of the electron microscope will be given during June 14-26 in the Laboratory of Electron Microscopy, Department of Engineering Physics, under the direction of Dr. Benjamin M. Siegel. The course is designed for research workers in academic institutions or industry who have recently entered the field of electron microscopy or who are now planning to undertake research problems involving applications of this instrument. Inquiries should be addressed to Dr. Siegel at the Department of Engineering Physics, Rockefeller Hall, Cornell University, Ithaca, New York.

THE Textile Institute is offering a Cotton Industry War Memorial Scholarship, of maximum value £950, for a three-year course in textile technology at an advanced level, with provision for industrial training and experience of a special character in Britain or overseas. The closing date for applications is April 30. The Institute is also offering a Peter Coats Scholarship, of maximum value £200, for one year of full-time study preparatory to taking up a course in textile technology at a university or college. The closing date for applications is May 31. Candidates for both these awards must be male British nationals less than twenty-four years of age. Application forms and further details can be obtained from the General Secretary, Textile Institute, 10 Blackfriars Street, Manchester 3.

THE second general assembly of the Italian Geophysical and Meteorological Society will be held in Genoa during April 23-25. The first two days will be devoted to the reading of twenty-three papers, and the final day will be reserved for the discussion of the Society's affairs and an excursion. Further information can be obtained from the Società Italiana di Geofisica e Meteorologia, via Balbi 5, Genova.

MEDICAL USES OF ATOMIC ENERGY*

RADIOACTIVE isotopes, which are produced by neutron irradiation in atomic piles, or extracted from the waste products of nuclear fission, or derived from the bombardment of targets in the cyclotron, are influencing many aspects of medical research and certain forms of treatment. Their peculiar merit is that, while undergoing exactly the same metabolism as ordinary matter, they can be traced through the body with great sensitivity, using suitable instruments, or, when larger amounts are employed, useful radiation effects can be caused in certain parts of the body.

The high sensitivity of detection of radioactive isotopes makes it possible to observe the dynamics of many physiological processes without disturbing the equilibria being measured. Radioactive iron, for example, is used for determining whether a particular type of anaemia is due to the failure of the iron to be absorbed from the diet, or to the iron being absorbed but not properly used in the haemoglobin and the red cells. More complex chemical compounds, or even organic structures, are 'labelled' with radioactive atoms and their metabolism studied. Thus, penicillin can be made containing a radioactive sulphur atom, or vitamin B₁₂ with radioactive cobalt, or blood cells with radioactive chromium. The problems studied with such labelled compounds include the formation of bones, abnormalities of salt excretion in adrenal diseases, the mechanism of conduction of impulses along nerves, the formation and repair of teeth, the function of the thyroid, and the metabolism in the body of steroid, peptide and carbohydrate molecules. In most of these fields the skilful use of radioactive isotopes yields information which could not otherwise have been obtained.

Measurements on patients are not limited to tests depending on the removing of body fluids; they can also be made *in situ* and are of much value to the surgeon in the operating theatre. In fractures of the head of the femur the question of whether the blood supply has or has not been abolished can be answered by injecting radiophosphorus a few hours before the operation and measuring its relative concentrations in the head and shaft of the bone. Radiophosphorus is also used during operations on brain tumours to indicate the extent of operation necessary. By intravenously injecting small amounts of radio-sodium solution and measuring the activity with counters placed on the skin, the velocity of the blood flow in the veins can be measured in conditions where thrombosis is likely to occur. The same method can be employed in measuring the speed of blood circulation around the whole body, or through the lungs alone. The dosages used in these investigations are so small that the irradiation received by the body during any of these tests is less than that received in ordinary X-ray examinations.

Turning to the use of radioactive isotopes in treatment, the aim is to deliver the maximum dose to the places to be destroyed with the minimum dose anywhere else. In one type of treatment the isotopes are applied externally or into body cavities. Thus, skin lesions are treated by applications of sheets of

plastic impregnated with radiophosphorus. Cancers involving the bladder lining can be treated with a solution of radiobromine contained in a distensible bag which can be inserted into the bladder. If a suitable colloid is introduced into a cavity in the body it will diffuse out only very slowly, if at all. The linings of the abdomen and of the chest may become involved with growth, causing distension of these cavities with fluid; the surface layers of such growth may be selectively irradiated by the introduction of a colloidal suspension of radioactive gold into the cavity.

Quite a different technique is to inject colloidal gold particles of appropriate size into the bloodstream, which will carry them until they are arrested in the fine capillaries of the lung. In this way it may be possible to treat cancers of the lung. Another possibility is to use the technique of cardiac catheterization, in which a fine tube is passed along the vein, through the heart and into an artery which feeds that part of the lung where a cancer has developed. Radioactive colloidal gold is thus located mainly in the region where the cancer is. If the particles are made small enough they will pass through all the lung capillaries and eventually be absorbed by the reticulo-endothelial cells, most of which are in the liver. This provides a method of irradiating the liver only, which may prove useful in treating certain types of leukaemia and cancer of the liver.

By making use of the chemical properties of the radioactive substances it is also possible to deposit the radioactive isotopes where required. The classic case is the treatment of toxic goitre merely by giving the patient a drink of water containing less than one ten-millionth of a gram of radioiodine. In some cases of cancer of the thyroid the secondary deposits can be induced to take up iodine in the same way as normal thyroid tissue. Hence, multiple deposits can be treated with radioactive iodine when they are too widespread for surgical removal.

Although the medical applications of radioactive isotopes are barely ten years old, they have already been developed for tests of the very highest value in research and of great convenience and some importance in routine clinical medicine. Their most important value lies in the clearer understanding that they are giving us of the body processes involved in health and disease, and in this type of investigation they are proving to have an increasing scope and power which is transforming many lines of medical investigation.

THE PARLIAMENTARY AND SCIENTIFIC COMMITTEE

THE annual report for 1953 of the Parliamentary and Scientific Committee* records a Parliamentary membership of 166 in 1952, while some thirteen further scientific and technical organizations were elected to membership during the year. Meetings of the general committee were addressed during the year by Sir Frank Engledow, on primary factors in

* Summary of a lecture by Dr. H. H. Pochin, being the fifth of the series of public lectures arranged by the Atomic Scientists' Association and the Department of Extra-Mural Studies of the University of London (see also *Nature* of February 27, p. 286; March 12, p. 477; March 27, p. 578; and April 3, p. 631).

* Parliamentary and Scientific Committee (an Unofficial Group of Members of both Houses of Parliament, and Representatives of certain Scientific and Technical Institutions). Annual Report, 1953. Pp. 28. (London: Parliamentary and Scientific Committee, 1954.)

African agriculture; by Mr. F. J. Curtis, on developing the managerial abilities of employees; by Mr. W. Allen, Mr. E. D. Hinchliffe and Mr. A. MacDonald, on economic benefits of a scientific factory design policy; by Sir Hubert Houldsworth and Dr. D. T. A. Townend, on coal production and utilization and the application of science thereto; by Sir John Hacking and Sir Harold Smith, on electricity and gas industries and the application of science thereto; and Dr. F. Roffey, Dr. R. F. Goldstein, Dr. R. Holroyd and Dr. M. A. Matthews introduced a discussion on the economic importance of the petrochemical industry. On June 16, 1953, it was agreed to set up a sub-committee to consider the whole question of higher technological education. The report includes the usual concise summary of representations made to the Lord President of the Council and of Parliamentary announcements relating to science and government during the year.

Addressing the Parliamentary and Scientific Committee at its annual luncheon on February 16, 1954, Dr. K. T. Compton, chairman of the Massachusetts Institute of Technology, said that technological education has been continually shaped to meet the needs of the country concerned. Civilian, as distinct from military, engineering schools were first developed in France and Germany about two centuries ago—in France, first as part of a national public-works programme under Louis XV, and then as part of an attempt to recover from the wreckage of the Revolution. In Germany, the impetus arose, first from the desire to recover from the economic destruction of the Napoleonic War, and secondly from her ambition to compete in industry and trade with Great Britain. The numerous polytechnic institutions and technical high schools thus established on the Continent of Europe were all State institutions, owing to university indifference or opposition. In the United States, the great impetus to engineering education came in the early 1860's; but in Great Britain the development of technical education was greatly influenced by the old guild traditions and laws governing apprenticeship, although Great Britain to-day has some of the world's best engineers.

Dr. Compton then directed attention to several trends which he thought were as significant in Great Britain as in the United States. First, the demand for engineers is increasing greatly and faster than the supply: the annual output of graduates from the United States engineering schools is less than half the forty thousand new engineers required. Secondly, the nature of the demands on engineers, and therefore the kind of education required to meet these demands, are changing: there is opportunity for at least some technological institutions to increase their emphasis on basic science and research, for a higher technological institution cannot just follow industrial trends but must anticipate and prepare for them. Moreover, to an increasing extent the most progressive technological institutions are providing education for many who are not planning to be professional scientific workers or engineers, but who see in these fields a good introduction to the cultural environment of to-day and a good medium for intellectual discipline. In this way higher technological education is helping to develop the industrial and social climate in which technological progress and productivity can thrive.

Stressing the importance of the factor of 'climate' and prestige within which the technologist works,

as well as the more obvious factor of his specialized competence, Dr. Compton expressed the opinion that the Government of Great Britain has been wise to support both the technological departments of the universities, through the University Grants Committee, and also the expansion of the Imperial College of Science and Technology, London. He thought that the diverse approach, through the universities and through higher technological institutions, has virtues in healthy competition, greater coverage, mutually supplementing programmes, and the general advantage of wider education, experiment and spreading of investment risks.

QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE

PART 4 of vol. 94 of the *Quarterly Journal of Microscopical Science*, issued in December 1953, was chosen as the "Centenary Number", and indeed it is a centenary worthy of commemoration. Actually the first number was published in October 1852, so that it has been in publication for just over 101 years. The first editors were Dr. Edwin Lankester and Mr. George Busk, who were active members of the Microscopical Society of London, and it started as a joint publication, the first part of the volume being the *Journal of Microscopical Science* and the second part the *Transactions* of the Society. The editors were solely responsible for the *Journal*. Each volume contained not only original contributions but also translations of foreign papers, long reviews, notes, correspondence and extracts from the proceedings of various societies whenever they dealt with microscopy. It was issued by a well-known publisher, Samuel Highley, who retired in 1855, and then it was taken over by J. and A. Churchill. It catered for biology, geology, histology and pathology—indeed, any branch of science and medicine that was served by microscopy. From the commencement a strong point was made of the provision of plates by the well-known lithographer Tuffin West, and they became one of its outstanding features.

The volumes of the first series, which finished with Vol. 8 in 1860, give the impression of being the work of amateurs. The term is not used in any derogatory sense but to imply persons who either did not use the microscope as an essential tool of their calling or, if they did, were interested in its application to other fields. The contributions lack a common aim; the unifying factor is the instrument used, with its ancillary techniques. With the "new series" a gradual change set in, and the memoirs became more and more by and for professional biologists, to whom the microscope was essential in their work. Vol. 3 of the new series contained a review of the Gregarinids with descriptions of three new species. It showed a comprehensive grasp of the subject and familiarity with the relevant literature in French and German and appeared when its author, E. Ray Lankester, was sixteen years old. After Vol. 8 N.S., the *Transactions of the Royal Microscopical Society* (a Royal Charter had been granted in 1866) were published independently. The following year, 1869, it was only the quarterly journal; at the same time, Mr. Busk left it and the young Oxford B.A., E. Ray Lankester, joined it as co-editor with his father. Two years later Dr. Lankester, a man of unbounded energy and

most varied interests, retired, and Dr. J. F. Payne, of St. Thomas's Hospital, joined as co-editor, thus maintaining the link with medical microscopy. With Vol. 16, 1876, E. Ray Lankester became chief editor, but had a varying panel of collaborators chosen from the leading biologists of the country. There followed a period of remarkable growth, which reached a peak in 1885, during which year 912 pp. of text and 62 plates appeared, and a second peak in 1894, with 904 pp. and 84 plates. The former was towards the end of a period when the microscope had greatly facilitated the study of the invertebrates. By this time the *Journal* was without equal in Great Britain and had achieved a world-wide reputation. Behind much of this work was the background of the ideas of evolution, and there grew up a sort of unity, lacking in the early years, in which each piece of morphology or embryology seemed to have a place.

The second peak was in part associated with the extended use of the microtome and the rise of vertebrate embryology, again with a distinctly evolutionary background, which occupied an increasing amount of space but not to the exclusion of the invertebrates, particularly Protozoa. During this expansion period the *Journal of Botany* and other specialist journals appeared, so that the "QJ." became more and more zoological. This tendency to restrict the scope of a publication seems to be inevitable; but it is to be hoped that it will not be carried to the extent that the *Quarterly Journal* becomes another of those journals not looked at save by workers in its own narrow field. E. Ray Lankester remained editor until Vol. 64, 1919, by which time he had contributed seventy-eight articles to it, a number of them becoming classics. He retired from active participation; but his name appeared as honorary editor until his death in 1929. Vol. 64 also marked fifty years of his editorship, and this was commemorated by Prof. G. O. Bourne in a long review of the outstanding memoirs that had appeared and the many distinguished names, both British and foreign, that had been associated with the *Journal*. He directed attention to one of the principal features of its outstanding success, the universality of its appeal, and that while it "had its specialities it has never been specialised". The new editor was Prof. E. S. Goodrich, a pupil of Lankester's at University College, London, whom he took with him when he went to the Linacre chair at Oxford. Goodrich's first contribution to the *Journal* was in 1893, and like his predecessor he was to prove a great editor and a great master of zoology. Three parts of Vol. 86, 1946, are taken up by a review of the work, largely by himself and his pupils, on the coelom, genital ducts and nephridia that had appeared in the fifty years since his initial contribution to the problem. He died shortly after he had corrected the proofs of this, and before it had appeared in print, and so ended a connexion of fifty-two years with the *Journal*, for the last twenty-five of which he had been editor.

With the death of Prof. Goodrich the ownership of the *Journal* changed hands, its publication was taken over by the Clarendon Press, and Dr. O. F. A. Pantin, who had joined the panel of collaborators in 1939, and Dr. John Baker became joint editors. A comparison between the earliest and the latest volumes is interesting, and shows that a number of similar problems are investigated. The techniques, of course, differ, for the plain microscope

is replaced by the electron and phase-contrast microscopes, etc., freeze drying and refined chemical (including staining) methods. It is essential to explore the possibilities and limitations of new techniques; but it seems to follow that the various contributions tend to lack the coherence so noticeable in the years before and after the turn of the century. It is interesting, too, in view of the present extensive use of photomicrographs, to find that this method of illustration was used for the first time, so far as has been traced, in one of the plates in the first volume of the *Quarterly Journal of Microscopical Science*.

The *Journal* is to be congratulated on its century and on the fact that it is "still going strong"; may it long continue to be the fertile source of inspiration that it has been in the past.

INORGANIC CHEMICAL KINETICS AND REACTIONS

A CHEMICAL SOCIETY symposium generally takes the form of a sort of scientific stock-taking at which progress and achievement in some chosen field are reported and the contemporary position impartially assessed. The symposium on "Inorganic Kinetics and Reactions", held at Burlington House, London, on February 4, was arranged by Dr. J. Chatt and Dr. L. E. Sutton rather to direct attention to a field of rapidly growing importance, and in his introductory remarks the president of the Society, Prof. C. K. Ingold, urged his many listeners to avail themselves of the opportunities open for British chemists to take their full share and—as he hoped—a leading part in its development.

The first paper, by Dr. H. M. N. H. Irving (Oxford), took the form of a general survey of problems and methods. After paying a tribute to Prof. Ingold for the great part he had played in raising our knowledge of the kinetics of organic reactions to such an advanced state, Dr. Irving suggested that the comparatively undeveloped state of inorganic kinetics is not due entirely to the general neglect—particularly in Britain—of inorganic chemistry as a whole, nor to the fact that inorganic reactions are often fast, for techniques for dealing with this problem are available. But while the organic chemist generally has a precise knowledge of the concentrations, compositions and detailed structures of the materials reacting in the systems he investigates, remarkably little is known in many cases concerning even the actual species which participate in an inorganic reaction such as that formally represented by the equation:

The extent to which a cation is hydrated in solution, the firmness with which the primary solvation sheath is attached, the extent and rate of ionization of hydrogen ions from an aquo-cation to form water-soluble basic species or polynuclear complexes, and the effects of complex formation with all anions present—these factors are seldom known with any accuracy, though they may be of essential significance in elucidating reaction mechanisms and kinetics in inorganic chemistry.

Techniques for measuring the rates of inorganic reactions are already numerous, though dynamic flow methods and calorimetric methods have not

yet been extensively employed. Bjerrum's effective device of working at very low temperatures (-75° to -100° C.) has already provided interesting results. Great impetus has recently been given to the field by the general availability of radioactive and stable isotopes and ancillary counting equipment and mass-spectrographs.

A feature common throughout inorganic kinetics is the complexity of the processes taking place. For the exchange reaction of ferrous and ferric ions the rate equation may be written:

$$R = [\text{Fe}^{\text{II}}][\text{Fe}^{\text{III}}]\{k_1 + k_2/[\text{H}^+] + k_3[\text{X}^-]\},$$

where the inverse rate-dependence on hydrogen-ion concentration shows that the (hydrated) species FeOH^{2+} is involved, while the term involving X^- ($= \text{Cl}^-, \text{NO}_3^-, \text{etc.}$) shows that ferric complexes of the type FeX^{2+} are participating. But while the kinetics can be interpreted by postulating a transition state of the type $(\text{III})\text{Fe}^{2+} \cdots \text{OH} \cdots \text{Fe}(\text{II})^{2+}$, the effective exchange of charge which appears to take place may involve (i) actual transfer of an electron from right to left, (ii) transfer of a hydroxyl group, or (iii) transfer of a proton from a water molecule attached to the ferrous ion to the hydroxyl group.

Exchange of a complex ML_n with a labelled ligand L^* may proceed either through dissociation (with or without an intermediate stage of aquation) or by an association process which involves an increase in the co-ordination number of the central atom. Examples of both types are known, and considerable progress has been made in correlating the ease of exchange with the type and strength of bonding in the complex. In organic chemistry, stereochemistry is dominated by the tetravalency of the carbon atom; but in inorganic chemistry, planar, tetrahedral and octahedral dispositions provide a variety of new problems, some of which would be dealt with in the next paper. As an illustration of the unsolved problems of inorganic mechanism, Dr. Irving concluded by quoting the reaction of $D - [\text{CoCo}_3(\text{L}, \text{pn})_2]^+$ with a 100 per cent excess of *d,l*-tartaric acid whereby the dextro-form displaces carbonate ion preferentially from the complex, thus effecting a partial resolution. Is this due to differing stabilities of the complexes containing *d*- or *l*-tartaric acid, or to different rates of reaction of the two enantiomorphs with the carbonatecobaltic ion?

Prof. O. K. Ingold (London) then spoke on the "Mechanism and Stereochemistry of Octahedral Substitution", dealing first with the kinetics of chlorine displacement from *l*-*cis*-dichlorobisethylenediaminecobalt-III by a graded series of nucleophilic reagents (X^-) such as $\text{MeO}^-, \text{N}_3^-, \text{NO}_2^-, \text{SCN}^-, \text{Br}^-, \text{Cl}^-$ and NO_3^- . Kinetics were followed by a variety of techniques such as polarimetry, spectrophotometry, titrimetry, and the use of radioactive chlorine-36. While bimolecular reactions occur with the first three reagents named, nucleophilic substitution proceeds by $\text{S}_{\text{N}}1$ mechanism with the last four. Since optical activity is completely lost, and at the same rate, in these last four cases, the following mechanism was proposed by Prof. Ingold:

The short-lived, optically inactive intermediate contains 5-covalent cobalt-III and may be formulated as a triangular bipyramid or as a square pyramid. It can take up the substituting agent at comparably rapid rates in all the distinguishable five positions in proportions which depend in detail on the groups already present, and on the nature of that entering.

Prof. Ingold pointed out that a most confusing variety of stereochemical changes among co-ordination compounds of the type CoR_4X has been reported on replacing X by Y . If these are bimolecular and proceed by edge-displacement, the type of configurational change observed depends essentially upon the atom chosen as the reference point. If this were atom 1, the edge-displacement could be described as a *cis* $\rightarrow$ *trans* change; if at 2, as *trans* $\rightarrow$ *cis*; if at 3 or 4, as either

$d \rightarrow l$, or $l \rightarrow d$. Indeed, if certain geometrical conditions are satisfied, edge-displacement can proceed without apparent geometrical isomerization or change of optical configuration. In two cases the stereo course of an $\text{S}_{\text{N}}2$ change has been studied in detail, with the following results:

	OH^-	per cent <i>cis</i>	per cent <i>trans</i>
<i>trans</i> - $[\text{CoEn}_2(\text{SCN})\text{Cl}]^+$	$\rightarrow [\text{CoEn}_2(\text{SCN})(\text{OH})]^+$	72	28
<i>trans</i> - $[\text{CoEn}_2(\text{SCN})\text{Br}]^+$	$\rightarrow [\text{CoEn}_2(\text{SCN})(\text{OH})]^+$	75	25

showing that substitution in octahedral complexes proceeds predominantly, but not exclusively, by 'edge-displacement'. This result should be contrasted with $\text{S}_{\text{N}}2$ substitution among tetrahedral carbon compounds, which leads practically exclusively to optical inversion.

The next speaker, Prof. F. S. Dainton (Leeds), prefaced his paper entitled "Physico-chemical Mechanisms Involved in Electron Transfer" by saying that he proposed to underline some of the general remarks made by Dr. Irving. Atom transfers are certainly known, such as

and electron transfers between, for example, argon and sodium vapour are well established. But while Ti^+ and Ti^{2+} , and Fe^{2+} and Fe^{3+} give couples individually reversible at a platinum electrode so that the position of ultimate equilibrium in a mixture can be calculated from the redox potentials, these give no clue to the rate of reaction.

The fundamental principles of electron transfer reactions were then discussed by Prof. Dainton along the lines suggested by Mulliken, and by Evans and his co-workers. Vinyl compounds which are polymerized by hydrogen atoms serve as detectors for hydrogen atoms produced, for example, by photochemical electron-transfer from reducing ions, though it is always necessary to take into account possible complex formation between cations present and the

aquation background. For the first-order aquation of the corresponding cobaltammine, however,

the rate was given by $k = 0.85 \times 10^{12} \exp(-26,800/RT)$. While in this case aquation and the rate of release of thiocyanate ions was found to be catalysed by thiocyanate ions, no similar rate-enhancement was observed with the chromammine. These differences could be explained by postulating the operation of an association (S_N2) mechanism for the chromium complexes, but a dissociation (S_N1) mechanism for those of cobalt. But it should not be overlooked that the rate of exchange of water is known to be increased in many cases by increase in ionic strength, so that the catalytic effect of the thiocyanate ions might well be due to their causing an increase in ionic strength rather than to the progress of a bimolecular substitution.

The lively and prolonged discussions which followed each group of papers brought valuable contributions from a very considerable number among the audience and added greatly to the success of what was obviously an exceptionally well-appreciated, stimulating, and well-timed symposium. Since the whole of these discussions is to be reported in full by the Chemical Society in a special publication of all the papers contributed to the symposium, no attempt will be made here to indicate even their scope or quality; but they certainly suggested that the hopes expressed by the president in his opening remarks would not long await realization.

H. IRVING

UGANDA PROTECTORATE FOREST DEPARTMENT

ANNUAL REPORT FOR 1952

THE annual report of the Uganda Forest Department for the year ending December 1952* makes an outstanding departure from the forestry reports of most of the British Colonies—and, it might be added, other parts of the Commonwealth—by virtue of the noteworthy position it gives to a consideration of working plans. This important branch of forestry work is dealt with under the heading of "Enumerations and Working Plans" in Chapter 3, and follows remarks on policy and legislation in Chapter 1, the form of which remains unchanged and on the lines of the official statement made by the Governor in 1948, and data on the forest estate for the year, which are contained in Chapter 2.

A working plan for a forest is not necessarily made only when an annual financial income is assured. A chancellor of the exchequer or financial minister to a Colonial Government has to provide money in his budget for non-productive objects of indirect benefit to the community. In a similar fashion, forests may have to be managed, especially protection forests, or those which secure amenities for the public but do not make a direct financial profit. As regards financially productive forests, a working plan is necessary even though the area may be run on a short rotation for the public,

often to provide the agricultural villager with fuel. Once under a working plan sanctioned by the highest Civil authority in the country, a forest is safe in perpetuity so long as the prescriptions laid down for a short period of years are strictly carried out. A perusal of the chapter in this report devoted to this branch of forestry work shows that these premises are well understood by the Government and the Chief Conservator of Forests in Uganda. Equally interesting are the remarks on the methods upon which the enumerations of the growing stock of the forests are being undertaken; for a plan cannot be drawn up until as detailed a knowledge of the contents of the forest as possible is obtained.

Five new working plans were approved during the year, and progress was made in the compilation of a number of other plans and revisions, some being in first draft during the year. One of the sanctioned plans, the Mbele Plantations for 1953-60, is for pole and fuel plantations covering a coppice rotation; another prescribes the management of six protection central forest reserves in the northern Acholi hills; a third, the West Nile Southern Escarpment hill-tracts working plan for 1952-61, prescribes the protection and maintenance of nine local forest reserves in the West Nile. The mere names and the reasons for these working plans indicate the sound lines of work which the Chief Conservator is engaged upon.

It is all the more satisfactory and of promise for the future that working plans are in force or in preparation for local forests under African management. The area of pole or fuel plantations, twelve in number, managed by African local governments amount to 7,691 acres, of which several are already under working plans. This type of work in tropical forests involves a considerable amount of research, and the staff of the Department are to be congratulated on the amount of work which has been carried out on this account. E. P. STEBBING

CARNEGIE INSTITUTION OF WASHINGTON

ANNUAL REPORT

DR. VANNEVAR BUSH'S annual report* as president of the Carnegie Institution of Washington mentions as the most interesting of the Institution's research activities in the year ending June 30, 1953, an entirely new approach at the Mount Wilson and Palomar Observatories to the problem of the general magnetic field of the sun. Observations made possible by the greatly increased power of the new Mount Wilson gratings, and new photoelectric techniques have confirmed the existence of a general magnetic field much weaker than earlier measurements suggested and limited to the neighbourhood of the poles. Preliminary values obtained with the new Hale telescope and more advanced techniques now available indicate that a drastic revision of the distance of the Andromeda nebula and other distances dependent on it will be required: the earlier values of the distances and linear dimensions of all nebulae must be approximately doubled

* Uganda. Annual Report of the Forest Department for the Year ended 31st December, 1952. Pp. II+88. (Entebbe: Government Printer, 1953.) 1.75s.

* California Institute of Technology. Annual Report 1952-1953. Comprising the Reports of the President, the Secretary, the Comptroller, and other Administrative Officers. Pp. v+142. (Pasadena, Calif.: California Institute of Technology 1953.)

and their luminosities quadrupled. During the year a new and extremely sensitive light-measuring device in the form of a photon-counter has been developed for the Hale telescope, by which light received from an object can be measured at the extreme limit that can be photographed with the 200-in. telescope.

Improved techniques have now surmounted experimental difficulties which hampered work at the Geophysical Laboratory on rock-forming minerals mixed with volatile components, and a better understanding is being obtained of the process of formation of granite, as well as new insight into the chemistry of the micas. Apparatus is now in use which can give pressures up to 200,000 lb./sq. in. at temperatures of 1,000° C. or higher, and studies with this apparatus indicate that the solubility of solid inorganic substances in compressed gases can reach unexpected magnitudes.

In the Department of Terrestrial Magnetism, by measuring the incorporation of isotopically labelled compounds in bacterial cells, flow patterns have been obtained which account for more than 80 per cent of the carbon incorporated: this is converted from glucose to the amino-acids, purines and pyrimidines eventually used in the synthesis of protein and nucleic acid molecules. Studies of the Krebs cycle show that in *Escherichia coli* growing with glucose as the sole source of carbon, the Krebs cycle acts chiefly by synthesizing aspartic and glutamic acids, and contributes little to oxidation, although in certain circumstances the flow alters to emphasize oxidation rather than synthesis.

Studies of winds in the upper atmosphere and a revised understanding of the electrical conductivity of the ionosphere now suggest that the electrical currents which produce magnetic storm effects are primarily in the atmosphere, and the wind motions causing them are initiated by radiations and possibly by particles from the sun. In the Department of Plant Biology, the biochemical group has shown that the reversible changes in the absorption spectrum of chlorophyll in certain photosynthetic bacteria are increased when oxidizing substances are added to the bacteria and decreased in the presence of substances, such as peptone, that enter into the normal metabolism of the cells. The change, by absorption of light, of protochlorophyll to the photosynthetic pigment, chlorophyll, occurs in leaves even at -77° C., although the rate of change and its extent diminish below 0° C. Studies in the Department of Genetics of reproduction in bacteriophages have partly confirmed the view that infection of the bacterium *Escherichia coli* by bacteriophage T₂ begins with the injection of pure phage nucleic acid into the cell. The findings are consistent with an intracellular population of multiplying non-infective phage and with the idea that non-infective phage particles consist of or contain nucleic acid. Presence of a mutation-inducing factor at a particular locus in a maize chromosome results in the production of a large number of mutations affecting the action of genes on either side of it.

In the Department of Embryology, a noteworthy advance has been made in a study of the action of the blood circulation, especially of the lungs of the new-born animal just before and just after the time of its birth. Further work on the physiology of uterine muscle has shown that progesterone produces its effects on muscle tissue by altering the rate of access of potassium ions to the contractile tissue.

VARIATION WITHIN INBRED STRAINS OF MICE

By DR. H. GRÜNEBERG

University College, London

THE use of inbred strains of mice and other rodents has been widely recommended for experimental purposes. The advantage of highly inbred over ordinary mice is held to be that the members of an inbred strain are genetically very similar and hence presumably more uniform both anatomically and physiologically. As a consequence, an experiment carried out with a given number of inbred animals is expected to give a result of greater precision than if the same number of ordinary mice had been used. Moreover, an experiment carried out by A would be more accurately repeatable by B if both use the same standard inbred strain of animals than if they use batches of ordinary mice.

The confidence with which inbred strains have been recommended for general experimental use rests largely on the prestige of the mathematical theory of the results of inbreeding; or, more properly, of an early phase of that theory. For example, it can be calculated what progress towards homozygosity will be made by ten or twenty generations of brother-sister mating in the absence of selection. In practice it is, however, difficult to avoid selection in favour of the more fertile heterozygotes, and it has recently been shown¹ that a comparatively moderate advantage of the heterozygotes over the homozygotes can greatly retard and indeed completely arrest the progress towards the fixation of genes by inbreeding. Recent work in *Drosophila*² has shown that the selective advantage enjoyed by many genes and gene complexes in the heterozygous, as compared with the homozygous, state is surprisingly great; no comparable data are yet available for the mouse or other mammals. Heterozygosis in an inbred strain is also replenished by mutation and hence depends on the total spontaneous mutation-rate, for which no estimates are as yet available in the case of mammals; it may be high as compared with *Drosophila*, as was found to be the case for the induced mutation-rate in a number of selected loci in the mouse³. Taken together, residual heterozygosis and heterozygosis due to mutation constitute the irreducible heterozygosis in a pure line. Its level will be reflected in the extent to which the pure line is split up into genetically different sub-lines in the course of continued inbreeding. It is the level of this irreducible heterozygosis (rather than its source) which is of primary interest for all practical purposes.

That pure lines of mice do, in fact, split up into genetically distinguishable sub-lines in the course of continued inbreeding has become obvious in recent years through the appearance of coat colour mutations, of histo-compatibility genes and, more recently, of structural differences such as the number of pre-sacral vertebrae^{4,5}. In all these cases, changes in a single feature only have been studied, and while such facts have given qualitative evidence for sub-line development, they have not been suitable for quantitative studies of that process.

Material highly suitable for the quantitative study of variation within pure lines has become available

in recent years. It has been discovered that there exists a multitude of well-defined variations in the skeleton of the mouse⁸⁻¹², most of which had previously escaped detection. More than a score of these variants have so far been studied to a greater or lesser extent, and others remain to be sorted out. These include various features of the skull and teeth, of the vertebrae (particularly in the cervical and upper thoracic region) and of the pelvis. Few, if any, of these variants are pathological. Some are confined to a single pure line; others are found in several inbred stocks though usually in different percentages; these differences between pure lines are evidence that these entities are, to some extent, under genetic control. In most cases, normals can be distinguished from abnormals without ambiguity though the degree of abnormality is often variable. While most of these variants can thus be treated as all-or-none characters, none of those so far studied is due to the segregation of a single gene; there is evidence that many of these entities have a multifactorial background^{8,9,10}; it seems that most of these characters are examples of 'quasi-continuous' variation⁸ in the sense that they are satellite characters of continuous (metrical) variations which tend to appear whenever part of the continuous distribution crosses a particular threshold; for one case (absence of third molars), this has been directly demonstrated, the continuous variable being the size of these teeth when present. As there are thus numerous characters (few of which seem to be closely correlated with each other^{8,11}) which are each under the control of many genes, the simultaneous study of all these entities within a pure line is a very sensitive tool for the discovery of genetic differentiation between sub-lines.

In Table 1 is given the percentage incidence of eleven such variants in the three pure lines *O57BL/Gr*, *OBA/Gr* and *A/Gr*. All three lines were well-established inbred strains when first imported from the United States in 1932, and brother-sister mating has continued ever since. The *O57BL* stock consists of four sub-lines which fall sharply into two groups (1 + 2 and 3 + 4, respectively); all these trace back to a pair born in 1941; from the common ancestor of all four sub-lines to the common ancestor of 1 and 2 there are about nineteen generations, and about fifteen generations to the common ancestor of 3 and 4; the main bulk of mice in 1 and 2 are four generations from their common ancestor and those in 3 and 4 are six generations. Four out of eight variants in Table 1 which occur in the *O57BL* strain show highly significant differences between groups of sub-strains (1 + 2 as compared with 3 + 4). In another two instances, one of the two groups is split up further (1 vs. 2, and 3 vs. 4), and in one instance (not given in Table 1) there is clear evidence¹¹ for a further splitting up of families within a single sub-line. Similar evidence comes from other mouse pure lines (ref. 11 and unpublished). While much more work is needed to fill in the details, it is obvious that mouse pure lines are far less homogeneous genetically than has been commonly assumed. Nor can this situation be improved by cutting down the stock periodically to the offspring of a single pair as is customary in some laboratories; while this reduces the co-existence of genetic differences in space, it increases genetic fluctuations in time.

Apart from the genetical variation due to sub-strain formation and due to sex, the skeletal variation

Table 1. PERCENTAGE INCIDENCE OF ELEVEN SKELETAL VARIANTS IN THREE INBRED STRAINS OF MICE; FOR ONE OF THEM (*O57BL*), DATA FOR TWO GROUPS OF SUB-LINES ARE GIVEN SEPARATELY (SIGNIFICANT DIFFERENCES IN ITALICS).

The percentages refer to animals except in the variants marked with asterisks, which refer to sides of animals

Variant	Ref.	<i>O57BL/Gr</i>		<i>OBA/Gr</i>	<i>A/Gr</i>
		1 + 2	3 + 4		
Interfrontal	9, 10	54.7	78.3	86.2	11.7
Parted frontals	9, 10	1	3	83	29
Pre-anheloid					
preoptic sutures*	10	25.6	43	94.5	99.5
reduced metopias					
roots*	10	1.5	0.5	72.5	22.5
Absence of 3rd molars	6, 11	0.2		17.9	3.5
Dysmorphism of O1 and O2	6, 11	43.5	51.5		
Cervical fusions	6, 11	3.7	11-63.7	0	0
Dystopia tuberc. ant. of O6	6, 8	0	0	6.4	0
Lumbo-sacral variation, ♂♂	11	21.3	5.3	?	17.3
For. acetabuli perforans*	8	0	0	64.8	0
Dysmorphism ischio-pubis, ♀♀	8, 11	25.6	85.1	0	0
		28.6			

within a pure line of mice is mainly due to intangible factors which affect individuals within a litter (or even sides of an individual) as units and which are commonly described as accidents of development; these accounted for more than 80 per cent of the total variance in three-quarters of the characters studied¹¹. The remainder of the variance is due to environmental factors which tend to affect litters as a whole, such as litter size, parity, maternal age, gestation length and, in one instance at least (size of third molars¹²), lactation. The overall picture is thus similar to that found in previous analyses of the sources of variation in the guinea pig and in the mouse.

As mentioned above, the genetic background of most of, or all, these skeletal variants is multifactorial. As such, one might expect them to be easily influenced by changes of the (pre-natal) environment. Indeed, quite a small change in the diet of the parents (from diet 86 to diet 1 of the Rowett Research Institute) had a clearly detectable influence on a metrical character in the *A/Gr* pure line, the size of the third molars¹². A drastic change of diet (from the near-optimal diet 86 to a very unbalanced regimen of oats and a little hay) massively changed the incidence of nine out of twelve variants studied in the *O57BL/Gr* pure line (Table 2¹³). The changes were by no means all in the same direction; the incidence of some variants went up, that of others went down, while a few characters did not seem to be influenced at all. A particularly interesting case is that of dysmorphism of the second thoracic vertebra in which the spinous process is split longitudinally. This variant did not occur in the controls, but was common on the oats diet; it is found rarely (about 1 per cent) in a distant branch of the same *O57BL/Gr* sub-strain and is very common, on a normal diet, in the *O57BL-b* sub-strain maintained at the Jackson Memorial Laboratory, Bar Harbor, Maine, U.S.A. Evidently, all these branches of the *O57BL* 'family' are capable of producing this variant; in some sub-strains the feature is largely above the threshold, while in others it crosses it but rarely. But even in a sub-strain in which the variant is normally completely submerged, it can be raised above the threshold by a suitable change of diet.

Table 2. PERCENTAGE INCIDENCE OF OBTUSE VARIANTS ON TWO DIFFERENT DIETS¹

Variant	Diet 86	Oats	χ^2	P
Interfrontal	36.5	57.1	8.27	0.004
Parted frontals	3.5	20.0	6.17	0.015
Squamosal-parietal fusion	15.8	1.4	8.56	0.004
Occipital-parietal fusion	7.9	4.8	0.51	0.50
Dysmorphism of C1 and C2	51.5	51.4	0.00	0.99
Dysmorphism of Th 2	0	16.4	—	0.000

Features of the skeleton are the material of the vertebrate paleontologist and, to a large extent, of the physical anthropologist. There has been some bias in ascribing skeletal differences, particularly between human groups, to heredity rather than to factors of the environment. The facts just related are a salutary reminder that even the skeleton is far from immune from environmental influences, and a skeletal difference between two populations (whether in space or in time) may well have a purely nutritional basis. Of course, it would be absurd to suggest that long-continued trends in skeletal change can be accounted for on this basis.

The total variability of a population is commonly regarded as the sum of its genetic and environmental components. On the basis of this reasoning, it has sometimes been taken for granted that the reduction of the genetic variance by inbreeding will automatically be accompanied by a corresponding reduction of the total variance. An inbred strain (apart from sub-line formation) should thus be less variable than a genetically mixed population. This expectation based on general grounds clearly requires to be confronted with reality. This may be done by comparing the variability within pure lines with that of crosses between pure lines^{1,2}. From the data so far available, it is certain that inbred mouse strains are by no means always less variable than genetically mixed populations. On the contrary, in several cases, the pure lines are far more variable than the F_1 and even the F_2 generations derived from crosses between them. This is in agreement with recent work on *Drosophila*^{11,12}, *Primula*¹³, *Lycopersicon*¹⁷ and other organisms, and evidently means that, at least for some of the multifactorial characters here considered, the homozygous state tends to be less stable developmentally than the heterozygous condition. (This incidentally means that, in biometrical genetics, it is no longer admissible to treat the total variance as if it were the sum of the environmental and the genetic variance. That treatment implies that the two components are independent of each other, whereas it now appears that the environmental may be a function of the genetic variance.) While, in some of the cases just considered, pure line animals are more variable than heterozygotes, the situation is clearly quite different, for example, in the case of antigenic characters (histo-compatibility genes, etc.) where, in tissue transplantation experiments, the reaction of pure-line animals is vastly more uniform than that of a genetically mixed batch of mice. Similarly, in cancer research, the superiority of pure-line mice has been established beyond doubt. [See also p. 686 of this issue of *Nature*.]

Summary. There is evidence that pure lines of mice are much less homogeneous genetically than is widely believed. It also appears that, in the case of some multifactorial characters at least, the homozygous state tends to be less stable developmentally than the heterozygous one. It follows that, while

pure-line mice are superior material for certain types of experimentation, they may be inferior to genetically mixed animals for other purposes. [Jan. 1.

RADIOCARBON AND SOME APPLICATIONS IN BIOCHEMISTRY

By DR. E. BRODA and DR. L. SVERAK

I. Chemisches Laboratorium und II. Physikalisches Institut, University of Vienna

FOR the biochemical investigations to be undertaken with radiocarbon in these laboratories, measuring methods of special sensitivity had to be developed. In particular, the Geiger counting of carbon dioxide gas is now carried out here as a routine method. At first, carbon dioxide at a pressure of up to 5 cm. mercury was added to the usual argon-alcohol mixture¹. Later it was found, contrary to the experience of previous authors, that Geiger counters can be operated with fillings of pure carbon dioxide². A Neher-Pickering quenching circuit is used; resolving power is small, but this does not matter as the gas-counting method is in any event used for weak samples only. The counters have a volume of about 25 c.c., and are filled to a pressure of 40 cm. mercury. The plateau is excellent (Fig. 1), and is not critically affected by water or mercury vapour. The measured activity is, of course, strictly

Fig. 1. Typical plateau of carbon dioxide-filled Geiger counter at a pressure of 80 cm. of mercury. (Enough counts were taken to exclude statistical fluctuations)

Fig. 2. Activity as a function of carbon dioxide pressure

proportional to pressure (Fig. 2). No prolonged pumping is required between the fillings, so that twenty or more samples can be measured per day. No 'memory effect' was ever observed. Numerical comparison shows that for weakly active samples of a mass of the order of a millimole, this method of measurement is probably the best⁴. In particular, it exceeds in sensitivity the determination of radio-carbon with the window counter by two orders of magnitude.

More recently, Dr. M. Reinharz, of these laboratories, has tested in Brussels, in collaboration with Dr. G. Vanderhaeghe, a photographic method for the assay of radiocarbon⁵. A solution of the active material is introduced into a glass capillary, which is embedded in an electron-sensitive nuclear emulsion by pouring the liquid emulsion over it. After a few days, the plate is developed and the beta-ray tracks are counted under the microscope. The background in this method is very low ($\sim 10^{-18}$ curie/cm. tube-length). Thus, activities can be measured smaller than those measurable with any other method by a factor of at least 10^3 . The volume of the capillary being minute ($\sim 3 \times 10^{-8}$ c.c./cm.), the method is useful mainly for very small samples. Such samples occur in the analysis of chemical fractions from small organs of animal or plant origin. The method will be suitable for measuring the activities of individual cells.

The gas Geiger counter has been used to re-determine the capture cross-section of the carbon-13 isotope for thermal neutrons⁶. It has been found that this cross-section is at least ten times smaller than was believed previously, and cannot much exceed that of carbon-12. It follows, then, that the major part of neutron capture in natural carbon is due to carbon-12, which is eighty-nine times more abundant than carbon-13.

One of our main problems in biochemistry is that of the metabolism of individual tissue cultures of animal origin. Owing to the smallness of the masses of these cultures (dry weight of the order of 0.01 mgm.), very little is known about this metabolism.

In collaboration with Dr. L. Stokinger and his group, of the Histological Institute of the University of Vienna, we have fed these minute tissue cultures radio-glucose and -fructose of exceedingly high specific activity. After the usual incubation period of two days, weighable quantities of suitable carriers, for example, fats or amino-acids, are mixed with the cultures, chemical separations are performed, the individual fractions obtained are subjected to combustion, and their activities measured. These activities indicate how much sugar the tissue had converted into the fractions. Very careful tests were carried out to exclude spurious activity due to adsorption⁷.

It has been found that individual cultures of connective tissue take up in two days around 2×10^{-6} gm. of sugar each, corresponding to about 0.2 per cent of their own weights. About one-half of the activity recovered in metabolites appears as that of the end-product of respiration, namely, carbon dioxide. The activities of the following fractions have also been measured: free amino-acids + bases, proteins (after hydrolysis), lipoids, carbonic acids⁸. These fractions are being sub-divided.

It is intended to compare by this method the metabolisms of normal and cancerous cultures of similar origin. Using for such studies tissue cultures, the metabolism of uniform ('pure') tissue and not that of an ill-defined complex mixture of different tissues (as in the case of experiments with whole animals, or even tissue slices) is observed.

The very active sugars supplied to the cultures have been prepared by photosynthesis^{9,10}. Radio-active carbon dioxide is assimilated by green leaves, and the sugars are extracted. To gain specific activity, a leaf of small mass (dry weight c. 6 mgm.) is induced to take up as much radioactive carbon dioxide as possible. No carrier is used in the extrac-

Fig. 3. Typical radiochromatogram on paper after passage of the solution through the ion exchanger (butyl alcohol-acetic acid-water)

Fig. 4. Paper radiochromatogram of the sucrose eluted from the chromatogram shown in Fig. 3

tion. Naturally, precipitation reactions are excluded, as the total yield of sugar is less than 1 mgm. The sugars remain in the liquid phase, and are separated and purified by ion exchange and paper chromatography. The purity of the sugars (Figs. 3 and 4) is very satisfactory. Specific activity, starting from carbon dioxide containing 12 per cent carbon-14 dioxide, is up to 135 $\mu\text{C./mgm.}$, corresponding to $\sim 3 \times 10^{11}$ disintegrations per gm. and per min. Using the gas counter, 3×10^{-11} gm. of this sugar, or the equivalent amount of its metabolites, can still be measured with reasonable precision.

Biosynthesis has also been used for making radioactive tobacco mosaic virus¹⁰. In the first experiments, the virus was made by exposing to radioactive carbon dioxide leaves which had been infected four months previously. Yields of virus—purified by repeated isoelectric precipitation, and tested by electrophoresis—were mostly around 0.1 per cent, referred to the weight of the fresh leaf. The specific activity of the virus was of the order of 0.1 per cent of that of the carbon dioxide used. The fact that the virus showed radioactivity indicates either that growth of the virus is still going on after this long period, or that the virus, at stationary concentration, still takes part in metabolism.

In a further set of experiments¹¹, the radioactive carbon dioxide has been offered to rapidly growing virus a few days after infection. It has been found that in a certain time interval the specific activity of the virus is independent of the 'age', that is, the time since infection, while the total activity increases with age. Both the specific activity and the total activity of 'young' virus exceed considerably that of 'old' virus in that interval.

Our colleague, Prof. O. Hromatka, has synthesized butter yellow (dimethyl amino-azobenzene) from radioaniline and inactive dimethyl aniline¹². The

material is being used by us jointly with Drs. W. Zischka and K. Karrer, of the Institute of Pathology of the University of Vienna, for determining the metabolism of this compound, which produces liver cancer in rats. After oral application of 3 mgm. in olive oil in a single dose, by probe, it is found that a fair amount of radiocarbon is absorbed by the liver, but is excreted again with surprising speed, that is, within some weeks.

O. Hromatka has also demonstrated, in a different study, that *Acetobacter* incorporates carbon from radioactive carbon dioxide during submerged vinegar fermentation. On the other hand, the acetic acid produced shows very faint radioactivity only. Possibly the active acid originates in a biochemical process different from the predominating process, that is, from the process of direct oxidation of alcohol¹³.

Finally, Dr. K. Kratal has shown in experiments on the biogenesis of lignin that growing plants (beans, spruce) incorporate radioactive coniferin. The coniferin was either implanted into the cambium or introduced through the roots. The absorption has been proved both by Geiger counting¹⁴ and by radioautography. The coniferin has been made^{15,16} either from radioactive carbon dioxide by a Grignard type process or from active malonic ester, and is labelled in the 3- or 2-position, respectively. The findings lend support to the idea, put forward a long time ago, that coniferin is one of the main structural units of lignin.

Similar experiments are in progress with radioactive syringin and the glucoside of radioactive *p*-oxy-coumaric alcohol¹⁶. Along with coniferin, these glucosides are believed to be precursors of the lignins of angiosperm and especially of monocotyledonous plants.

Our work has been generously supported by the Österreichische Akademie der Wissenschaften, the Österreichische Krebsgesellschaft (Sonnleithner-Stiftung), the Österreichische Stickstoffwerke, Linz; the Österreichische Tabak-Regie, and by the Van t'Hoff Fund, Amsterdam. We also wish to thank Prof. E. Schmid, and especially Prof. L. Ebert, without whose constant active interest and help little of the work could have been done.

Effect of Molecular Weight on the Cross-linking of Siloxanes by High-energy Radiation

RECENT work has shown that many long-chain polymers^{1,2} can be cross-linked by high-energy radiation; although polymers containing only carbon atoms in the main chain have been studied in great detail, the same effect has been observed in polymers in which the main chain comprises alternating carbon and oxygen atoms ('Carbowax') or silicon and oxygen (silicones). There is a considerable amount of evidence to show that for a given polymer the density of cross-linking (that is, the proportion of monomer units which are linked) is directly proportional to the radiation dose over a wide range. This renders it possible to prepare a series of samples of known (relative) densities of cross-linking. Absolute values of the density of cross-linking may be evaluated in a number of ways, including swelling measurements and determination of the minimum radiation needed to form an insoluble network or gel in a polymer of known average molecular weight.

Conversely, measurements on irradiated polymers may be used to study their average molecular weight and weight distribution. It may be shown theoretically that gel formation first occurs when there is present on the average one cross-link per 'weight average' molecule, while the subsequent shape of the gel fraction/cross-linking density curve is directly related to the molecular-weight distribution in the original polymer. If the cross-linking density is proportional to radiation dose but is independent of molecular weight (apart from very small end-effects) the radiation dose, R , needed to promote incipient gel formation in a number of polymers of similar structure should be inversely proportional to their weight average molecular weight, M .

Lawton, Bueche and Balwit³ have found that in a number of polyethylene samples of varying molecular weights the radiation dose required for gel formation varies inversely as the 1.26 power of molecular weight, as against the value of 1 required by the above considerations. This would indicate that the density of cross-linking depends on molecular weight, even for long polymers. From the published data it is not clear that the molecular weights referred to are indeed the weight averages, and the results might be taken to show that the molecular weight distribution is different in the various polyethylenes studied. There is, indeed, some evidence that this is the case⁴.

A much wider range of molecular weights can be studied in polysiloxanes, which are available as

fluids of varying viscosities. The relation between viscosity and molecular weight has been studied by Barry⁴. It is therefore possible to study quantitatively the cross-linking efficiency (that is, the percentage of monomers cross-linked per unit radiation) as a function of molecular weight of these polymers.

Samples of polydimethylsiloxanes of various viscosities were irradiated in evacuated silica phials or in small aluminium cans, in similar positions in the B.E.P.O. atomic pile at Harwell, or in test-tubes at fixed distances from a radioactive cobalt-60 source of pure gamma-radiation, the radiation dose being proportional to exposure time. The minimum radiation dose needed to prevent melting at temperatures of up to about 200° C. was recorded; the transition from a fluid at 20° C. to one which is infusible even at these much higher temperatures is usually very sharp. Solubility measurements confirm that this change corresponds to the incipient formation of a gel structure.

The accompanying table summarizes the results obtained on a range of polydimethylsiloxane fluids. The viscosity η is given in centistokes at 25° C., and the corresponding average molecular weights M are obtained from smoothed curves of data given by Barry⁴, while M' are average molecular weights calculated from a formula of Barry: $\log \eta = 1 + 0.0123 M'^{1/2}$. Two values of R are given for each fluid; the lower value corresponds to a dose when the irradiated sample is still fluid, and the latter when gel formation has proceeded to a sufficient extent for an infusible material to result. The radiation dose for incipient gel formation lies between these values.

It is seen that over the range of molecular weights 2,000 to 115×10^3 , the product RM is constant to within experimental error, indicating that the radiation dose needed to produce an average of one cross-link per weight average molecule is inversely proportional to the number of units in the molecule. Hence the radiation required to cross-link a given proportion of the monomer units is independent of molecular length. Only for very short molecules, comprising but a few monomer units ($M < 0.12 \times 10^4$), does RM increase. This increase is not ascribed to end-effects, since it is not progressive; it probably arises from different production methods resulting in the presence of cyclic structures and a different molecular weight distribution. The published data show that for the higher polymers there is no great difference between number and weight-average molecular weight. For these polymers, unit pile radiation results in 2.3 cross-links per hundred monomer units, independent of the molecular weight. When account is taken of the relative weights per monomer (which determine in part the energy absorbed in the pile), this value is not very different from that deduced for polyethylene and similar saturated hydrocarbons cross-linked by pile radiation.

Table 1. MINIMUM RADIATION DOSE (PILE RADIATION)* FOR GEL FORMATION

Viscosity at 25° C. (η)	2×10^3	10^4	12.5×10^4	10^5	500	200	100	50	20	10	5	3

Some Effects of Irradiation on Nylon and Polyethylene Terephthalate

In a detailed paper by Charlesby¹ on the effects of irradiation on polyethylene, he suggested that the main effect was 'cross-linking', that is, the formation of covalent bridges between neighbouring molecular chains, with the consequent loss of hydrogen. Since then, there has been a tendency to refer to the effect on any polymer as 'cross-linking' when low irradiation doses show changed solubilities in normal solvents, increased melting points, and no gross chemical breakdown², although other possible causes for these changes have been suggested³. It seems appropriate, therefore, to describe experiments on two of the polymers which have been specifically mentioned by Charlesby and Lawton, 66 nylon and 'Terylene'.

66 Nylon. Specimens of oriented 66 nylon were irradiated in B.E.P.O. with a dose of approximately 5×10^{18} n./cm.², together with the associated γ -radiation. This was fifty times the dose which first affected its solubility. Observations were that hydrogen was evolved as a gas at a rate which decreased as the dose increased. Groups of atoms were broken off and formed low-molecular weight compounds which could be extracted. On X-ray diffraction photographs of an oriented specimen, the crystallites (possibly 50 per cent of the whole) appeared to be unaffected. The strength of the irradiated material was lower than the original; but subsequent experiments have shown that complete loss of strength did not occur until after an irradiation dose sufficiently high to disrupt the crystallites.

On swelling in formic acid, diffraction photographs of the highly swollen nylon showed that the crystallites had entirely disappeared, so that the nylon together with formic acid could either have been a two-phase system, or else the nylon molecules were held together with a few loose covalent bridges. On washing with water and drying, new unoriented crystallites were formed. The degree of crystallinity was less (about 30 per cent possibly), while the intensities and spacings of the diffraction rings were consistent with the new crystallites being methyl-substituted nylon. This unoriented nylon could be oriented by stretching the specimen by an amount similar to that required to draw normal unoriented nylon. On putting the irradiated nylon, which was already highly swollen in formic acid, in a mixture of formic acid with a few per cent of hydrochloric acid, immediate solution took place (under these conditions neither peptide bonds nor $-\text{CH}_2-\text{CH}_2-$ bonds would be broken). After reprecipitation in water, the polymer had the same properties, and on casting a film rather less than 200 Å. in thickness for examination in the electron microscope, it was found

that the densities of the crystalline and non-crystalline regions were practically the same—as would be expected for an alkyl-substituted polyamide.

On irradiation of 66 nylon in the presence of air, there was a rapid loss of strength, and an analysis by British Nylon Spinners, Ltd., showed a very considerable increase in $-\text{COOH}$ end-groups (private communication).

Polyethylene terephthalate. The behaviour of polyethylene terephthalate (or 'Terylene') is completely different. To begin with, hydrogen and other gases are not evolved in appreciable quantities. Specimens of polymer chips and fibre were irradiated with approximately 1.5×10^{18} n./cm.². After this dose the fibres had completely lost their strength and begun to powder, while the chips were brittle. In specimens which were originally well crystalline the diffraction patterns looked much the same. This may be contrasted with the behaviour of 66 nylon. One polymer specimen was irradiated which had been prepared in an almost completely non-crystalline condition, and after irradiation the chips were still non-crystalline. They were then annealed at 140° C. for 1 hr., after which X-ray diffraction showed the pattern of normal well-ordered polyethylene terephthalate. This suggests (a) that extensive bridge formation could not have occurred, since any such tight linkage would inhibit the movement of molecules relative to one another, and (b) that a large number of side-groupings did not occur, since they would have shown in the diffraction pattern. The results are consistent with a straightforward breakdown of the polyethylene terephthalate chains, the breakdown products having sufficient rigidity to maintain their original positions to a fairly large extent.

End-group analyses by Imperial Chemical Industries, Ltd. (private communication), have shown an interesting difference, according to whether irradiation breakdown took place in the presence or absence of air. In the absence of air, there is a large increase in the number of $-\text{COOH}$ end-groups, whereas in the presence of a plentiful supply of air the extra end-groups were found to be $-\text{OH}$ and $\text{C}=\text{O}$, as in an aromatic aldehyde or ketone. This suggests that the molecular chains break in different places in the two cases.

I wish to thank British Nylon Spinners, Ltd., and Imperial Chemical Industries, Ltd., for providing samples of polymers.

High-energy Microturbulence in the Solar Photosphere

THE Balmer, Paschen and Brackett lines of hydrogen in the solar spectrum are much wider than they should be according to computations based on the classical widening mechanism of the hydrogen lines¹—the statistical Stark effect of the ions surrounding the emitting atoms. The amount of widening is

greater for the Paschen than for the Balmer lines; it is greatest for the Brackett lines. It seems impossible to ascribe this widening to atomic processes, since Jürgens¹ has shown in elegant laboratory experiments that the profile of $H\beta$ is explained by the statistical Stark effect of the ions. Hence, the abnormal widening of the hydrogen lines must be explained by a mechanism which is active in the solar photosphere but not in laboratory experiments. It is difficult to ascribe it to super-excitation since the wings of the hydrogen lines are formed in rather deep parts of the solar photosphere, where deviations from thermodynamical equilibrium are not very likely to occur. It can be shown that the widening is probably explained by the microturbulence of the solar photosphere, a mechanism suggested to me by Prof. A. Unsöld, of Kiel.

Computations of the profiles of the hydrogen lines have been made for two turbulent models of the photosphere. In the first, the solar photosphere is supposed to be composed of many thin vertical columns, all with the same base areas. They are evenly distributed over the solar surface, and half of them have high temperatures, the others have low temperatures. One ray of light passes through only one column, although the spectrum is made up from the composite effect of all these columns. At an optical depth τ the temperatures in these columns are given by

$$\begin{aligned}\theta_1(\tau) &= \theta_s(\tau) + \Delta\theta \\ \theta_2(\tau) &= \theta_s(\tau) - \Delta\theta \quad (0 = 5,040/T (^{\circ}\text{K})).\end{aligned}$$

The function $\theta_s(\tau)$ is for a non-turbulent model—my model VII (*l.c.*, ref. 1). We have adopted the same relation between τ , P_s and P_e as in model VII. It is provisionally assumed that $\Delta\theta$ does not vary with depth.

The profiles of the wings of four Balmer lines, seven Paschen lines, and six Brackett lines have been computed for the centre of the solar disk for this turbulent model, and for four values of $\Delta\theta$; after that a comparison of the computed profiles with the observed ones gives by interpolation an empirical determination of $\Delta\theta$. We obtain $\Delta\theta$ values ranging between about 0.05 and 0.15, but the values seem to depend slightly on the depth of formation in the solar atmosphere. Since for each point on a line profile a 'mean optical depth of formation' can be computed, we may plot the empirical $\Delta\theta$ values against the

Fig. 1

Fig. 2

corresponding mean τ -values (τ_m) in order to check whether $\Delta\theta$ varies with depth. The results are shown in Fig. 1, where τ is the monochromatic optical depth for 5000 Å. It seems that $\Delta\theta$ decreases slightly with increasing τ_m .

In the second turbulent model, it is assumed that the solar photosphere consists of many small volume elements, half of them with $\theta_1(\tau)$, the others with $\theta_2(\tau)$, distributed at random. One ray of light passes through many elements of both kinds. Here again we have adopted the same relation between τ , P_s and P_e as in model VII. The computations proceeded in an analogous way as for the first model, and the resulting $\Delta\theta$ values, plotted against τ_m , are given in Fig. 2. Here also it seems that $\Delta\theta$ depends on τ_m , but the dependence is less clear than in Fig. 1.

Both graphs show the same general aspect. It is gratifying to notice that there are no systematic differences between the points which result from the three hydrogen series. The scatter of the points is of the order of ± 0.015 in $\Delta\theta$. This corresponds with errors in the computed line profiles of ± 2 per cent (expressed in the intensity of the continuous spectrum). Since this latter value is about equal to the photometric errors in the observed line profiles, it is concluded that microturbulence is probably responsible for the additional widening of the solar hydrogen lines.

The main result of this investigation is that the temperature fluctuations in the solar photosphere are of the order of $\Delta\theta = \pm 0.1$ between $\tau = 1$ and 2.5. At $\tau = 1$, $T = 6,500^{\circ}$, giving $\Delta T = \pm 850^{\circ}$; and at $\tau = 2.5$, $T = 7,200^{\circ}$ and $\Delta T = \pm 1,000^{\circ}$. It has already been suggested by me² that the difficulties in establishing a model of the chromosphere could be solved by a 'two-temperature model'. We now find that this is probably also the case for the photosphere.

If the very great temperature fluctuations found here are confirmed by computations based on other Fraunhofer lines and on the continuous spectrum, it will be necessary to modify greatly present views on the structure of the solar photosphere.

Magneto-Resistance of Copper to 150,000 Oersted at 4.2° K.

SOME aspects of the theory of magneto-resistance in metals can best be tested in very high magnetic fields at low temperatures¹. We are therefore extending magneto-resistance measurements at helium temperatures to field-strengths of approximately 150,000 oersted. Such fields can only be produced at reasonable cost by employing Kapitza's technique² of short field pulses. De Haas and Westerdijk³ have shown that much improved efficiency results from cooling the magnet coil in liquid helium or hydrogen, and this has been discussed in detail by one of us⁴.

In our experiments the specimen was mounted inside a small solenoid immersed in liquid helium. The discharge of a bank of condensers through the solenoid produced magnetic fields up to 160,000 oersted for about one millisecond. The current in the solenoid, and the voltage generated across the specimen by an alternating measuring current of frequency about 10 kc./s., were presented on the screen of a double-beam oscillograph.

Fig. 1 shows the resistance change $\Delta R/R$ for commercial copper wire of diameter 0.1 mm.; residual resistance $R_{20}/R_{100} = 0.89$ per cent. One specimen was wound helically to be exposed to a transverse field. The other was placed mainly parallel to the field with approximately 15 per cent of its length at right angles to it. The error due to skin effect is less than a half per cent.

Grüneisen and Adenstedt⁵ have made measurements on a single-crystal specimen of copper of approximately ten times lower residual resistance in fields up to 12,000 oersted. Our transverse results are consistent within about 30 per cent with their measurements in the direction of greatest change of resistance if Kohler's rule that $\Delta R/R$ is a function of (H/R) is correct. No comparable data are available for the longitudinal case. Our results thus provide a

Fig. 1. Variation of electrical resistance with magnetic field in copper at 4.2° K. O — O, longitudinal field; ● — ●, transverse field

test of Kohler's rule in a region of magnetic field where there have hitherto been no measurements.

We are grateful to Prof. P. Grassmann for his encouragement and interest.

Anomalous Temperature Coefficient of Permittivity in Barium Titanate

WHILE engaged in tests on the 'ageing' of the permittivity of a sample of ceramic barium titanate, an observation was made which may be of interest in connexion with the theory of this substance. The sample was held at a temperature of 125° C., about 1° below the Curie point through which the sample had just been cooled. It was found that the temperature cycling due to the operation of the thermostat caused the capacitance of the sample to cycle in the opposite sense, that is, a negative temperature coefficient was observed, whereas the normal permittivity curve has, of course, a high positive slope just below the Curie point. A phase lag between the switching of the thermostat and the sample temperature was at first suspected; but a test made with a thermocouple clamped to the specimen and the on-off cycle very much slowed down gave the same result.

It is well known from X-ray diffraction work^{1,2} that for a few degrees near the Curie temperature the cubic and tetragonal phases of barium titanate can co-exist in the same crystal. It now appears that a quite finite increment in temperature is needed to change the proportions of cubic and tetragonal material, for the effect described is easily explained by postulating that this ratio remains constant during the small temperature fluctuations (0.1° C.) due to the thermostat. The relatively high negative temperature coefficient of the cubic phase swamps the positive temperature coefficient of the tetragonal phase, so that a negative coefficient of capacitance is observed. An order-of-magnitude calculation shows the plausibility of this explanation. The measured permittivity of the sample at 125° C. was 4,100, while the permittivity of the cubic phase at this temperature and its temperature coefficient would be 6,600 and - 5 per cent per deg. C., as obtained by extrapolation of the Curie-Weiss law which holds above the Curie point. Values for the tetragonal phase are more difficult to extrapolate since no empirical law has been found for the part of the curve just below the Curie point. By continuing the slight upward curvature found between 105° and 118°, a permittivity of 2,200 and a temperature coefficient of + 8.5 per cent per deg. C. has been estimated for 125° C. Using the logarithmic mixture law, it is found that 55 per cent cubic phase and 45 per cent tetragonal phase will give the correct resultant permittivity of 4,100. The resultant temperature coefficient calculated with these proportions

is then - 1 per cent per deg. C. The value found experimentally was about - 1.4 per cent per deg. C.

The question of whether the transition at around 120° C. is of the first or second order was still open recently³, although several papers have now appeared reporting in favour of a first-order transition^{4,5}. The finite temperature change (of very roughly 0.3 deg. C.) which we found necessary to cause the transition to occur may be interpreted as a further argument in favour of a first-order transition; for temperature hysteresis due to the need to activate the system over a free energy barrier is a well-known feature of first-order transitions.

It may be argued that internal strains of the ceramic are causing the observed effect, which may be likened to a mechanical yield-point phenomenon. Nevertheless, any explanation based on a second-order transition would be difficult, since the structure would be changing continuously and so the permittivity should also change continuously.

It should be mentioned that the barium titanate used was particularly pure⁶. The sample had been fired in a uniform temperature enclosure and cooled slowly from the firing temperature to minimize internal strains.

Pore-Size Distribution of Porous Iron

Ritter and Drake¹ have proved the usefulness of measuring the penetration of mercury under pressure, in order to elucidate the pore-size distribution of various substances. From elementary theory, it follows that for the radius r_p of pores filled at a pressure p :

$$r_p = \frac{-2\sigma \cos \theta}{p}, \quad (1)$$

where σ is surface tension and θ is contact angle. Substitution of $\sigma = 480$ dyne/cm. and $\theta = 140^\circ$ gives:

$$r_p = \frac{75,000}{p} \text{ A. (p in atm.)}$$

Thus, measuring up to pressures of about 1,000 atm., the method is especially suited for the determination of the distribution of pore sizes greater than 100 A. In this range other methods, based on the application of the Kelvin equation to gas adsorption and desorption data, present many difficulties².

Two different samples of porous iron were used in the present study. The first consisted of tablets (diameter, 5 mm.; height, 4 mm.), pressed from carbonyl-iron powder; the particle-size distribution of the powder, determined microscopically, is given in Table 1.

Table 1

Range (μ)	Per cent (by weight)
0-1	2
1-2	4
2-3	7
3-4	9
4-5	14
5-6	19
6-7	26
7-8	16
8-9	5
9-10	3
>10	1

The second sample was obtained by reduction of a doubly promoted iron catalyst for ammonia synthesis. The catalyst contained 3 per cent of aluminium oxide and 1 per cent of potassium oxide before the reduction. The reduction was performed in a stream of pure hydrogen for 70 hr. at 450° C. As mercury shows a tendency to wet the surface of a freshly reduced iron catalyst, the sample was made passive in a stream of hydrogen containing about 0.1 per cent oxygen³ for 48 hr. at room temperature.

The total pore-volume of both samples was calculated from the difference of specific volumes in helium and mercury. The surface areas were determined from the adsorption isotherm of nitrogen at - 196° C., following the Brunauer-Emmett-Teller method for the evaluation of the monolayer capacity (for the molecular area of nitrogen 16.2 A.² was used). The results are given in Table 2 (cols. 1 and 2).

Table 2

	1	Surface area (m. ² /gm.)		5	6	
	Pore volume cm. ³ /gm.	2	3	$\bar{r}_p = \frac{2V}{F}$	r_{max}	
		B.-E.-T.		A.	A	
			Calculated from pore-size distribution	Calculated from particle-size distribution		
Carbonyl iron	0.061	0.21	0.15	0.18	5000	8000
Iron catalyst	0.116	13.1	15.1	—	177	120

The mercury penetration was measured in an apparatus as described by Ritter and Drake¹. The maximum pressure obtainable was 1,100 atm. From a plot of the mercury-filled volume versus pore-radius, it appeared that the total pore volume of the carbonyl-iron tablets was completely filled at a pressure corresponding to a pore-radius of about 1000 A. In the case of the iron catalyst, however, about 10 per cent of the pore volume remains empty at the highest pressure obtainable. The distribution

curves, $\frac{dV}{dr}(r)$, given in the accompanying figure, were calculated by graphical differentiation of the experimental curves.

To check the results, the surface area (F) was calculated from the distribution curves with the help of the formula:

$$F = \int_0^{\infty} \left(\frac{dF}{dr} \right) dr = \int_0^{\infty} \frac{2}{r} \left(\frac{dV}{dr} \right) dr.$$

The values found are given in Table 2, col. 3, and compare well with the Brunauer-Emmett-Teller values calculated from gas adsorption data and, for the carbonyl-iron, also with the value calculated

Pore-size distribution of an iron catalyst; inset: pore-size distribution of carbonyl-iron tablets

from the particle-size distribution (from microscopic inspection the particles appeared to be spherical).

Col. 5 of Table 2 gives the values of the mean pore-radii calculated in the usual manner by dividing twice the pore volume by the Brunauer-Emmett-Teller surface area ($\bar{r}_p = 2V/F$). These values deviate from the pore radius at the maxima of the distribution curves (col. 6), which is due to the non-symmetrical form of the distribution curves.

Influence of Electronic Impact on the Rate of Sorption of Gases on to Getter Materials

THE observations by Reimann¹ and Lukirski and Ptitsyn² showed that the low rates at which some gases (carbon monoxide, nitrogen and hydrogen) are sorbed by magnesium getters can be increased considerably if the gas molecules are converted into other particles (for example, atoms or ions) by the impact of electrons. The view that this phenomenon is a general one, also existing with other getter and gas combinations, has been supported by some experimental evidence. Haase³, for example, who was the first to use a Knudsen gauge for investigation of getters, observed that barium getters only sorbed gas at pressures between 10^{-3} and 10^{-4} mm. mercury if the getter deposit was prepared with extreme care from barium distilled *in vacuo* three times and afterwards evaporated at the very low pressure of 10^{-6} mm. Even under these stringent conditions, the gettering-rates obtained were of the order of only 10 cm.³/sec. for a getter area of 120 cm.². This result appeared to show that gettering-rates of the order of 1,000 cm.³/sec., as observed when measuring with ionization gauges at such low pressures⁴, are mainly due to the electron impact occurring in those gauges.

Recently I have had an opportunity of using a Knudsen gauge (for the loan of which I am indebted to Messrs. W. Edwards, Crawley, Sussex) in combination with my flow method by which gettering-rates can be measured directly⁴ instead of deriving

them from pressure-time curves. The results obtained have shown that, contrary to expectations, electron impact has little influence on the properties of barium getters.

The experimental arrangement used for these measurements was similar to that described earlier⁴, the only difference being that the ionization gauge on the far side of the capillary (right-hand side of Fig. 1, ref. 4) was replaced by the Knudsen gauge, which had a sensitivity of 3×10^{-8} mm. mercury/mm. scale. To this gauge a side tube of 30 mm. diameter was connected in which the getter and the diode used for producing the electron impact were located. The total volume on the far side of the capillary was about 1 litre.

For pumping, a single-stage and a two-stage diffusion pump in series were used. These were operated with silicone oil, omitting any liquid-air traps. After the glass equipment had been baked for between one and three hours, a pressure of about 1×10^{-7} mm. was measured in the Knudsen gauge. Immediately after the bake, gas adsorption on the glass surfaces (total area about 1,000 cm.²) was tested. Using a pressure of 5×10^{-8} mm. on the pump side of the capillary, this adsorption came to an end after 30 sec., while sorption obtained under the same conditions by a barium getter (area 8 cm.²) was detectable for about an hour.

The barium getters were deposited from KIC-getter wires at pressures between 10^{-3} and 10^{-4} mm. During measurement of gettering-rates, the pressure above the getter was between 10^{-7} and 10^{-8} mm. The electron impact was generated in a diode consisting of either a tungsten or tantalum cathode and an anode made from either nickel or tantalum sheet, located at a distance from the cathode varying between 5 and 35 mm. The anode voltage was 100 V., and the electron current about 10 mamp. The influence of the hot cathode alone on the value measured for the rate of sorption was negligible with carbon monoxide and oxygen, but of considerable magnitude with hydrogen (≈ 500 cm.³/sec.).

As shown in the accompanying table, high gettering-rates were obtained in the systems barium-oxygen and barium-carbon monoxide without any electron impact. It was carefully checked that these high rates were neither due to, nor influenced by, the electrons passing in the ionization gauge in the manifold (left-hand side of Fig. 1, ref. 4) or by the potential across the heater of the Knudsen gauge (10 V.).

During the experiments, the getters were kept at different temperatures in the range 50°–220° C. Within the accuracy of the measurements a temperature dependence of the gettering-rate could not be detected, which means that this dependence was equal to or less than 10 per cent for barium-carbon monoxide and equal to or less than 2 per cent for barium-oxygen. From the latter value it can be

INFLUENCE OF ELECTRON IMPACT ON GETTERING-RATES (in cm.³/sec.)

Getter	Gas	Getter area (cm. ²)	Number of measurements	Average value of gettering-rate without impact	Average value of gettering-rate with impact
Barium	Oxygen	6	7	1,300	1,250
"	Carbon monoxide	6	5	1,900	1,900
"	Hydrogen	6	3	50	not measured
Magnesium	Carbon monoxide	30	2	7	12

concluded that the appropriate activation energy is smaller than 0.05 k.cal./mole. These activation energies are much smaller than those measured by Arizumi and Kotani⁶ and Kobayashi and Furaya⁷ at higher pressures (5-8 k.cal./mole).

Preparation of Dephosphorized Casein by an Enzymic Method

Plimmer and Bayliss¹ showed as early as in 1906 that the phosphorus of casein could be completely removed as inorganic phosphate by the action of 1 per cent sodium hydroxide at 37° C. in 24 hr. Acidification of the digest after the completion of dephosphorylation precipitated a substance resembling casein. Rimington² analysed the dephosphorized casein for its nitrogen distribution and noticed little difference in composition from that of casein except in amide and arginine nitrogen. The low values obtained in these two cases were evidently due to the hydrolytic action of alkali on these compounds with the production of ammonia. Plimmer and Lawton³ found besides that by the action of $N/4$ alkali on casein there was formed in addition to casein a substance or mixture of substances resembling a primary protease. The use of alkali as a dephosphorylating agent was considered to be undesirable for these reasons.

Enzymic methods have come into vogue recently in studies of this type. The preparation of dephosphorized phosphovitin by Mechem and Oloott⁴ and of phosphorus-free ovalbumin by Perlmann⁵ deserves special mention in this connexion. In the present investigation a purified preparation of phosphoprotein phosphatase obtained by us from ox spleen⁶ has been used for the preparation of dephosphorized casein. For the preparation of the protein the following method has been adopted.

1 litre of the digest containing 25 gm. of casein, 25 ml. of the pure enzyme preparation (283.5 phosphatase units per mgm. of protein nitrogen) and thioglycolic acid (activator) to a final concentration of 0.001 *M* was adjusted to a pH of 6.0 by veronal-acetate buffer. At the end of 24 hr. incubation at 37° C., a further quantity of enzyme preparation (10 ml.) was added to the digest. A precipitate had begun to separate by this time. When there was no more increase in the liberation of inorganic phosphorus (96 hr.) the precipitated protein was separated on the centrifuge, washed repeatedly with water and finally with acetone. The air-dry product weighed 16.5 gm.

The protein is a white amorphous powder lighter than casein. It is relatively insoluble in water. It is, however, soluble in dilute alkali and its solubility in

dilute acids is greater than that of casein. It can be precipitated from its alkali solution by acidifying to pH 6.0. There seems to be thus a shift in the isoelectric point of casein to the alkaline side during its dephosphorylation, presumably due to the removal of the phosphoric acid groups.

The protein has a nitrogen content of 15.7 per cent and contains about 0.03 per cent of phosphorus. Its content of arginine, histidine, cystine and tryptophan as determined by standard chemical methods resembles closely that of casein. No drastic changes appear to take place during enzymic dephosphorylation. The protein has also been found to be readily attacked by proteolytic enzymes. Alkali-dephosphorylated casein is attacked by these enzymes with difficulty⁷, possibly due to some racemization having taken place during alkali treatment. The lowering in nitrogen content brought about by alkali is another serious defect in the use of this reagent as a dephosphorylating agent. Since these drawbacks are eliminated by enzymic dephosphorylation, phosphoprotein phosphatase should prove to be a useful tool in studies on dephosphorylated proteins.

The complete amino-acid make-up of the protein is under investigation, and details of this work will be published elsewhere.

"Role of Plasmagenes"

IN Prof. C. H. Waddington's review of the book by Boris Ephrussi, "Nucleo-cytoplasmic Relations in Micro-organisms"¹, the major adverse criticisms do not, in my opinion, stand up to close examination.

First is the imputation that Ephrussi does not understand, or at least recognize, that "A property of genetic continuity is attributed to both nuclear genes and plasmagenes, but the evidence for it is of quite different, in fact almost opposite, nature in the two cases. Nuclear genes are considered to exhibit genetic continuity because they continue in existence throughout lengthy series of crosses, etc., whereas the evidence for the continuity of plasmagenes is the fact that if they are got rid of they cannot be regenerated". Now the fact is that, whereas nuclear genes and plasmagenes have been detected on the basis of somewhat different criteria, their common attribute of genetic continuity is based on essentially the same properties and observations. In so far as present knowledge permits the definition of plasmagenes and nuclear genes, Waddington might have more soundly compared them along the following lines, which would have led to a quite different approach to the point at issue.

(1) Neither a nuclear gene nor a plasmagene is recognizable unless found in differential states of activity and inactivity, or presence and absence.

(2) Both are considered to exhibit genetic continuity because they continue in a lengthy series of cell generations over which some characteristic referring back to the 'gene' is faithfully recurrent.

(3) So far as one really knows, neither can be regenerated.

(4) The two types of genes are distinguishable because in sexual reproduction nuclear genes follow precise segregational patterns based on chromosomal mechanics while cytoplasmic genes do not.

(5) The criteria and the experimental means for the detection of plasmagenes require much more careful consideration than has usually been given them in the past. (This point has often been ignored by geneticists but is critically treated by Ephrussi on pp. 116-118 of his book.)

Second is Waddington's objection that bringing plasmagenes into play to explain differentiation leads to confusion. His argument is that 'Either the plasmagenes arise *de novo* during development, in which case they are doing exactly that thing the impossibility of which is used as a means of detecting them; or they are all present, possibly in an inactive form, in the unfertilized egg, in which case they are nothing but our old and discredited friends the 'organ-forming substances' appearing under a new name and with their hair curled in the latest fashion'. In all fairness, it should have been pointed out that any difficulties in the interpretation of differentiation that arise out of the second alternative apply to nuclear genes as well as plasmagenes.

Third, in the final paragraph of the review, Waddington states: "True, he [Ephrussi] starts off on the wrong foot, arguing rightly enough (on p. 4) that development involves a 'differential [which] must have its seat in the cytoplasm', but drawing the complete *non sequitur* that 'if the cytoplasm causes differentiation it must be endowed with the power of perpetuation of cell-type'". This statement of *non sequitur* is based on the quotation of two isolated fragments taken out of context, and appears to me to be a serious misrepresentation of Ephrussi's position. Actually, in the text, both before and between the two fragments quoted in the review, there is important material that establishes the general line of argument. Essentially this material is in reference to highly significant experiments in tissue culture, which show that differentiated cell types may breed true indefinitely. *Non sequitur* implies that a conclusion has been drawn fallaciously from irrelevant premises. Reference to the text clearly shows that Ephrussi has not been guilty of such an error, since his statement in question is not derived from the purported premise but is reasonable interpretation of a set of investigational observations that are under discussion.

ADRIAN SRB

Department of Plant Breeding,
Cornell University,
Ithaca, New York.

¹ *Nature*, 172, 784 (1953).

I WELCOME the opportunity to try to clarify a little further the difference of opinion between Prof. Srb and myself, which concerns rather the question of how the 'plasmagene' theory should be incorporated into general biological thought than the particular instance of Ephrussi's book, as to the high value of which we both agree, though it seems from different points of view.

The point I wished to make in my review was that many approaches to the 'plasmagene problem' seem

to me to take it back-to-front. Thus Srb himself suggests that we should start by defining plasmagenes; he gives four points which say in effect that they are just like nuclear genes except that they happen to lie in the cytoplasm; and it is only in his fifth and last that he raises the "criteria and the experimental means for the detection of plasmagenes", which to my mind is a demure way of hinting that quite possibly no such entities as have been defined exist at all. I believe that a more useful method of discussion would be to start from the empirical facts and proceed cautiously towards the definition.

Prof. Srb's second paragraph does not persuade me to change my opinion that it is more difficult to account for a process of change (of cell-type during differentiation) in the face of two sets of persistent entities (genes and plasmagenes) than of only one set. As to the two quotations referred to in his third paragraph, they are both taken from p. 4 of Ephrussi's book. The two sentences which separate them rather tend to reinforce than to contradict the possibility that the persistence of differentiated cell-types is due more to irreversible nuclear changes than to cytoplasmic determinants; and they certainly do not refer to the tissue culture evidence, which in any case does not prove the point one way or the other.

I am glad to reiterate the point with which I ended my review. The great merit of Ephrussi's book is that, starting by an exposition of the arguments which have led many people to suggest that the idea of plasmagenes gives us a simple explanation of development, he comes at the end to advocate the more cautious and empirical approach. His discussion, in the Addendum to the main body of the book, of the criteria for the recognition of plasmagenes (to which Srb refers) is particularly valuable; but the whole progression of his thought is, as I hope I sufficiently emphasized, of the greatest interest, and makes his book one of outstanding importance in the history of these questions, which are among the most fundamental with which biology is concerned at the present time.

Are Inbred Strains Suitable for Bio-assay?

GRUNBERG¹ has directed attention to two properties of inbred strains which should counsel caution in their use for some experimental purposes: (1) They cannot be relied upon to remain constant in their heritable properties with the passage of time, and may diverge quite rapidly when split up into separate sub-strains and colonies. (2) They do not constitute phenotypically uniform material, but may, on the contrary, be strikingly more variable than the F_1 hybrids between strains.

This second proposition, for which Livesey² obtained experimental evidence in 1930, calls into question the established practice of using inbred material for the bio-assay of food factors, hormones, drugs, poisons, pathogens, etc. In such experiments precision in the estimates, and hence uniformity in the test organisms, is of the highest importance.

The characters measured in bio-assay are of the type usually termed 'physiological', whereas the

Exp.	Stock	Gm. 'Nembutal' per cent	Mean log response time	Antilog (min.)	Sum of squares	Degrees of freedom	Estimate of variance
I	Inbred	0.65	1.412	26	0.4896	13	0.0377
	F_1 hybrids	0.65	1.125	13	0.1827	8	0.0223
	"Mousery"	0.65	1.552	46	0.4853	13	0.0373
II	Inbred	0.65	1.593	39	0.8868	9	0.0988
	F_1 hybrids	0.85	2.110	129	0.2304	16	0.0150
	"Mousery"	0.65	2.185	153	0.5901	18	0.0453
Combined	Inbred				1.3784	23	0.0597
	F_1 hybrids				0.4231	24	0.0176
	"Mousery"				1.0744	26	0.0413

examples cited by Grüneberg all relate to morphological variation. None the less, the interpretation of the phenomenon advanced by Robertson and Reeve² and by Rasmuson⁴ would imply that we are dealing with a general biological law which must be expected to apply no less to 'physiological' than to 'morphological' characters. "The more heterozygous individuals," write Robertson and Reeve, "will carry a greater diversity of alleles, and these are likely to endow them with a greater biochemical versatility in development. This will lead to . . . a reduced sensitivity to environmental variations, since there will be more ways of overcoming the obstacles which such variations put in the way of normal development."

Two experiments on variation in a 'physiological' character have, in fact, just been published. Yoon⁵ has found in mice that F_1 hybrids are less variable in time of vaginal opening than the parental strains. Maynard Smith and Maynard Smith⁶ working with *Drosophila subobscura* have found a decreased variability in rate of development associated with heterozygosity for a marked chromosome.

We have recently conducted experiments with mice on the variation of a character chosen to be of the type measured in bio-assay, namely, the duration of narcosis following the intraperitoneal injection of 0.10 ml. per gm. body-weight of a dilution of a proprietary preparation ('Nembutal') of pentobarbital sodium.

We compared the variability in response of samples of three stocks of mice: inbreds from the *C57BL* strain, F_1 hybrids from *C57BL* ♀ × *C3H* ♂ crosses, and random-bred albinos supplied by "The Mousery", Rayleigh, Essex. Unfortunately, it was not possible to include a sample of the other parental strain (*C3H*). The duration of narcosis was expressed as the logarithm of the number of minutes elapsing from the abolition to the reappearance of the righting reflex. The logarithmic transformation was adopted in order to eliminate dependence of the variance upon the mean, and was found to be satisfactory for this purpose.

There were indications of differences in response both between the sexes and among different litters. In order to eliminate these sources of variation, the variances were estimated from the within-sexes within-litters sums of squares.

Two similar experiments were done on two separate occasions. On each occasion the three groups of mice were tested concurrently. In the second experiment, the hybrids were given a larger dose to compensate for their greater resistance to the drug. All mice were in the age-range 4-7 weeks, and those belonging to the same group in the same experiment were always born within the same eight days. The results of the two experiments were in substantial agreement, and are set out in the accompanying table.

It will be observed that the variance of the response is about three and a half times as great in the inbreds as in the hybrids. The difference is statistically highly significant, as judged by the χ -test ($P < 0.01$). In terms of a hypothetical bio-assay experiment, three and a half times as many of the inbred as of the hybrid mice would have to be used in order to obtain results of

the same accuracy.

More surprisingly, although the "Mousery" mice are as expected more variable than the hybrids, they are not more variable than the inbreds. On the contrary, the inbreds are more variable by half as much again. This difference, although not formally significant, should be regarded as suggestive, since the variability of the "Mousery" mice was almost certainly over-estimated in this experiment. It was not known which of these mice were litter mates. Hence the sum of squares used to estimate their variance includes a component which was eliminated in the analysis of the other two groups, namely, that due to differences between litters.

A more clear-cut indication that genetically heterogeneous random-bred mice may sometimes be less variable than inbred material was obtained as early as 1939 by Emmens⁷, who compared the variability of response to oestrone of a sub-strain of the *CBA* inbred strain of mice with that of a random-bred mouse colony. The variance of the inbreds, derived from the slope of the probit dosage-response curve, was about two and a half times that of the random-bred mice, and the difference was statistically highly significant.

Whether random-bred material is more or less uniform in a given case than inbred will, of course, depend upon circumstances which include the particular character which is measured and the genetical composition of the stocks which are compared. As regards the latter, the issue will be largely decided by the balance between the greater genetic variability among the random-bred organisms, making for phenotypic variability, and their greater heterozygosity, making for phenotypic uniformity.

The evidence suggests that the widely adopted policy of using inbred strains for bio-assay may be a mistaken one, and that inter-strain F_1 hybrids are to be preferred. Such material combines the genetic uniformity of inbred strains with the 'buffering' action against environmental variations which heterozygosity exerts.

We are in receipt of a research grant from the Agricultural Research Council.

Occurrence of *Chthamalus stellatus* (Poli) in Fair Isle and Shetland

THE Mediterranean/Atlantic littoral barnacle, *Chthamalus stellatus* (Poli), is at the northern limit of its range in Britain, and is confined to the south-west, west and north coasts. In the English Channel it is not recorded east of Swanage^{1,2} and Flamanville; but there are a few old records for two places far beyond these limits—at and near Heligoland (recorded several times during the nineteenth century³, but stated to be absent by more recent authors), and in the harbour at Anholt in the Kattegat (present March 1913, but absent in 1934⁴). The most northerly records to date are those for north-east Scotland⁵ (confirmed during 1951 by Dr. J. R. Lewis and me), where the species is finally represented only by sparsely scattered, but well-developed, individuals; Stephensen's record for "Norway, S. of Lofoten"⁶ would appear to be in error.

It is therefore of interest to record the presence of *C. stellatus* on the mainland of Shetland, as well as on Fair Isle, during June 1952; in all cases *Chthamalus* occurred above a belt of *Balanus balanoides*:

1. *Shetland* (June 24): *Chthamalus* scarce on the only exposed coast examined, in the south-west of the mainland (in Muckle Sound, just north of Spiggie Voe; position 59° 56' 46" N., 1° 20' 32" W.). Eleven of the larger barnacles were collected, and measured as follows: mean rostro-carinal length 7.6 mm. (range 4.8–10.0 mm.); mean breadth 6.7 mm. (4.5–9.5 mm.). Only three of these specimens were growing sufficiently close together to have been capable of cross-fertilization, and only these contained early-stage embryos.

2. *Fair Isle*: a number of coasts were examined, but *Chthamalus* was found only at the following two exposed places: (i) east coast (June 25)—scarce, at tip of headland (Landberg) on east flank of Mavers Geo (59° 32' 7.6" N., 1° 36' 22.5" W.). (ii) South-west coast (June 30)—frequent, on very exposed reefs south-west of South Lighthouse (59° 30' 50.7" N., 1° 39' 7.4" W.); twenty-six of the larger barnacles were collected, and nineteen undamaged specimens measured, as follows: mean length 9.0 mm. (range 6.1–11.2 mm.), mean breadth 8.9 mm. (6.0–12.2 mm.). Sixteen of the twenty-six barnacles contained developing embryos; the least developed were at a very early stage, but the most advanced were quite mature, measured 0.23 × 0.13 mm. (size of egg-case; mean of twenty-five from largest barnacle), with some ready to release nauplii.

The sizes of *C. stellatus* at these new northern limits of its range are comparable with the mean and maximum sizes attained in the Firth of Clyde (personal observations), the Isle of Man⁷, and Lancashire⁸, and with the largest mean sizes recorded near Plymouth (8.0 mm. mean diameter at an estimated age of four years)¹ and near St. Malo (6.3 mm. after three years growth in an exposed situation)⁹. The sizes of the largest barnacles suggest at least three or four years growth. Thus growth is not inhibited and there was no evidence of abnormal mortality or sterility of either young or old barnacles, such as might be expected if, as has been suggested by several authors, low winter temperatures were critical for survival of the species at the northern limits of its range.

These observations lend support rather to the view that the present over-all limits of distribution of

C. stellatus on British coasts are probably determined by factors affecting survival of the planktonic larval stages rather than of the hardy adult barnacles. In this respect it is of interest that at least some larvae in Shetland waters must have survived lower summer surface seawater temperatures (maximum in August 11°–18° C.) than are normally found anywhere else around the British Isles or throughout the North Sea¹⁰. Further, seawater temperatures off south-west England are normally higher from June to November than the Shetland August maximum, suggesting that both the reported failure of the early and late broods in the south-west¹, and the absence of *C. stellatus* east of Swanage, are due to environmental factors that are unfavourable for survival of larvae in some respect other than a direct temperature effect. These unknown limiting factors could be a shortage or absence of suitable planktonic food organisms at the appropriate time of year, and/or a generally unfavourable chemical environment (cf. the observations of Wilson¹⁰ on the poor survival of larvae of certain other marine invertebrates in Channel water as compared with Atlantic water).

Ants *Myrmica rubra* L. and *M. scabrinodis* Nylander as Intermediate Hosts of a Cestode

DURING recent ecological investigations of the ant fauna of heather moor in the west of Scotland, two of the commonest species in this region, *Myrmica rubra* L.¹ and *M. scabrinodis* Nylander, have been found to be acting as the intermediate hosts of a cestode. The cysticercoids lie freely in the body cavity and are extruded as soon as the cuticle is ruptured. They are ellipsoidal in shape (Fig. 1), measuring 530–700 μ by 340–400 μ , are very active and contain numerous calcareous granules. No suggestion of a cercarium has yet been seen. The larval scolex is often extruded very soon after the cysticercoid is removed from the ant and placed in saline. In most cases the scolex breaks away from the cyst, the rupture occurring at the base of the larval neck, and thereafter it progresses by movements of the suckers.

The dimensions of the scolex vary with the state of contraction; but in its relaxed condition it is approximately 300 μ long by 180 μ in diameter. The rostellar ring is 50–60 μ in diameter and consists

Fig. 1

of a double row of T-shaped hooks pointing outwards (Fig. 2), 13–16 μ in length and numbering about 180. The hooks of one row alternate with those of the other. The rostellum is invaginated in the scolex. The four suckers, 50–65 μ in diameter, are each armed with one compact row of hammer-shaped hooks 8–12 μ in length (Fig. 3). There are about 240 per sucker, all pointing towards the centre.

Fig. 2

Fig. 3

The cysticercoids have been found in males, queens and workers of both species, the infected ants being detected by an unnaturally dark chocolate coloration affecting the whole cuticle, compared with the dark reddish-brown tint of non-infected individuals. This colour difference may be due to the formation of a melanoid pigment from the excretions of the parasite. Estimates based on dissection of five hundred individuals, of both species, from those regions where the infection occurs suggest that at least 8 per cent are infected. Although the majority of infections consisted of a single cysticercoid, the number may be very much greater. The maximum observed was fifty from one *M. rubra* queen.

As regards the definitive host of this worm, an investigation has shown that the red grouse, *Lagopus scoticus scoticus* (Latham), of the regions examined carry heavy infections of the widespread grouse cestode *Raillietina* (*Paroniella*) *urogalli* (Modeer, 1790), the intermediate host of which is unknown. A comparison of the scolices of these worms and those of the ant cysticercoid suggests that they are identical in all respects; further, no infections have been found in ants from regions other than grouse-moor. Experimental proof of the identity of the cysticercoid is not yet available.

This appears to be the first recorded instance of the above two species of ant acting as the intermediate hosts of a cestode. M. F. Jones and M. W. Horsfall², in the United States, have given an account of *Tetramorium caespitum* L. as an intermediate host of *R. (Raillietina) echinobothrida* (Magnin, 1881), and Ch. Joyeux and J.-G. Baer, in France, mention *Tetramorium semilaeve* André³, also *Pheidole* sp.⁴, as transmitting the same worm. The latter authors further⁴

incriminate *T. caespitum* and *Pheidole* sp. as intermediate hosts of *R. (Raillietina) tetragona* (Molin, 1858), and *Formica rufa* L. as intermediate host of *R. (Raillietina) friedbergieri* (v. Linstow, 1878).

The investigation was financed by a Nature Conservancy grant to this Department.

Diurnal Rhythms in *Periplaneta americana* L.

In the cockroach *Blatta orientalis* there appears, in both laboratory experiments¹ and in natural infestations², a rhythm of activity under normal conditions of light and darkness taking the form of a burst of activity in the early part of the night, mainly before midnight, and a quiescent period in the later part of the night and during the day. This rhythm can be eliminated by keeping the insects under constant light, when activity becomes random; normal activity is, however, continued for at least three days under the new conditions. A similar rhythm occurs in *Periplaneta americana*³.

The type of carry-over of the rhythm under new conditions suggests that a hormone may be involved in the control of activity rhythms. Experiments have been performed in which two *P. americana* cockroaches have been joined together in parabiosis. The top cockroach, which had had the legs removed and was immobile, had previously been subjected to normal conditions of light and darkness and been found to have a normal rhythm of activity; the bottom, mobile cockroach had been left in constant light for its whole life and had no rhythm of activity. The activity of this parabiotic pair was then measured under constant light and they were found to have a rhythm of activity corresponding closely to that of the 'normal' top cockroach. If left in constant light over a period of six or seven days the rhythm was gradually lost. The reverse positions were also tested, the top cockroach having before parabiosis no rhythm, and the bottom mobile one a normal rhythm. The bottom cockroach continued to show a normal rhythm of activity.

Cloudeley-Thompson⁴ has shown that the light acts through the compound eyes and ocelli; painting over both causes a loss of rhythm. He also showed that decapitation caused a loss of rhythm, a feature which is well known in other insects where decapitation causes complete cessation of activity. Roeder maintains⁵ that the head ganglia exert a general control over locomotion. If this be so, the loss of rhythm after decapitation does not so much indicate the position of the controlling centre of the rhythm, as that there has been interference with the mechanism by which it is effected.

Two cockroaches which had been kept in constant light and had no rhythm were joined together, the eyes of the bottom mobile one painted over, and the pair placed in normal light and darkness. A normal

rhythm of activity was developed. After painting over the eyes and ocelli of both cockroaches of a pair in which the top one had no rhythm and the bottom mobile one a normal rhythm, the pair still showed a normal rhythm, but lost it in two days.

It would appear from the foregoing experiments that a secretion, carried in either the blood or tissues, is involved in the production of a diurnal rhythm of activity in the cockroach.

Work is proceeding on an investigation of the region forming the secretion.

Effect of Mineral Status on the Concentration of Rubber in *Hevea brasiliensis*

UNDER certain conditions, *Hevea brasiliensis* will respond to the application of fertilizers^{1,2}, which may give an increased yield of rubber per tree³. This increase is generally attributed to the enhanced growth and vigour of the tree, which consequently gives a greater output of latex. There is, however, no published evidence to show that the rubber concentration within the tissues can be influenced by the mineral status of the plant. The following describes briefly the main results of an experiment which bears on this point.

Seedlings of clone Tjirandji 1 were grown in sand culture under conditions of complete nutrient supply and also with a deficiency or low level of nitrogen, sulphur, phosphorus, magnesium, potassium, calcium, iron, manganese and boron. The plants were sampled four, five and seven months after sowing. The laminae were analysed for the mineral constituents while the stems and petioles were bulked together, dried, milled, extracted with warm benzene and the rubber in the extract determined after evaporation and alkaline hydrolysis⁴.

The values obtained for the total dry weight of shoot and roots per plant for the complete nutrient treatments were significantly higher than those of all other treatments with the exception of boron deficiency, which did not show a depression until the last sampling. The disparity between the complete nutrient plants and those of other treatments became more marked with time. Leaf deficiency-symptoms were observed in plants without, or with low supplies of, each of the elements except calcium and boron.

At the first sampling the 'complete nutrient' plants contained a significantly higher concentration of rubber in the stems and petioles than plants receiving other treatments. The decrease obtained in the boron-deficient plants was striking even though they did not exhibit leaf symptoms and appeared, visually, to be the most healthy and vigorous plants in the experiment.

At the second sampling, when the plants were five months old, the rubber concentration in the stems and petioles of the complete nutrient plants was still significantly higher than for the plants deficient in iron or boron. The rubber concentration was par-

ticularly low in the boron-deficient plants, which did not differ significantly from the complete nutrient plants in respect of dry weight per plant.

At the seven-month stage the dry weight yield per plant for each deficiency was significantly lower than for the complete nutrient plants. The concentration of rubber in the stems and petioles, however, generally exceeded that of the complete nutrient plants except for boron deficiency. It was apparent that whenever the dry weight yield per plant was low, the rubber concentration tended to be high.

Thus it was inferred that mineral status will only have a direct effect on rubber concentration in the earlier stages of growth when the yield differences between complete nutrient and deficiency treatments are relatively small. The gradual decrease in the rubber concentration observed with each successive sampling was probably due to the increasing proportion of non-latex producing tissue and the mode of expression of the results as a proportion of the total stems and petioles per plant. If it proves possible in future work to estimate the rubber in newly produced leaves or young tissues, a direct effect of mineral status on rubber concentration may even be obvious in old plants.

The concentration of the withheld nutrient in the laminae of the deficient plant was usually lower than that in the complete nutrient, although this was not always so for the sulphur- and iron-deficiency treatments.

The results demonstrated that nutrient deficiencies caused a reduction in the rubber concentration of the bulked stems and petioles in the earlier stages of growth only, before the differential effect of mineral treatment on yield response had become acute. The total rubber content of the plant was, however, governed by the dry weight production, which in turn was dependent on mineral status. Accordingly it must be expected, under field conditions, that where nutrient deficiencies are sufficiently severe to cause an appreciable decrease in the vigour and dry-weight production of the plant, a smaller yield of rubber per tree will result.

A fuller account of the experimental results will appear in the *Journal of the Rubber Research Institute of Malaya*.

Significance of the Ratio between the Water-soluble Aromatic and Nitrogen Constituents of Apple and Pear in the Host-Parasite Relationships of *Venturia* Species

VARIOUS workers have directed attention to the possible importance of aromatic host constituents in associations between plants and pathogens¹⁻³. Recent work at East Malling^{4,5} on the water-soluble constituents of apple and pear leaves and stems has made possible a detailed investigation of the biochemical aspects of host-parasite relations in *Venturia*

inacqualis and *V. pirina*, the causal fungi of apple scab and pear scab respectively.

Cultural studies have shown that the aromatic fraction of the water-soluble constituents (that is, the complex mixture of plant phenols extracted by ethyl acetate) and its separate main components may be strongly inhibitory to the growth and sporulation of the pathogen, depending on the complexity and amount of the nitrogen source. A high level of amino-nitrogen in the culture medium, for example, may result in complete degradation of the aromatic compounds by exogenous activity of a polyphenol-oxidase system secreted by the fungus. Conversely, an inorganic, or low-level amino-nitrogen, supply favours the inhibitory activity of aromatic compounds, resulting in all stages between reduction in sporulation and complete inhibition of growth. Marked differences in reaction to a given aromatic/nitrogen ratio have been observed between different clones of each pathogen.

By injection of inoculated apple and pear shoots with the aromatic fraction of leaf extracts, and urea, separately and in combination, evidence has been obtained of a similar mechanism operating *in vivo*. Using potted apple and pear trees under glass, shoots were enclosed in polythene-sleeve moist chambers as described by Stanton⁶ and inoculated by spray application of conidial suspensions. Injections were carried out during the incubation period of infection using a modification of the Roach method^{1,2} of petiole injection to ensure even permeation of the leaves on the shoot thus injected. Nine replicate leaves of similar age on nine shoots were used in each treatment, and disease expression was recorded by estimation of percentage cover by scab lesions on both leaf surfaces. The accompanying table is an example of the results obtained in a series of inoculation and injection experiments. Water injection had no effect on scab incidence as compared with uninjected shoots.

TOTAL SCAB (*V. inaequalis*, CLONE N.) IN EACH INJECTION TREATMENT ON COX'S ORANGE PIPPIN

Shoots injected with	Days after inoculation			
	14	18	21	28
Water	5.3	10.3	15.6	50.3
Cox aromatic fraction 1 per cent	0.0	0.1	0.1	3.3
Urea 0.5 per cent	17.0	47.2	61.2	102.1
Cox aromatic fraction 1 per cent and urea 0.5 per cent	23.1	24.3	31.6	54.3

Injection of the aromatic fraction of the constituents of Cox's orange pippin reduced infection markedly, while urea had the opposite effect. A mixture of this fraction and urea had no effect on the final level of infection as compared with water injection.

Mature leaves of all varieties are immune to infection. It was observed that injections produced their maximum effect on leaves approaching the mature resistant stage. It is thought that the aromatic/nitrogen ratio, at this stage of leaf development, can be most effectively altered by injection, as relatively small changes may inhibit or stimulate the pathogen. Work on the quantitative differences between young leaves of varieties characterized by varying degrees of resistance and between susceptible young leaves and immune mature leaves of the less resistant varieties is in progress.

It is suggested that the reaction of a clone of the pathogen to the aromatic/nitrogen ratio of the host

may be a critical factor controlling the level of pathogenicity observed.

A full description of these results will be given elsewhere.

Affinity of Sambucyanin for Nucleic Acids

I RECENTLY pointed out¹ the existence in *Sambucus nigra* berries of a dyestuff (sambucyanin) which can be used as a nuclear stain. Further investigations enabled me to ascertain that such a dye has a selective affinity for nucleic acids: actually, both deoxyribonucleic acid and ribonucleic acid are markedly coloured red *in vitro* by sambucyanin, the affinity for this dye not being shown by chemical and enzymatic hydrolysis soluble products of acids. Likewise, the stainability of cellular elements in tissues disappears after using specific nucleases.

Cytochemical demonstration of nucleic acids by means of sambucyanin is carried out, as a rule, on fixed material; however, it is possible to effect cellular element staining even supravitaly, using concentrated solutions. The best results are attained by using the dyestuff in the fresh state and avoiding fermentation. Purified pigment can be obtained from raw sambucyanin by means of salification with hydrochloric acid in methanol and precipitation of hydrochloride with sulphuric ether.

Staining method. (1) Dip sections of tissues (fixed in alcohol or formalin) in a 10 per cent aqueous solution of sambucyanin for ten minutes. (2) Wash in distilled water. (3) Operate a careful differentiation in 80 per cent alcohol in order to remove any aspecific dye adsorption on the part of other tissue elements (calcareous concretions, etc.). For a quick differentiation alcohol lightly acidified with acetic acid can be used. (4) Handle eventual contrast staining with a 1:1,000 aqueous solution of light green for about one minute. (5) Again rinse in distilled water. (6) Dehydrate in absolute alcohol, clear in xylol and mount in neutral balsam.

To carry out supravital staining, mix a 25 or 50 per cent sambucyanin solution with the specimen material suspended in neutral liquid in equal parts, and allow it to remain for some minutes before checking: nucleic acids become red.

Nucleic acid staining with sambucyanin affords, in comparison with other methods, higher sensitiveness and specificity; it gives a more constant effect and is easier to use, as well as offering the possibility of supravital use.

Alkaloids in Germinating Seeds of *Atropa belladonna*

DURING recent work on alkaloid biogenesis in *Atropa belladonna*, the results of which will be published elsewhere, we used James's method for demonstrating alkaloids in solanaceous meristems¹. This method is based on the formation of a red precipitate around a piece of plant tissue as a result of the diffusion of alkaloid in a potassium iodide-iodine solution (Bouchardat's reagent).

James tacitly assumes that the alkaloids demonstrated in germinating seeds are tropane alkaloids; but as Bouchardat's reagent is non-specific, there is insufficient proof for this.

Paper chromatography² of extracts of germinating seeds and seedlings of *A. belladonna* showed that the alkaloid which appears first is not hyoscyamine, or scopolamine, apotropine, belladonnine or tropine; but an unidentified, strongly basic alkaloid, which probably is belladadine, first isolated by King and Ware from Bulgarian *A. belladonna* root³.

Afterwards, scopolamine and then hyoscyamine appear.

Reversible Photo-oxidation of a Cytochrome Pigment in Photosynthesizing *Rhodospirillum rubrum*

THE investigation reported here is a continuation of experiments¹ on reversible changes in light absorption in purple bacteria induced by irradiation. It presents evidence which indicates that, in living bacteria in the absence of oxygen and in the presence of substrate, a cytochrome pigment is oxidized by illumination and is reduced in the dark. The bacteria used were vigorously growing, one or two days old, *Rhodospirillum rubrum*, strains 1 and 4. The growth medium for strain 1 was tap-water containing 1 per cent peptone, and for strain 4 tap-water with 1 per cent peptone and 0.5 per cent sodium chloride.

The apparatus for measuring the changes in absorption was a modification of the sensitive differential spectrophotometer described earlier¹. The change in absorption was brought about by illuminating a bacterial suspension with a beam of variable intensity, and the change was measured by means of a monochromatic scanning beam the wave-length of which could be varied. This scanning beam was at right angles to the actinic beam. It was too weak to cause a change in absorption. The source of actinic radiation was a tungsten lamp with a filter transmitting beyond 670 m μ .

Irradiation of a suspension of *Rhodospirillum rubrum* strain 1 in its growth medium under anaerobic conditions produced marked changes in absorption at about 430 m μ at

rather low actinic intensities. The original absorption was restored in the dark. These changes were complete in the time of the order of a second. The changes in absorption coefficients at different wave-lengths of a bacterial suspension produced by a constant actinic beam are plotted in Fig. 1. This curve we call the spectrum of the change in absorption. If the bacteria were suspended in 0.03 M sodium acetate plus 0.05 M phosphate buffer pH 6.8, under anaerobic conditions, instead of in peptone, a similar spectrum was produced by illumination, as measurements at a few wave-lengths indicated. A similar spectrum of the change in absorption was found for the more anaerobic strain 4 of *Rhodospirillum rubrum*, when measured in its growth medium.

At high actinic intensities a different spectrum of the change in absorption is found, the shape of which depends upon the intensity. This spectrum probably is a combination of the spectrum of Fig. 1 with another spectrum. The infra-red part of this other spectrum has been published earlier¹. The changes in absorption in the infra-red are probably due to changes in bacteriochlorophyll absorption.

The spectrum of the change in absorption of the *Rhodospirillum* suspension (Fig. 1) has a positive maximum at about 427 m μ and a negative one at about 409 m μ . Except for a shift of the maxima of about 7 m μ to longer wave-lengths, the spectrum of the change in absorption of the bacteria is similar to the spectrum obtained² by subtracting the spectrum of reduced cytochrome c from that of oxidized cytochrome c (Fig. 1, dotted line). This indicates that a cytochrome pigment is oxidized by a light reaction and is reduced by a dark reaction, as indicated by the restoration of the original absorption in the dark.

Van Niel³ provided evidence that the last step or steps of the photosynthetic dehydrogenation of the substrate in *Rhodospirillum rubrum* are the same as the last steps in the dehydrogenation of the substrate in the dark by respiration. The respiratory dehydrogenation presumably proceeds by way of a cytochrome system⁴. A cytochrome has been extracted^{5,6} from *Rhodospirillum rubrum* strain 1 similar in reducing properties to cytochromes c, but, unlike c, not oxidizable by cytochrome oxidase from pig heart⁵.

Although it is not yet possible to tell whether this cytochrome is identical with the cytochrome (Fig. 1) that is oxidized by irradiation, we may say that our experiments indicate that the photosynthetic oxidation of the substrate in *Rhodospirillum rubrum* is mediated by a cytochrome pigment.

Fig. 1. Spectrum of the change in absorption of a suspension of the non-sulphur purple bacterium *Rhodospirillum rubrum* strain 1 produced by a low actinic light intensity. Difference of absorption coefficient in the light and in the dark is plotted as a function of the wave-length of the scanning beam. The absorption coefficient of the suspension at 890 m μ , corrected for scattering, was 0.9. The figure shows also the difference of absorption spectra of pure oxidized and reduced cytochrome c according to Lundegårdh (ref. 2)

A detailed account of these and related experiments will be published elsewhere.

Composition of Bone and Muscle from the Lordotic and Normal Guppy, *Lebistes reticulatus*

The hereditary nature of an abnormality of the vertebral column has been established for at least two species of fishes: *Oryzias latipes*¹ and *Lebistes reticulatus*²⁻⁴. The biological nature of the mutation is fairly well understood; but there is a paucity of information concerning the chemistry of the bone and tissues from these mutant fishes, although Harrison⁵ found the total body calcium of lordotic *Lebistes* to be high. Further studies on the distribution of bone and muscle constituents from these fishes is the basis for this communication.

Mutant *Lebistes* were reared and maintained in the laboratory⁶ while normal fishes were obtained commercially. For study, the fish were killed in boiling water. After evisceration, the carcass was weighed, the spinal column was removed and cleaned of adhering tissue, and thoracic and lumbar muscle was obtained free of skin and scales. Analytical procedures were performed by methods previously described in detail⁷.

As shown in the accompanying figure, the log-weight of the vertebral column versus carcass weight is adequately described by an exponential equation for both the mutant and normal strains. However,

Weight of the spinal column versus carcass weight for lordotic and normal female *Lebistes*

Table 1. COMPOSITION OF THE VERTEBRAL COLUMN FROM MALE AND FEMALE LORDOTIC AND NORMAL *Lebistes**

	Lordotic	Normal	"t"†	P
Calcium	14.6 ± 0.30†	12.2 ± 0.43†	4.73	<0.01
Phosphorus	7.6 ± 0.18	7.2 ± 0.13	1.74	>0.10
Ca/P	1.93 ± 0.05	1.71 ± 0.05	2.09	<0.01
No. of determinations	23	22	—	—

* All values are expressed as the percentage of dry fat-free bone.

† Student's "t" value. From Snedecor, G. W., "Statistical Methods for Research Workers".

$$t = \frac{\bar{M}_1 - \bar{M}_2}{\sqrt{\frac{\sum x_1^2 + \sum x_2^2}{N_1 + N_2 - 2} \left(\frac{1}{N_1} + \frac{1}{N_2} \right)}}$$

$$\pm \text{Standard error} = \frac{\sqrt{\sum x^2}}{n(n-1)}$$

the slope of the line of regression calculated by the method of least squares is greater for the lordotic (3.25) than for the normal (1.58), and the correlation coefficient (P) is high.

The difference in bone weight is associated with a significantly greater concentration of calcium in the vertebral bone of the mutant fish (see Table 1); but the phosphorus concentration remains the same. These data are average values of bone obtained from both sexes since no significant differences between the sexes was apparent.

The lordotic mutation not only affects the anatomy of the vertebral column but also disturbs the anatomical arrangement of the thoracic and lumbar musculature⁴. However, various analyses of muscle tissue indicate no differences in chemical constituents between the two strains (see Table 2).

Table 2. COMPOSITION OF MUSCLE FROM LORDOTIC AND NORMAL FEMALE *Lebistes*

	Lordotic	Normal
Water (% wet weight)	77.7 ± 0.3* (14)	77.1 ± 0.4* (13)
Fat (% dry weight)	6.6 ± 0.7 (14)	4.0 ± 0.6 (13)
Protein† (% fat-free dry weight)	85.2 ± 0.9 (13)	85.0 ± 0.7 (12)
Calcium " " "	0.97 ± 0.06 (10)	1.03 ± 0.11 (13)
Phosphorus " " "	1.19 ± 0.05 (10)	1.29 ± 0.08 (13)
Ca/P	0.77 ± 0.03 (10)	0.80 ± 0.03 (13)

* Standard error.

† Protein was determined from nitrogen values × 6.25.

Numbers in parenthesis indicate number of analyses performed.

It is apparent from these studies that the lordotic mutation is associated with changes in the mechanism of calcification and formation of vertebral bone.

This investigation was supported in part by a grant in aid from the Society of Sigma Xi—Research Fund. I am indebted to Messrs. W. Schaumburg and J. Detrich, of Crescent Fish Farms, New Orleans, La., for normal fish and generous supplies of live fish food.

FORTHCOMING EVENTS

Monday, April 12

SOCIETY OF CHEMICAL INDUSTRY, CROP PROTECTION PANEL of the **AGRICULTURE GROUP** (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Fourth Annual General Meeting. Dr. R. A. R. Galley: "Some Pest Control Problems in the Colonies".

Tuesday, April 13

ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

ILLUMINATING ENGINEERING SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6 p.m.—Mr. H. M. Cartwright: "Illuminants for Colour Reproduction and Printing".

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. R. J. W. Reynolds: "Relation Between Chemical Constitution and Properties of Polymers".

ROYAL AERONAUTICAL SOCIETY (in the Library, 4 Hamilton Place, London, W.1), at 7 p.m.—Dr. H. Sutton: "Some Aspects of Modern Aircraft Materials".

Wednesday, April 14

ZOOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. R. W. D. Elwell: "The Lithology and Structure of a Boulder Bed in the Dalradian of Mayo, Ireland"; Dr. F. H. T. Rhodes: "The Conodont Fauna of the Keshy Limestone".

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Annual General Meeting. Mr. G. S. Bishop: "The Storage and Distribution of the Nation's Food".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (Grade III or II) in **PHILOSOPHY**—The Registrar, The University, Bristol 8 (April 15).

LECTURER (with good honours degree and teaching experience, and preferably other postgraduate industrial or research experience) in **PHYSICAL CHEMISTRY**, and an **ASSISTANT LECTURER** (with a good honours degree, and teaching experience) in **ORGANIC CHEMISTRY**, at Leeds College of Technology—Chief Education Officer, Education Department, Leeds 1 (April 17).

SENIOR ASSISTANT CHEMIST (preferably with waterworks experience, and a member of the Royal Institute of Chemistry, or with an honours degree in chemistry)—The General Manager, Bristol Waterworks Company, Telephone Avenue, Bristol 1 (April 20).

UNIVERSITY DEMONSTRATOR (with an honours degree in engineering, preferably combined with some agricultural experience) in **AGRICULTURE**—The Secretary, School of Agriculture, Downing Street, Cambridge (April 23).

WHEELER PROFESSOR OF BIOCHEMISTRY—The Registrar, University Registry, Oxford (April 29).

ADVISER OF STUDIES IN SCIENCE—The Secretary of University Court, The University, Glasgow (April 30).

ASSISTANT LECTURER, and a **TUTOR** in the **DEPARTMENT OF GEOGRAPHY**—The Registrar, The University, Liverpool (April 30).

MYCOLOGIST in the **PLANT PATHOLOGY DEPARTMENT**—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (April 30).

RESEARCH OFFICER (Physicist) (with an honours degree in science, or equivalent qualifications, and with research experience in the use of X-ray diffraction, preferably as applied to studies of the structure of proteins or high polymers) in the **BIOCHEMISTRY UNIT**, Wool Textile Research Laboratories, Commonwealth Scientific and Industrial Research Organization, Parkville, Melbourne, to participate in an intensive programme of research on the structure of wool and other fibrous proteins by chemical and physical methods—The Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 452/81 (April 30).

ENTOMOLOGIST (with at least a specialized degree normally involving a four-year university course, and preferably with a knowledge of botany and field ecology) in the **DEPARTMENT OF AGRICULTURE** (Tsetse Fly Operations Branch), Southern Rhodesia Government, for work which may embrace laboratory and field research or investigation on tsetse fly, field reclamation and survey work—The Secretary, Southern Rhodesia Government, Rhodesia House, 429 Strand, London, W.C.2 (May 1).

PHYSICIST or **METALLURGIST**, Research Officer or Senior Research Officer grade (Ph.D.), with additional research experience, or equivalent qualifications (essential), in the **DIVISION OF TRIBOLOGY** of the Commonwealth Scientific and Industrial Research Organization, at the University of Melbourne, for work concerned with problems of plastic deformation and phase transformation—The Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 370/81 (May 1).

PROFESSOR OF PHYSICS at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, May 1).

CHAIR OF PHYSICAL CHEMISTRY tenable at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 5).

RESEARCH OFFICER (with an honours degree in science, with biochemistry or chemistry as major subjects, and research experience,

preferably in some biological field) in the **PHYSICAL CHEMISTRY**, **STATION**, Division of Industrial Chemistry, Commonwealth Scientific and Industrial Research Organization, Fishermen's Bend, Victoria, Australia, to participate in a programme of research on the fixation of nitrogen by biological systems—Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 590/447 (May 6).

SENIOR RESEARCH OFFICERS (3) (preferably with specialized post graduate training in a branch of science applied to agriculture, for example, plant physiology, soils, crop husbandry or agricultural engineering) to take charge of sugar cane research in the main ecological divisions of the sugar area—The Director of Research, Sugar Manufacturers' Association of Jamaica, Ltd., Sugar Research Department, Mandeville, Jamaica, British West Indies (May 7).

LECTURER IN GEOGRAPHY at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (May 10).

DEMO STUDENT (with an honours degree in chemistry or engineering) in **CHEMICAL ENGINEERING**—The Registrar, Imperial College of Science and Technology, London, S.W.7 (May 14).

PROFESSOR OF MECHANICAL ENGINEERING, and a **PROFESSOR OF CIVIL ENGINEERING**, at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, May 15).

ASSISTANT LECTURER (preferably with special qualifications in stratigraphy and paleontology) in **GEOLOGY**—The Registrar, University College of South Wales and Monmouthshire, Cathays Park Cardiff (May 20).

LECTURER (with a good honours degree in botany, and research experience, preferably in genetics) in **BOTANY**, at the Imperial College of Tropical Agriculture, Trinidad, British West Indies—The Secretary, The Imperial College of Tropical Agriculture, 40 Norfolk Street, Strand, London, W.C.2 (June 30).

LECTURER (with knowledge of industry, and preferably with a knowledge of latex) in **RUBBER TECHNOLOGY**, a **LECTURER** (chemist or physicist, preferably with some practical experience) in **PLASTICS TECHNOLOGY**, and a **LECTURER IN PHYSICS**—The National College of Rubber Technology, Northern Polytechnic, Holloway, London, N.7.

MASTER TO TEACH BIOLOGY to University Scholarship standard—The Headmaster, Haberdashers' Aske's Hampstead School, Westbere Road, London, N.W.3.

SCIENTIFIC OFFICER (Physicist) (with first- or second-class honours degree in physics, with mathematics as subsidiary subject, or equivalent qualifications) in the Department of Scientific and Industrial Research, Water Pollution Research Laboratory, Stevenage, for research on physical problems arising in the study of polluted rivers—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A86/54A.

SCIENTIFIC OFFICERS (with first- or second-class honours degree, or equivalent, in physics or mathematics) with the Air Ministry, for operational research on a wide variety of problems, in London and the provinces, under the direction of the Scientific Adviser to the Air Ministry—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.86/54A.

SENIOR EXPERIMENTAL OFFICERS (Ref. 566), **EXPERIMENTAL OFFICERS** (Ref. 567), and **ASSISTANT EXPERIMENTAL OFFICERS** (Ref. 568) (with at least H. S. C. in science subjects) in the **DEPARTMENT OF ATOMIC ENERGY**, Culworth, near Warrington, for duties connected with analysis of materials arising in research on metallurgical and chemical processes involving rare metals—The Department of Atomic Energy, Industrial Group Headquarters, Risley, Warrington, quoting appropriate Ref. No.

A short history of graticules—No. 3

Kings of diamonds

In his book *Oculus artificialis teleiopltricus*, the optician Zahn writing in 1685 suggested the marking of glass discs with a diamond to replace micrometers of silver wire, hairs, or silk used hitherto. There is, however, some doubt as to the date of this work, which may have been 1702.

In 1700 La Hire also suggested that a greatly improved cross-wire could be obtained by ruling with a diamond on a glass disc. Whether Zahn's or La Hire's suggestion came first is doubtful, but it can be said that the resultant diamond-ruled glass disc was the first successful graticule as known to-day. La Hire described graticules ruled on glass with 13 horizontal and vertical lines, and with 6 concentric circles both of which would make patterns in current use in microscopy to-day.

TWO SHILLINGS

THE *Newton*

LONG WORKING DISTANCE ATTACHMENT

... provides a working distance of 12.8 mm. between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm. objective.

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

Member of the A.E.I. Group of Companies.

High vacuum equipment

As high vacuum technique becomes more widely used in industrial processes, research work employing high vacuum equipment assumes an importance ever greater than before. Metrovick has always occupied a leading position in the research and development of apparatus dependent in some degree on high vacuum technique, e.g. X-ray apparatus, electron microscopes, vacuum coating plant, linear accelerators, cyclotrons, vacuum furnaces, etc. Complete vacuum equipments for the laboratory and the factory, as well as individual items such as vacuum pumps, valves, gauges, etc., are made by:

**10⁻⁶ grams of MOISTURE
is a very small amount . . .**

Micro-quantities of moisture present the biggest problems to research processes dependent on properly dried materials, and the simplest answer to these problems is the EDWARDS MICRO-MOISTURE DETERMINATION UNIT—a highly accurate and reliable instrument which was developed in connection with extensive research by Edwards into freeze drying techniques.

The adoption of this robust unit means there is no degradation of materials . . . that the specimen temperature can be finely controlled . . . moisture determinations down to 10⁻⁶ grams can be achieved . . . and, finally, only one specimen weighing is required.

The **NEW** Muirhead-Wigan decade oscillator

TYPE D-650-A

THIS precision laboratory oscillator, which covers a range of 1 to 111,100c/s with an overall frequency accuracy of $\pm 0.2\%$ or $\pm 0.5\text{c/s}$, employs the decade tuning system, by means of which the frequency can be set quickly and accurately on four decade dials and a range switch. This system of tuning ensures the highest possible frequency accuracy and stability. It also enables a given frequency setting to be repeated exactly, and permits the addition or subtraction of a fixed number of cycles per second, thus giving an incremental accuracy of an extremely high order. No other type of oscillator possesses all these advantages.

FEATURES

Frequency range: 1-11,110c/s and 10-111,100c/s.

Frequency accuracy: $\pm 0.2\%$ or $\pm 0.5\text{c/s}$.

Hourly frequency stability: $\pm 0.02\%$ over most of range.

Maximum output:

2W into 8000 ohms above 20c/s.

50mW into 8000 ohms below 20c/s.

Harmonic content: 1% at 1W output.

Hum level: -80db relative to maximum output at 1000c/s.

Power supply: 200-250V, 50c/s; 90W. or 95-125V, 60c/s; 90W.

Dimensions: 17½ in. wide x 10½ in. high x 13 in. deep.
(43.8 cm x 26.7 cm x 33 cm).

Weight: 83 lb. (38 kg).

UTILIZATION OF SCIENCE BY INDUSTRY

THE view that new scientific and technical knowledge is absorbed into certain sections of British industry too slowly, and that a scientific approach to the day-to-day problems of production and organization is less common than it should be, is widely held. It was emphasized by Sir Henry Tizard in his presidential address to the British Association more than five years ago, and it has since been accepted by the Advisory Council on Scientific Policy and found some support in the reports coming from the productivity teams of the Anglo-American Productivity Council. It was subjected to detailed analysis by Dr. R. L. Meier in his paper "The Role of Science in the British Economy" and, although in some quarters this view is regarded as mistaken, the Manchester Joint Research Council was fully justified in accepting it for the purpose of its inquiry into the relations between science and industry in the Greater Manchester area*.

This inquiry, carried out in the main by a team of three investigators, guided by a Steering Committee, during 1950-53, was not primarily concerned to discover whether this opinion is right or wrong. The investigators were interested rather in examining the reasons usually given for the alleged backwardness of British industry in this respect. The inquiry was limited to some 225 firms each employing more than fifty persons in an area of south-east Lancashire from Blackburn and Burnley to Stalybridge, Stockport and Altrincham. Some 76 per cent of the firms approached responded, and in the textile industries 20 per cent of the establishments in the area were eventually visited; in the engineering industries 17 per cent of the firms were visited; in the modern industries group, concerned with the manufacture of materials or articles unknown to society or industry a century or even fifty years ago, 22 per cent were visited; and of those in miscellaneous industries, 23 per cent.

In presenting this report, therefore, the Manchester Joint Research Council believes that the facts recorded are sufficiently representative to give a reliable basis for tentative conclusions as to the answers to some of the leading questions which at once arise out of any assumption as to the backwardness of British industry. Sometimes, for example, this is attributed to the relatively small number of scientists employed in industry, or to the absence of men of the right type or appropriate training. Alternatively, it is argued that industry does not make the best use of the scientists it does employ, or that the alleged backwardness is due to weaknesses in the organization of research and development and in their relation to production; or again, that the lack of scientific enterprise in industry is due to government control, to restrictive practices by management or labour, or to the general level of taxation.

* Industry and Science: a Study of their relationship based on a survey of firms in the Greater Manchester Area carried out by the Manchester Joint Research Council, 1950-1953. Pp. viii+188. (Manchester: At the University Press, 1954.) 12s. 6d. net.

On the validity of these last arguments, the report expresses no opinion; but, with this exception, the Steering Committee organized its inquiry so as to throw as much light on the questions that immediately arise out of the foregoing criticisms. Without expecting that the inquiry could by itself provide a conclusive answer to the arguments, it sought, for example, to accumulate facts which would, at any rate indirectly, indicate whether employment of scientists led to a progressive atmosphere and whether the presence of scientists at the higher levels of management or on the directorate made any crucial difference in the attitude or practice of the firm. In the same way, the relations between the universities and the research associations were examined so as to throw light on the question whether directly or indirectly they provided sufficient basis for all requirements, or whether there was a need and demand for new institutions. Next, light was sought on the respective roles in industry of the universities, the research associations and the research departments, their interrelationships, and the role of research and development departments in the firms themselves and the relation of these departments to other branches of the firm. These questions, moreover, are related to the earlier questions about the employment of scientists in industry, and the investigators sought specifically to throw some light on these relations between the use of scientists in industry and problems of organization and institutions.

Although the inquiry covers but a small sample of industry in Britain, it touches a wide range of problems, and the facts recorded are a useful contribution to the current discussion of such varied topics as scientific man-power and higher technological education, education for management, the functions of the research associations, the relations between universities and industry, the work of the National Research Development Corporation, information services and the like. It is less searching and exhaustive in its treatment of the research associations than either Prof. R. S. Edwards's study, or the particular analysis of the work of the British Leather Manufacturers' Research Association which the Department of Scientific and Industrial Research made three years ago; but the important questions are nevertheless asked, and at least some indication given as to where the answers lie. Moreover, the ultimate value of the survey may well lie in its firm warning against facile generalizations. Generalizations covering the whole field of British industry regarding the use which is, or should be, made of scientists and technologists may be wholly unjustified.

Although there is no uniform pattern; however, the information collected affords fairly solid grounds for the belief that the extent to which industry in Britain makes the maximum use of the possibilities for scientific assistance depends directly on the outlook of the management at the head of each particular firm. The investigation revealed no evidence that scientists are, to any material extent, wastefully employed: there is no reference to wasteful employment practices, particularly in the engineering field,

that result in inefficient utilization of professional man-power, such as are deplored by the National Man-power Council in the United States in its report, "A Policy for Scientific and Professional Manpower", and have also been noted there by the American Society for Engineering Education and the National Society for Professional Engineers. Even if, on the contrary, there is no real justification for the belief that in Britain a shortage of scientists is the basic cause of any existing backwardness, difficulties in recruiting a really adequate supply of scientists for industry—of which the investigators noted some signs—are likely to discourage any failure to make the best possible use of those actually employed.

The dominant impression left by this study is that the attitudes of those directing the firms consulted is the decisive factor. Such changes as have come about in the past decade or two are the result of a changed 'climate' of thinking in the highest management circles. To that extent the inquiry confirms all that Dr. K. T. Compton said as to the importance of this climate of opinion in his address to the Parliamentary and Scientific Committee at its annual luncheon on February 18. The importance of higher technological education is very far from being limited to its direct effect on the supply of scientists or technologists: its influence permeates widely into society, and helps to develop the industrial and social climate in which technological progress and productivity can thrive.

It is worth noting in this connexion that the investigators found a surprisingly high proportion of science graduates occupying seats on boards of directors. Out of a total of 684 graduates employed in the firms visited, 93 were directors; and these were distributed over 70 of the 99 firms which were found to be employing graduates. Moreover, 74 of these graduates had reached this level by their own efforts, unassisted by family associations, but by way of positions involving day-to-day contacts with the firm's industrial, as distinct from purely research, activities. That position is perhaps more encouraging than might have been expected; but if in a high proportion of these firms direction of policy lies to some extent in the hands of scientifically trained men, the inquiry left the definite impression on the investigators that for those firms without qualified staff, as a whole, the services of a trained scientist or technologist capable of undertaking skilled supervision of processing efficiency would usually have been of real value.

The investigators recognized very clearly that no general criterion of satisfactory use of science in industry is available. Conditions vary too widely for any common standard to be applicable, and this to some extent must apply also to the nature and extent of the research conducted by a particular industry. That has its bearing on the work and functions of the research associations; and while the survey emphasizes the importance of the contribution of the research associations, it directs attention at the same time to the limitations of the research association movement and of the part the research associations can be expected to play in furthering

the use of science in industry. It is generally believed that, within their limitations, the work of the research associations is well done and is appropriate to the industry concerned. Such associations even now, however, do not cover the whole of industry, and the report suggests that they might with advantage increase their technical contacts with their member firms.

Too much must not be made of an investigation which at best is only a sample, and in which no scale of comparison elsewhere is possible. Nevertheless, the findings of the Manchester Joint Research Council, even though they rest on the personal judgment and experience of the investigators, suggest that any considerable expansion of the research association movement in Britain is a matter for careful forethought. No such expansion on the scientific research side is suggested in this report; but rather, increased effort in the technological and liaison work. The hope seems to be that by fostering a scientific outlook within the member firms, there may be a more effective application of existing knowledge and, apart from a better use of the facilities which research associations already provide, even a wider prosecution of research within the firm itself. The investigators seem to have no doubt in their own minds that such research is by far the most effective, however much it may draw on existing fundamental knowledge accumulated co-operatively in the research associations or at the universities.

A further encouraging feature of British industry revealed by this report is a much wider and closer contact with the universities than had been expected. This contact occurs in dealing with scientific or technical problems arising in actual production, where some new technique or particular experience available at the university may help to resolve a difficulty, rather than from consideration of the broader problems of training, recruitment or management research such as have formed the subject of conferences arranged between the Federation of British Industries and the universities. Nevertheless, it is true that more and better liaison is still required, and that there are ways in which the universities can assist in the further training of those who have already entered industry. However, the inquiry has revealed that immense resources of science are still untapped by industry and that more bridges between industry and science and greater mutual respect between the two are still prime needs in Britain; it has equally demonstrated that in certain fields British industry has most effectively enlisted already the resources of science. The investigators are right to condemn the unwarrantable depreciation of our achievements in discussing the use which British industry makes of science, with the attendant lowering of national prestige and discouragement of the coming generation of scientists and industrialists.

On the whole, the survey affords little support for the view, pressed rather strongly by Mr. John Edwards in the House of Commons at the second reading of the Development of Inventions Bill, that the resources of Great Britain are so distributed as to cause a lack of balance between those devoted to

fundamental research and those devoted to development. Mr. Edwards did not advocate any reduction in fundamental research, and neither does the present report; but the latter suggests that more effective channels of information rather than any considerable increase of development is the primary need. The functions of the National Research Development Corporation as a provider of risk capital, in any event, lie outside the limits which the Manchester investigators deliberately set themselves, and their comments on the activities of the Corporation are limited to the strong suggestion that the Corporation is not yet sufficiently widely known to play effectively the part it was created to fulfil.

How important or permanent that part may be is unlikely to be indicated by studies such as that which has just been carried out by the Manchester Joint Research Council. We need to know more as to the causes of relatively slow development in some sectors of British industry before a sound judgment is possible here. Light is likely to come from the detailed study of a few selected major research and development projects in which Britain is regarded as having lagged behind. Such an analysis, moreover, must take full account of those fiscal factors and restrictive practices which were excluded from this survey, and on which Sir Henry Tizard commented forcefully in his Messel Memorial Lecture a year or two ago. Financial and fiscal policies in themselves can easily form a climate of opinion, and encourage or discourage practices both on the part of employers and employed which are inimical to enterprise and the vigorous and uninhibited development of new ideas.

Few, if any, new ideas emerge from this report. It affords, so far as it goes, a notable amount of support for the existing structure for the organization of research in Britain, and shows very clearly that decisions to expand any particular sector should be taken not in isolation but in the light of full consideration of other claims on the country's resources, and in the light of the effect upon other sectors. For example, little interest was evinced in sponsored research; but the investigators suggest that there might be room for an institution of this character to work in the limited fields of chemical and electrical engineering. The major task, especially where industry is not yet making full use of science, is one of education. What aid science can bring to many branches of industry has not yet been expounded adequately from a point of view calculated to convince the ordinary business man. Liaison and education are needed to a far greater degree than more and better science.

The implications of this situation are not fully explored in this survey, nor indeed could they have been. There is evidence enough, to which reference has already been made, to suggest that we can await with some confidence the outcome of the slow process of persistent liaison and education from both sides, which the investigators themselves recognize as the policy likely to secure the best results, rather than a single act of policy either in the field of education or in industry. That, however, is an additional reason for

pressing forward, with more urgency than the Government has yet displayed, with the expansion of higher technological—as well as of technical—education, and with the formulation of a policy which gives full expression to the respective contributions of the universities, the colleges of technology, the technical colleges and the research associations themselves.

In that context the expansion of the research associations is likely to proceed in step with their appropriate place in the educational structure as well as the research organization of industry, and in providing that greater flow of information to industry not only from such bodies but also from the Department of Scientific and Industrial Research, the National Research Development Corporation and all those other varied sources of new knowledge such as the universities, the learned societies and the independent research institutions. The freer and fuller flow of information can contribute to the formation of a climate of opinion which both favours the acceptance of new ideas and the recruitment into industry of those competent to appreciate the significance of new knowledge and to apply it. "The ultimate responsibility for the use of scientific knowledge, as for the introduction of any sort of new idea, lies with the board of directors and the top level of management of each firm. The personalities of such men, and their attitudes to the scientific approach to their production, is therefore a matter of predominating importance." Any shortcomings of British industry in this respect are unlikely to be removed swiftly; but on the evidence of this report the whole trend is towards a position in which—except in firms whose routine activities involve little need of scientific knowledge—it will become increasingly rare to find in industry boards of managers on which no scientist finds a place.

THE BRITISH CONTRIBUTION TO MEDICINE

The British Contribution to Medicine

By Dr. Jaime Jaramillo-Arango. Pp. xii+220+45 plates. (Edinburgh and London: E. and S. Livingstone, Ltd., 1953.) 25s. net.

BEFORE entering the diplomatic service, Dr. Jaime Jaramillo-Arango was an eminent surgeon in the Republic of Colombia. He spent the period of the Second World War first as minister and then as ambassador of his country in Great Britain, and as a lasting souvenir of his mission and a tribute of admiration to the war effort of "this great nation", he decided to write an account of the "British Contribution to Medicine". The book was written in Spanish primarily for the benefit of medical men in the Latin-American countries. It must be a matter of surprise to the British reader how Dr. Jaramillo-Arango as an ambassador could have made himself so familiar with the details of much modern British medical research, as is apparently the case. This is where the attractive introduction written by Sir Arthur MacNalty is so useful, for it explains how closely the author entered into the life of medicine

in Britain, and not only visited universities, hospitals and laboratories but also attended medical and scientific societies and became friendly with many leaders of British medicine. There is good evidence in the book of these friendships in the descriptions of the life-history of some of the discoverers, which could only have been obtained from the individuals themselves. Personal knowledge of the research workers has also added greatly both to the factual account of the work described and to its interest, and has generally led to a better-balanced history of the work. Where the author seems to have had little or no contact with the active research workers in a particular field, as in the case of nutritional diseases, the account given is not quite so interesting and does not have the stamp of one so familiar with the subject.

Dr. Jaramillo-Arango picks out six medical discoveries of the past fifty years which he regards as almost exclusively the achievement of British medicine. These are anti-typhoid-paratyphoid inoculation, the discovery of penicillin, the role of the mosquito in the transmission of malaria, the discovery of paludrine, the discovery of vitamins, and the synthesis of stilboestrol.

The various chapters are written around these discoveries. Sometimes, as in the case of typhoid inoculation, penicillin, and the part played by the mosquito in the transmission of malaria, each British discovery forms a major part of a chapter. In others, the British work is rightly treated as an incident in the discussion of much wider problems; thus, the discovery of stilboestrol and, later in the United States, of its alleviating effect in cancer of the prostate, is placed in a comprehensive account of carcinogenesis and of the attempts to find curative agents of cancer. In this chapter, as might be expected, attention is given to the well-known work of Kennaway and Hieger and their colleagues at the Royal Cancer Hospital on the isolation of highly carcinogenic substances from tar.

It would be wrong to assume that British contributions even where, as in the case of penicillin, they dominate the picture, are allowed to monopolize any particular advance in knowledge. The author has endeavoured to place each major discovery in its proper setting. For example, in the chapter headed "The History of Antibiotics" all the salient discoveries are discussed, starting with Pasteur's observation in 1877 in which he showed the antagonism between the anthrax bacillus and the common aerobic bacteria, and finishing off with the most recent discoveries of terramycin and erythromycin. Detailed references are made to many outstanding figures who have participated in the development of knowledge in each field, and no limit in time or nationality excludes the mention of individual discoveries. Indeed, even experts in medical research will occasionally be surprised to read of unknown or forgotten observations and discoveries made in the past and in other countries concerning subjects of great current interest.

The book is well worth the attention of both the general reader with some basis of scientific knowledge and of the medical man. After all, it deals with a subject which has transformed human existence throughout the world during the past hundred years, and from this point of view challenges in importance any other scientific advance. Secondly, it is attractively written and can be read with much pleasure. It also gives an opportunity of seeing how well, in

the restricted field of medical research dealt with, British contributions stand in the eyes of a distinguished foreigner. To the British research worker it must afford an unusual experience of seeing some of the fruits of modern medical research in his country receiving adequate appraisal when placed in an international setting. The fact that the book was written primarily for foreign eyes gives it a special value as evidence of the high standing of our medical research. We owe a great debt of gratitude to Dr. Jaramillo-Arango for having undertaken this imaginative tribute to Great Britain, and in return must express our real appreciation of his scholarly and interesting book.

SCIENCE IN CRIMINOLOGY

Medical and Scientific Investigations In the Christie Case

By Dr. Francois E. Camps. Pp. xxiii + 244 + 6 plates. (London: Medical Publications, Ltd., 1953.) 30s. net.

RELATIVELY few criminal cases afford the opportunity for any extensive exercise in the forensic sciences. R. v. Ruxton and R. v. Haigh offered much in reconstruction data for identity, and R. v. Dobkin had the added interest of dental detail of exceptional quality and of evidence as to the cause of death. The recent case of R. v. Christie has renewed interest in these problems—in methods of ageing, sexing and height estimation in human remains, in the detection of a cause of death after a long interval of time, and the ever-difficult problem of determining the lapse of time since death. It also provided another problem—how to present such evidence at court in the most easily assimilable form: science must be made both reasonable and palatable to lay juries.

This record by Dr. F. E. Camps of the evidence in R. v. Christie is not so much his work as that of a team of experts whose specialities—microscopy, analytical chemistry, mycology, dental histology, anatomy, radiology and Dr. Camps's own forensic pathology—combined to forge the links in the evidence presented by the Crown for the prosecution in corroboration of the statements of admission of guilt made by the accused. Like all edited books, it lacks a uniformity of style and reveals both talent and mediocrity in prose-writing. It is in the content of scientific data that its chief attraction lies.

The most polished pieces of work are undoubtedly those of Prof. A. E. W. Miles on the study of the teeth and of Dr. Richard Harrison on the anatomical problems of sexing, ageing and giving stature to the skeletal remains: each is excellently illustrated and well tabulated. Gustafson's modern 'points method' for ageing teeth and of using incremental patterns to assign them to individuals receives some further support, and the superiority of the formulae of Trotter and Gleaser for stature-estimates over the older Rollet, Pearson or even Dupertuis and Hadden formulae is amply reflected: older tables all showed a tendency to under-estimation. Incidentally, it is to be noted that neither Dr. Camps nor his dental advisers seem to have read the descriptions of 'pink teeth' in the dead by both Thomas Bell in 1829 or of his pupil, the famous Tomes, for they study at some length the nature of the 'new observation', now more than a century old; little, indeed, is new when one comes to search the literature.

A chapter on the known facts of coal-gas absorption factors by the Gas Board expert, F. O. Smith, tends to elaborate somewhat tediously the standard writings on the subject; but one must remember that this book is plainly intended for interested lay consumption as well as medical and scientific. Major H. A. Dade records the surprisingly restricted mycological findings of the intact bodies—almost entirely of common and ubiquitous moulds—*Mucor racemosus* Fresen, *Penicillium cyclopium*; it would have been of interest to have recorded the temperature-ranges for growth of these moulds.

The book is completed by the addition of Christie's three statements, which afforded a great deal of 'testing evidence', and of a short account of the Scott Henderson inquiry which followed public outcry over the prior execution of Evans who had lived with Christie at a material time.

Anyone interested in the application of scientific knowledge to the needs of the law in criminal investigation will find much of interest here: it is a good example of the demands for team-work which occasionally arise in the course of a practice in forensic medicine and criminology, and Medical Publications, Ltd., have made an excellent job of reproduction and illustration on first-class paper. It is not to be recommended to the amateur sleuth, the writer of detective thrillers or the morbidly curious, for it is a serious scientific account of laboratory and field-investigations.

KATH SIMPSON

POISONOUS PLANTS OF INDIA

Poisonous Plants of India

Vol. 1. By Sir Ram Nath Chopra, Rattan Lal Badhwar and Prof. Sudhamoy Ghosh. (The Indian Council of Agricultural Research: Scientific Monograph No. 17.) Pp. liv + 762. (Delhi: Manager of Publications, 1949.) 30 rupees.

ALTHOUGH the title-page is dated 1949, this book has only recently appeared after a 'labour' which has lasted about fourteen years. The manuscript was sent to the press at the beginning of the Second World War; but owing to vexatious delays due to shortage of paper, and for other reasons, the first volume did not leave the printers' hands until 1949. Shortly after it appeared, the volume was recalled for some correction and has only lately been issued to the public. The welcome which it is sure to receive will be some recompense to the authors for their frustration.

In their preface the authors state that it is their aim to survey the whole field of poisonous plants in India from the botanical, chemical, pharmacological and economic angles. This aim has been achieved; but it is open to question whether it would not have been better to exclude a great deal of the botanical matter. Botanists who use the book will not be interested in the botany as such, for which they have other sources, and non-botanists will only be interested in the plants and their products.

This is only a trifling criticism; but the size of the book might have been considerably reduced without sacrificing any of the really important matter in it—which is undoubtedly the account of the poisonous products contained in the tissues of the plants themselves. The information given on this subject is thorough and reasonably up to date, although much work on poisonous drugs found in

Indian plants must have been done since the manuscript of the book went to press fourteen years ago. The authors, in their desire for completeness, even go so far as to describe the symptoms and treatment of persons suffering from poisoning.

Although a great deal of information is given about a large number of species, it is surprising to note the number of plants which are "reported" or "said" to contain poisonous principles, and upon which no work has yet been done. This is a measure of the task which lies before Indian chemists and pharmacognosists during the years to come.

The book is illustrated by a number of line-drawings of very unequal merit. Some of them are reasonably good, while others are quite unworthy of a book of this importance: some are from works fifty years old, while others have come from books published a hundred or even a hundred and fifty years or more ago. A serious defect in the illustrations is that in no instance is there any indication of the size of the parts illustrated, or even what these parts may be, although a number of the blocks contain dissections. If it is thought necessary to have illustrations, then these should be good. The binding is quite inadequate for a book of this weight (4 lb.) and will definitely not stand up to the very frequent occasions on which the volume will be consulted.

The authors are to be congratulated on a really useful book, which for many years to come will be indispensable to all medical and botanical libraries as a work of reference.

N. L. BOB

TURBULENT MOTION OF FLUIDS

The Theory of Homogeneous Turbulence

By Dr. G. K. Batchelor. (Cambridge Monographs on Mechanics and Applied Mathematics.) Pp. xi+197. (Cambridge: At the University Press, 1953.) 25s. net.

TO obtain some understanding of the 'turbulent' motion of fluids (a term first used by Kelvin) has been one of the outstanding problems of the physical sciences since 1883, when Osborne Reynolds initiated the subject in a series of brilliant papers. In the succeeding age, when the problems most discussed by physicists were on the atomic and sub-atomic scale, the problem of turbulence remained a notable exception and continued to excite the imaginations of the most eminent students of the physical sciences. Werner Heisenberg, for example, has constantly returned to the subject from his better-known researches in quantum theory, and Rayleigh, Sommerfeld and Kolmogorov all made contributions. Ludwig Prandtl, the creator of the modern dynamics of fluids, who died recently, and his pupil von Kármán, have been important influences at all stages of the work. But perhaps the most single-minded, and successful, of the many warriors assailing the dragon has been G. I. Taylor who, though approaching his seventieth birthday, is still extremely active in the fight. After tackling the problem from many different and valuable points of view, he initiated in 1935 a new approach. Recognizing at last that all the methods based on the conventional ideas of statistical mechanics were doomed to failure, he developed a statistical theory of turbulence founded on the recognition that fluids behave like continua, with the statistical correlation coefficient between the fluid velocities at two nearby

points as the fundamental observable. Later he demonstrated the relation of this correlation to the spatial spectrum of turbulence.

The new methods have been applied principally to the particular case of 'homogeneous' turbulence—that is to say, turbulence the statistical properties of which do not vary from point to point. The difficulties of extending them to non-homogeneous turbulence appear formidable; but the qualitative ideas suggested by the statistical theory, and wind-tunnel results, for homogeneous turbulence are already useful in all problems of turbulence. Since the Second World War, progress in homogeneous turbulence has been nowhere so great as in Taylor's own research group in the Cavendish Laboratory, Cambridge, led by G. K. Batchelor and A. A. Townsend. In the circumstances, no one could have been more suitable than Dr. Batchelor for giving a complete account of the present state of knowledge of the subject, and he has succeeded admirably in the book under review. Developing the subject in a logical order, he makes the reader thoroughly familiar with all the detailed correlations and spectra and their simpler, purely kinematical properties, before advancing to the problem of the general dynamics of decay, where one must make use of the fact that each realization of the velocity field satisfies the momentum equation of Stokes and Navier. The need for additional postulates like the 'local similarity' theory of Kolmogorov and the quasi-equilibrium theories of later authors is clearly shown, and these theories are critically explained. The probability distributions of the velocity and its derivatives are described, with physical inferences about the smallest-scale features of turbulence, and the use of the hypothesis that mean products of four velocities are related to mean products of two as for quantities obeying a joint normal distribution law, is illustrated by the calculation of the pressure correlation function. The bibliography is comprehensive, and the general layout of the book (the first of a new Cambridge series) makes for easy and pleasant reading. The dedication is "To G. I."

If, less than two years after the book was completed, the subject has moved on, this is due almost entirely to further work in the Cavendish Laboratory by Dr. Batchelor, Dr. Townsend and their associates. If the book were being re-edited, much less would be said about the general tendency to isotropy of homogeneous turbulence, which seems to be unsubstantiated for the eddies containing most of the turbulent energy. The theory that the joint distribution of velocities becomes normal in the final period of decay, so that different spectral components of the velocity are statistically independent, seems untenable because the different components each decay exponentially in that period, conserving whatever statistical dependence they may already have. Again, the theory of the 'permanence of big eddies' is currently being questioned. Dr. I. Proudman has calculated the sound field which isotropic turbulence generates.

All the time, in fact, the extent of our pitifully small understanding of turbulent motion is increasing. If all students of the subject make themselves thoroughly familiar with the material of Dr. Batchelor's book, so that they obtain a clear idea of the established knowledge without being encouraged to gloss over any real difficulties or unsimplifiable intricacies, then one may expect future progress to become faster still.

M. J. LIGHTHILL

Electrodynamics

(Lectures on Theoretical Physics, Vol. 3.) By Arnold Sommerfeld. Translated by Edward G. Ramberg. Pp. xiii+371. (New York: Academic Press, Inc., 1952.) 6.80 dollars.

FOUR of the six volumes in the German edition of Prof. A. Sommerfeld's "Lectures on Theoretical Physics" have been reviewed by Prof. R. E. Peierls (*Nature*, 168, 887 (1951); also 170, 684 (1952)), who regarded them as representing "an almost perfect choice of topics for a basic course on theoretical physics" and eagerly awaited an English translation of the series. The translation by E. G. Ramberg of Vol. 3, "Electrodynamics", fully justifies Prof. Peierls's enthusiastic comments.

This book is divided into four main parts. Maxwell's equations in vectorial integral form are the starting-point of the theory in Part 1, and the electromagnetic phenomena are derived from them systematically by deduction in Part 2, which constitutes the main portion of the volume. Special relativity and the Lorentz theory of the electron are covered fully in Part 3, and the electrodynamics of moving media is developed in Part 4. The book concludes with a selection of problems, together with answers and very helpful comments. The subject is presented in such a manner as to stimulate thought, many of the topics being originally developed by Sommerfeld and his school at Munich. The parallel nature of the magnetic induction B and the electric intensity E is stressed; they are classified as "entities of intensity", whereas the electric displacement D and the magnetic intensity H are "entities of quantity".

It is unfortunate that the book is unsuitable for use as a text-book in a third-year honours course in physics, since several topics usually associated with the subject are found in the other volumes of the series, to which many references are made. The book will, however, form a very useful reference book for advanced students.

Journey Into Wonder

By N. J. Berrill. Pp. 320. (London: Victor Gollancz, Ltd., 1953.) 13s. 6d. net.

"THE power of thought is not knowledge alone, it is the thrust of intellect as it selects this and that feature from the chaotic accumulation and builds them swiftly into a coherent pattern." So writes Prof. N. J. Berrill when viewing the limitations as a chronicler of the seventeenth-century adventurer and explorer, William Dampier. The ability to select and build from a vast accumulation of knowledge is clearly possessed by Prof. Berrill himself to a marked degree. From the accounts of the voyages of Columbus, the medieval mystic searching for the Indies and the Garden of Eden, to the harassing journeys in the Antarctic of Shackleton and Scott, he has constructed a most coherent and absorbing account of the natural history of the world's great voyages of exploration. Not only are the discoveries of the naturalist explorers such as Darwin and Humboldt, or the Forsters who accompanied Captain Cook, included, but also many interesting though unexpected observations by the buccaneers, Drake and John and Richard Hawkins.

This book, however, is much more than a judicious selection of other men's writings. It is a synthesis, containing many intriguing speculations based on the observations made by these explorers. Prof. Berrill

throws new light, for example, on the probable location of Columbus's first landing after crossing the Atlantic, gives a masterly summary of the evidence for the origins of the Polynesian race from the east and so dismisses the theory which inspired the remarkable Kon Tiki expedition, while one of his most interesting discussions is on the origin and evolution of penguins. Prof. Berrill writes with a light hand and a puckish humour which makes his "Journey into Wonder" quite wonderful. ALAN J. BROOK

Report of the Thirteenth International Horticultural Congress 1952; London, 8-15 September Vol. 1: Pp. xv+576+39 plates. Vol. 2: Pp. viii+577-1297+plates 40-100. (London: The Royal Horticultural Society, 1953.) 42s. the set.

THE Thirteenth International Horticultural Congress was held in London during September 8-15, 1952, and some of the principal contributions were reviewed in these columns shortly after the Congress (*Nature*, 170, 647; 1952). The full text of all the papers, which has now been published, makes a valuable symposium on modern horticultural problems, both practical and scientific.

Much space is devoted to the international code of nomenclature for cultivated plants, which is printed in full. The text of ten general lectures makes a valuable summary for those who have but limited time to follow the latest developments. For readers who require greater detail, there are sections on fruit growing, vegetable growing, ornamental plant growing, plant diseases and purity of stocks, on plant breeding, environmental control and on seeds. Tropical and sub-tropical horticulture is given a special section, while special symposia on citrus problems and on botanic gardens meet very specialized needs.

The hundred half-tone plates in the two volumes are of excellent quality, and very numerous line-diagrams enrich the text. The papers are published in English, French or German, but all have summaries in English and French. Scientific developments in horticulture are now taking place with such rapidity that it is scarcely possible for one individual to review, by normal methods, more than a part. An international congress brings an outstanding opportunity to review the whole, to digest the knowledge and bring it within the range of the teacher or grower, and to take stock of it. The volumes now published are worthy of the occasion.

JOHN GRAINGER

Roger Bacon In Life and Legend

By E. Westcott. Pp. 140. (London: Rookliff Publishing Corporation, Ltd., 1953.) 10s. 6d. net.

A SHORT life of Roger Bacon is an undoubted need; but the present work will not do much to fill it. The author has tried to give a straightforward account and has no axe to grind; but he would seem to be unqualified to attempt the far from easy task of presenting the facts of Bacon's life and assessing the value of his work. The book is a derivative one and is largely based on the ninety-year-old biography of Emile Charles, together with some material derived from other works of varying status. The recent great developments in the study of medieval science have passed the author by. This would matter less if the work were clearly presented; but in fact it is incoherent and confused, with not a few mis-spellings of Latin titles and proper names.

F. SHEERWOOD TAYLOR

JUBILEE OF THE UNIVERSITY OF LEEDS

By PROF. D. G. CHRISTOPHERSON, O.B.E.

THE University of Leeds received its Royal Charter on April 25, 1904. Before that date, as the Yorkshire College, it had since 1887 been one of the three constituent colleges of the Victoria University, the other two being Owens College, Manchester, and University College, Liverpool.

At the time, there were some doubts whether the College, which dated its original foundations only from 1874, would be able to stand on its own feet as an independent university. The Yorkshire College was the last of the three to present a petition for a Royal Charter, and the delay is a measure of the relative unwillingness of the College to cut adrift from the parent University.

In the upshot, from the beginning, these fears appear to have been largely groundless. Progress, although limited by lack of funds at least until the relative bounty of the years following the Second World War, has been steady. In 1904, there were twenty-seven professors, and approximately the same number of Departments. After the First World War, this number had grown to thirty-three. It is at present sixty-six. Student numbers have increased in about the same proportion. In 1949, the year in which the post-war bulge reached its maximum, there were 3,336 students, and it was supposed that when the demand from the ex-service men had been met, there would be a substantial recession. This has not happened, the number this year being 3,267. University building has also proceeded steadily: the immediate pre-war years saw the erection of the Brotherton Library, and the University Union, both now substantially overcrowded but still among the best of their kind in the civic universities of Britain. Since the War, the large and handsome Parkinson building has been completed, and a spacious new refectory which it is hoped will do much to relieve the strain upon the Union and to assist the social and cultural life of the University is nearing completion.

Developments on this scale bring their own problems, not all of which are financial. The founders of civic universities and colleges in recent times have usually had to choose at the outset between two alternative policies. They could select a site near the centre of their city, which would have great practical advantages from the point of view of convenience of access, and perhaps also, less tangibly, in fostering a greater feeling of interdependence and mutual understanding between the university and the city. Alternatively, the university could be put well outside the built-up area, where room for expansion could be easily acquired when needed, where in many cases the conditions of life were pleasanter, and where a sense of detachment could be more easily cultivated. True, a larger share of resources would then have to be devoted to building halls of residence for students; but many would take the view that this is in itself an additional point in favour of a policy of building outside the city. The founders of the Yorkshire College may have felt that in placing the College on the edge of what was then the continuously built-up area they were adopting the best compromise between these two policies. In practice, due to the enormous growth of the city over the past seventy years, they were

following the former. Their successors have succeeded to a striking extent in resisting the centrifugal tendency which a crowded site invariably produces. The University has been kept together, but at the price of severe congestion on the present site. Looking forward into the future, it can be discerned that after another fifty years much obsolescent housing will have vanished, the pall of industrial smoke which all too often covers the city will have been dispelled, and the University will be found to occupy the ideal situation, near enough to the centre to form a real part of civic life and society, compact enough for its essential unity to be apparent in every Department and to every student, and yet with enough free space for the various buildings to be reasonably sited without undue congestion. In the meantime, although no opportunity of pushing back the frontiers has been missed, progress towards adequate living-space has often seemed slow.

The Jubilee celebrations will no doubt be principally an expression of confidence in the future; but they will not be without a note of pride in the past. There is no space in this article to refer to many of the distinguished men who at various times have contributed to the academic life of the University. Exception can be made for three names only. In the years before the First World War, it was at Leeds that the Braggs achieved their classical researches on the X-ray spectrometer; in a long tenure of the chair of chemistry, Smithells built up a Department of Chemistry which has remained outstanding through the whole fifty years of the University's life; as vice-chancellor for the years 1911-23, Sir Michael Sadler did so much to broaden the purpose of the modern universities, and to achieve a synthesis of the traditions of the ancient universities and the dynamism of the new, that he can be said to have exercised a decisive influence on the history of university education in Great Britain.

Leeds has always been strong in the field of applied science. The Yorkshire College had Departments of Agriculture, Engineering, Textile Industries, Colour Chemistry, Leather Industries and Mining. The Department of Coal Gas and Fuel Industries was added in 1908, and now includes Chemical Engineering and Metallurgy. The link between these Departments and the Departments of Pure Science is very strong. Almost all technological students spend a large part of their time in the first two years of their course in the appropriate Science or Mathematics Departments, and all courses are controlled by a joint Board of the Faculties of Science and Technology. In this field, to which so much public attention has been given in recent years, the University of Leeds feels that it has an especial, perhaps a unique, experience.

The long history of technology at Leeds, however, carries with it one drawback—that all the technological departments, with the exception of the Department of Mining, are now housed in relatively old quarters, several of them in the original buildings of the Yorkshire College. As a first step in overcoming this difficulty, the Department of Textile Industries, with very substantial financial support from the industry, is going ahead with the erection of a rayon technology building. The next major item in the

development programme envisages the beginning of a new block to the north of the present site, which will provide new quarters first for the Coal Gas and Fuel Industries Department and afterwards for the engineering departments.

Fifty years is a short time in the life of a university. Compared with the slow evolution which went on through the preceding centuries, the changes which have taken place in the twentieth century are extraordinary. (But it must be borne in mind that much larger institutions have been evolved in the same time in the United States.) The question naturally arises as to whether the foundation of a university is simply a matter of material resources—money must be spent, and buildings erected, and a university will be found to have been created—or whether there is something vegetable about its growth. Many able and intelligent men—or perhaps many generations of able and intelligent men—must give their life's work before the accumulation of inherited wisdom and experience implied in the title of university can be built up. What is unseen, in academic standards, in understanding of the needs of undergraduates, in the immensely important but unpublicized field of relations between schools and universities, is more important than what can be seen and counted in buildings and departments. It may be that Leeds, in common with other relatively recent foundations, has still to complete its education in these subjects. But in fifty sessions, awareness of these intangible factors has grown continuously, and the University looks forward to its next half-century with a confidence based not only on the substantial material resources which have been built up, but also on an ever clearer conception of the purpose of a university and its place in contemporary society.

CRYSTALLINE CYTOCHROME *b*, AND LACTIC DEHYDROGENASE OF YEAST

By C. A. APPLEBY and Dr. R. K. MORTON

Department of Biochemistry, University of Melbourne,
Australia

FOLLOWING the re-discovery of cytochromes by Keilin¹, a number of different members of this important group of intra-cellular haem-proteins has been described on the basis of their absorption spectra. Particular interest is attached to cytochromes of the *b* group, that is, cytochromes *b*, *b*₁, *b*₂ and *b*₅, some of which appear to be intimately associated with certain enzyme systems. Thus, cytochrome *b* appears to be closely linked to the succinic dehydrogenase system of animal tissues, plants and certain bacteria, and it has been claimed that this cytochrome is identical with succinic dehydrogenase in *Corynebacterium diphtheriae*². Dixon and co-workers³⁻⁵, in classical studies of the lactic dehydrogenase system of yeast, found that a haem-protein which they called cytochrome *b*₂ was an essential component of this enzyme system. Although considerable purification was achieved, marked instability of the most active preparations prevented conclusive demonstration as to whether the cytochrome was the dehydrogenase (that is, the enzyme which reacts directly with the substrate) or an

essential intermediate carrier acting between lactate and the electron acceptor (methylene blue in these studies). Yeast lactic dehydrogenase is one of a small but important group of 'cytochrome *b*-linked' dehydrogenases. Since the relationship between cytochrome *b*₂ and lactic dehydrogenase has considerable bearing on views as to the nature of the enzymes of this group, we have re-examined this enzyme system of baker's yeast.

Lactic dehydrogenase activity has been determined spectrophotometrically when using potassium ferricyanide or cytochrome *c* as electron acceptors. When measuring the rate of reduction of methylene blue, we have used the Thunberg tube method⁶. Extensive preliminary studies confirmed the observations of Dixon and associates³ that cytochrome *b*₂ accompanied the lactic dehydrogenase activity throughout many different purification procedures. Moreover, the cytochrome *b*₂ was rapidly and completely reduced by the addition of lactate to active enzyme preparations. In preparations which had lost most of their dehydrogenase activity following storage, the cytochrome component was still completely, although slowly, reduced by lactate. The cytochrome *b*₂ of inactive enzyme preparations was no longer reducible by lactate, although completely reduced by dithionite. Thus, it seemed likely that the cytochrome *b*₂ was not involved in the direct reaction with lactate. Attention was therefore given to methods for complete purification of the enzyme system.

By treatment of the yeast with *n*-butanol, essentially by the method previously described by the senior author⁷, the enzyme was dissociated from accompanying lipid material which is probably of mitochondrial origin. Subsequent purification procedures, which will be described in detail elsewhere, yielded clear extracts containing the dehydrogenase activity as well as cytochromes *b*₂ and *c*. From such extracts the enzyme was eventually separated as well-formed crystals. The first crystals obtained are shown in Fig. 1. These were allowed to develop slowly and are therefore relatively much larger than those which were grown rapidly from recrystallized material and which are also illustrated. The crystals show only weak anisotropy. They are readily soluble in suitable dilute buffers at neutral pH values.

Enzymic Properties of Crystalline Lactic Dehydrogenase

The best crystalline preparations have an activity of approximately 7,000 units (μmoles ferricyanide reduced/hr./mgm. dry weight) at 20° C. and at optimal pH (8.0). With methylene blue at pH 5.2, using a reduction time of approximately 10 sec., the same preparations have activities of 740 units (μmoles methylene blue reduced/hr./mgm. dry weight) at 20° and 2,100 units at 38° C. The corresponding *Q_{MB}* values (as defined by Bach *et al.*⁸) are 16,500 and 47,000 at 20° and 38° C., respectively, and hence the crystalline enzyme is about fifteen times as active as the best preparations (*Q_{MB}* 3,000 at 38°) obtained by the earlier workers⁴.

Bach *et al.*⁸ observed that crude extracts containing the enzyme rapidly reduced cytochrome *c*, and determined the rate of reduction of cytochrome *c* manometrically in the presence of excess cytochrome oxidase. During the course of purification of the enzyme, they found that the rate of reduction of cytochrome *c* became considerably less than that of

Fig. 1. Crystalline cytochrome b_1 from baker's yeast. The initial crystals are shown in the upper photograph (a) and twice recrystallized material in the lower (b). Both photographs taken using phase-contrast. $\times 260$

methylene blue. Nevertheless, spectroscopic observation showed that their purest preparations could still reduce cytochrome c .

By direct (spectrophotometric) measurement of the rate of cytochrome c reduction during the course of purification, we have found that the rate of reduction of cytochrome c is undiminished as compared with reduction of both ferricyanide and methylene blue. The same proportionality with the three different electron acceptors is found in enzyme which has been twice recrystallized. The best preparations have an activity of approximately 1,800 units (μ moles cytochrome c reduced/hr./mgm. dry weight) at 20°C . and at pH 7.0. The reduction of a molecule of cytochrome c or of ferricyanide involves only a single electron transfer, whereas reduction of a molecule of methylene blue involves two electrons. Hence it is seen that, at 20°C ., the rates of reduction of cytochrome c (1,800 units) and of methylene blue (740 units) are of similar order of magnitude but about four to five times less than that of ferricyanide (7,000 units).

The reduction of cytochrome c by the crystalline enzyme was not inhibited by 'Antimycin A' ($1.5 \times 10^{-4} M$), which specifically inhibits the reduction of cytochrome c by the succinic dehydrogenase system of animal tissue homogenates⁷. However, a partially purified preparation of the lactic dehydrogenase was 90 per cent inhibited by *p*-chloromercuribenzoate ($10^{-3} M$) when tested with ferricyanide as electron acceptor. This suggests that certain —SH groups

are necessary for enzymic activity, as in the case of succinic dehydrogenase⁸.

Physical Properties of Crystalline Lactic Dehydrogenase

Crystals of the enzyme are distinctly pink in colour, while concentrated solutions are brown-coloured when oxidized and coral-pink when reduced with either lactate or dithionite. The oxidized enzyme shows little or no absorption in the visible region of the spectrum, but the reduced enzyme shows strong absorption bands at 556.5 $m\mu$ (α -band) and 525 $m\mu$ (β -band) as determined using a Hartridge reversion spectroscope. These bands correspond with those previously described for cytochrome b_1 by Dixon and co-workers⁴. Both absorption bands were intensified by freezing in liquid air as described by Keilin and Hartree⁹, and the α -band was shifted to 555.2 $m\mu$, while there was no observable change in the position of the β -band. The crystalline enzyme appears to be completely free from cytochrome c .

The absorption spectrum of the crystalline enzyme as determined in the Beckman spectrophotometer is shown in Fig. 2. The oxidized enzyme (curve A) shows a parahematin-type spectrum, with general absorption in the region of 550 $m\mu$ and with bands at 418 $m\mu$ (Soret) and 359 $m\mu$. There is a pronounced absorption band in the ultra-violet region, with peaks at 263 $m\mu$ and 257 $m\mu$. Curve B shows the spectrum of the enzyme reduced with lactate. The positions of the absorption bands are as follows: α , 557 $m\mu$; β , 528 $m\mu$; γ (or Soret), 424 $m\mu$; δ , 330 $m\mu$. The absorption in the ultra-violet region is similar to that of the oxidized enzyme. These curves may be compared directly with those of cytochrome c as obtained by Margoliash (see Keilin and Slater¹) and of cytochrome f (Davenport and Hill¹⁰), both of which have been highly purified but neither of which has so far been obtained in a crystalline form. It is clear, therefore, that lactic dehydrogenase activity and cytochrome b_1 are intimately associated in the crystals. Moreover, in confirmation of the observations of Dixon and co-workers⁴, there is a direct relationship between the concentration of cytochrome b_1 and lactic dehydrogenase activity as determined in several different crystalline preparations and after recrystallization.

Prosthetic Groups of Lactic Dehydrogenase

The absorption spectrum of the pyridine haemochromogen of the crystalline enzyme was determined in the Beckman spectrophotometer and found to be identical with that of the pyridine haemochromogen from a pure sample of hemin. This confirms the finding of Dixon and associates⁴ that protohem is the haem group of cytochrome b_1 , and protohem must also now be considered as a prosthetic group of lactic dehydrogenase.

A sample of enzyme which had been twice recrystallized was denatured by heating to 100° for 2 min. at pH 6.8. An equal weight of ammonium sulphate was added, and the brown protein precipitate was removed by high-speed centrifuging. The clear supernatant was a pure green colour and showed a strong fluorescence typical of riboflavin. The flavin was extracted into phenol, transferred to water, and then compared with authentic samples of flavin adenine dinucleotide, riboflavin-5'-phosphate (flavin mononucleotide) and riboflavin, using paper

Fig. 2. Absorption spectrum of crystalline cytochrome b . Curve A, oxidized; curve B, reduced with lactate; curve C, supernatant obtained by heat denaturation of enzyme. Curves are given at cytochrome concentration equivalent to 10^{-4} M-haemin. α , β , γ and δ denote absorption bands of the reduced cytochrome

chromatography. In two different solvent systems (*n*-butanol-acetic acid-water, and pyridine-*n*-propanol-water)¹¹, the unknown flavin moved as flavin mononucleotide. There was no flavin adenine dinucleotide in the enzyme extract. It is therefore tentatively concluded that the flavin is flavin mononucleotide.

The absorption spectrum of the flavin obtained by heat-denaturation of the enzyme, at the same concentration as for curves A and B, is shown in Fig. 2 as curve C. The spectrum is identical with that of flavin mononucleotide except for somewhat increased absorption in the ultra-violet region, probably due to some protein denaturation products. The contribution of this flavin to the absorption of the enzyme in the region 300–600 mμ is apparently small, since the oxidized enzyme (curve A) shows no clear indication of absorption in this region which could be attributed unequivocally to the presence of the flavin. It is possible that the decreased absorption of the reduced enzyme at 445 and 373 mμ (the absorption maxima of flavin mononucleotide) may be partly due to the reduction of the flavin by lactate, but the difference spectrum (oxidized minus reduced enzyme) is not the spectrum of flavin mononucleotide. The most noticeable contribution of the flavin (which, like the mononucleotide, has a peak at 286 mμ) to the absorption of the enzyme is undoubtedly in the ultra-violet region. The apparently small influence of the flavin on the spectrum of the oxidized enzyme

in the region 300–600 mμ may possibly be produced by modification of the flavin absorption due to combination with the protein.

The flavin group is completely bound to the enzyme, and normally none is dissociated, since freshly prepared solutions of the crystals show no flavin fluorescence. However, this always develops on storage at 0° and is increased by dialysis. The appearance of fluorescence due to free flavin is associated with decline of enzymic activity, and there is a relationship between the amount of fluorescence, as judged by visual examination, and the extent of decline in activity. It is therefore apparent that the flavin is directly concerned in the activity of the enzyme, and hence flavin mononucleotide must be regarded as a prosthetic group.

Nature of Lactic Dehydrogenase

Electrophoretic examination of twice-crystallized material has been carried out in a Tiselius-type apparatus, using 1 per cent protein in phosphate-lactate buffer, pH 7.05, ionic strength 0.25. One component, in very small amount, moved rapidly away from the main material. This was afterwards identified as free flavin, which had apparently dissociated during dialysis (40 hr.), but had not attained equilibrium with the buffer system. The protein component, however, appeared as a single peak, which remained symmetrical for more than three hours, although some asymmetry developed after five hours. This preliminary result, therefore, strongly supports other evidence that the crystalline enzyme consists of a single protein.

While further studies of the physical and chemical properties of the crystalline material are in progress, the evidence so far available strongly indicates that yeast lactic dehydrogenase is a single protein with two different prosthetic groups. Despite many attempts, we have not so far been able to isolate a separate, active flavoprotein from cytochrome b . The possibility that the flavin group is associated with an adsorbed contaminant is further excluded by the fact that, while cytochrome c and other inactive material remain in the supernatant at the initial crystallization step, the flavin as well as the cytochrome b , is almost wholly removed from the mother liquor with the crystals. The constant proportion of one haem group to one flavin group, as found in the initial crystalline product and after two further recrystallizations, also indicates that both groups are associated with the one protein. Moreover, the total purification, as compared with the initial yeast on a dry-weight basis, is at least 7,000-fold, while a tenfold purification is achieved in the crystallization step. Despite this considerable evidence in favour of homogeneity of the enzyme system, we are continuing efforts to resolve it into more than one active protein.

In the case of a single protein with two prosthetic groups, it becomes somewhat artificial to distinguish between the 'dehydrogenase' and the 'electron-carrier'. However, the two groups presumably are concerned with different functions, and we incline to the view that the flavin mononucleotide group, rather than the protohaemin, acts as the direct acceptor of electrons from lactate. Dissociation of the flavin mononucleotide group appears to be irreversible, and partial dissociation or interference with this group would account for decline or loss of

ability to reduce the protohaemin by lactate, whereas it would still be reducible by dithionite. 'Dehydrogenase' activity thus appears to be dependent on the flavin group, and 'electron-transfer' on the protohaem group. It is noteworthy that the cytochrome *b*₅ of inactive, oxidized enzyme is completely reduced by the addition of lactate together with a small amount of active lactic dehydrogenase.

Yeast lactic dehydrogenase is the first of the 'cytochrome c-linked' dehydrogenases to be highly purified. It is of especial interest in that it is itself a cytochrome, being the first of the *b* group to be considerably purified and the first cytochrome to be obtained in crystalline form. It appears to belong to a new class of enzymes not hitherto described, and may well be unique. However, evidence recently obtained with partially purified heart-muscle succinic dehydrogenase⁴ also indicates that this enzyme is dependent for activity upon a flavin group, and in this respect resembles yeast lactic dehydrogenase. It would seem quite possible that the other known 'cytochrome c-linked' dehydrogenases, namely, mitochondrial α -glycerophosphate dehydrogenase of skeletal muscle, liver choline dehydrogenase, and the malic dehydrogenase systems of certain yeasts and bacteria, are similar flavoproteins.

We wish to thank Mr. Barrett, of H. Hudson and Co. Pty., Ltd., for his helpful co-operation and for the generous gift of yeast for this investigation. We are grateful to Mr. J. Pye, of the Walter and Eliza Hall Institute for Medical Research, for carrying out the electrophoretic examination of the enzyme for us. Dr. M. Dixon suggested this problem to the senior author (R. K. M.), who commenced the investigation at the School of Biochemistry, University of Cambridge, and has continued it at the University of Melbourne. One of us (C. A. A.) is seconded from the Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization, Canberra.

existing procedures. It has, however, been clear for some time that many unusual considerations must be taken into account in assessing the potentialities of the method and that the necessary experimental evidence is only partially available, if at all. Although many features are therefore in doubt, sufficient factual information has recently been felt to be available in Britain to provide the basis for a short symposium, and such a meeting was held in Cambridge on February 10 by the Food and Microbiology Groups of the Society of Chemical Industry.

Dr. W. Wild opened the symposium with a discussion of the general properties of ionizing radiations and possible methods of producing them. Suitable sources fall into two groups: electrical generators delivering high-speed electrons or, less probably, X-rays; and radioactive sources giving electrons (β -rays) or electromagnetic radiation (γ -rays). Generators would be the more feasible source for large-scale work during the next decade, and several types might be considered, including Van de Graaff, resonant transformer and impulse generators, and travelling-wave linear accelerators. A typical generator now available has an accelerating voltage of three million volts and delivers four kilowatts of electron beam-power. This could sterilize samples, of unit density, about an inch thick (irradiating from both sides) at a rate of about a thousand lb. an hour; the cost is estimated at a few pence per lb. of treated product. Thicker samples can be treated by using higher voltage; but this must not exceed approximately ten million volts (sample thickness of about three inches) if induced radioactivity in the food is to be avoided. The British-designed linear accelerator seems to offer most promise of reliable working and also of obtaining high voltages without undue increase in capital cost; models giving several kilowatts of beam power seem feasible, although present models have only a relatively low power-output (500–800 W. at 4 million volts).

The limited penetration of electrons is an obvious disadvantage for many applications, and the much more penetrating γ -rays would often be preferred even though thick shielding would be needed to protect factory personnel from the radiation. Two main sources can be considered: the spent reactor fuel rods in their initial 'cooling' period; and the residues (fission products) which remain after chemical processing of the fuel rods. A medium-sized nuclear power station could probably deliver a million rads to a thousand tons of food a day from the former source; little special provision would be needed except a device for presenting the food to the radiation, provided that the food could be brought to, or near to, the power station. Fission products, on the other hand, could be processed into transportable sources for use in more distant factories, assuming that methods could be developed for moving, safely, the megacurie sources required. It is still too early to estimate, reliably, the probable cost of fission-product radiation, although costs comparable with those for existing electron generators seem possible. The technique of preparing sources has yet to be developed, however, and the potential demand is unknown. It would therefore be preferable at this stage to adopt the alternative approach, as in the United States, of asking industry to indicate what would be regarded as acceptable processing costs. Dr. Wild concluded by saying that further details are available in several publications and that either

PRESERVATION OF FOODS WITH IONIZING RADIATIONS

POWERFUL sources of ionizing radiations have become increasingly available during the past ten years, and a corresponding interest has developed in their use for industrial purposes. Among the possibilities which have received some attention is the utilization of the lethal effects of these radiations for killing micro-organisms in food, thus reducing or eliminating the primary cause of most types of spoilage. If this could be effected without materially damaging the food, and at economical cost, the process could represent a marked advance over

he or his colleagues at Harwell would be glad to discuss them with anyone interested.

Dr. L. H. Gray then outlined present views of the biological effects of irradiation. The primary process is a physical act of energy absorption which leads to the excitation and ionization of individual atoms. The biological damage which results, however, takes several forms, among the most important of which is a loss of the property of cell reproduction; this is eventually followed by cell death or in some circumstances by differentiation. Other less-damaged cells show a partial recovery from the effects of irradiation; but these are generally overgrown by normal or only slightly injured cells. A small proportion of the cells which survive will also usually be found to have undergone a mutation. Tissue cells show a type of response which should particularly be noted, for they give rise to tumours. This carcinogenic effect of irradiation, which is little understood, deserves very serious consideration in connexion with the sterilization of foodstuffs. In studying the cause of these effects it has been found that direct tests of metabolic activity such as respiration, glycolysis and adenosine triphosphate synthesis show little change even with quite high doses. Many important enzyme systems are therefore not damaged; but metabolic steps are undoubtedly involved in the development of radiobiological damage.

The probability of any small unit of biological organization being directly ionized is quite small until the dose reaches levels of the order of millions of r.e.p.; but there is a much greater probability of attack by free radicals arising in the aqueous phase. Various factors such as radiation quality and oxygen tension can be shown to affect indirect chemical reactions of this type in a manner which strikingly parallels their effect on biological response, and it is now believed that much radiobiological damage is due to the action of free radicals arising immediately from water or of more stable radicals to which they give rise.

The last two papers of the symposium were concerned more with the practical aspects of the effects of irradiation on typical food systems. A paper on the effects on micro-organisms by Drs. R. S. Hannan, Marguerite I. Davis and M. Ingram was read in two parts by the first two authors. Dr. Davis first described the general features of the response of micro-organisms. The most important effect is that, with sufficiently large doses of irradiation, the organisms fail to multiply, and this can be accounted for broadly in terms of an ionization having occurred in a sensitive region of the cell. It has recently become apparent, however, that the lethal effect of a given dose can be modified by changes in the environment of the organism, such as removal of oxygen, addition of several types of protective compound, removal of water or change of temperature. These effects are of great practical importance, since they indicate that the dose required to inactivate micro-organisms in a food product will depend to some extent on the nature of that food and the method of processing.

Dr. Hannan then showed how the lethal effects might be utilized. Several workers have shown that even the most resistant spores, in broth suspension, can be inactivated by doses of the order of 2×10^6 r.e.p., that is, equivalent to a temperature rise of 4 deg. C. Yeasts, moulds and vegetative bacteria are somewhat more sensitive. Sterilization without heating is therefore possible and is the most interest-

ing potential application. Much work is still needed with practical food systems; but it seems possible that doses up to 3×10^6 r.e.p. may eventually be found to be necessary, partly to allow for individual circumstances which might protect the micro-organisms and partly to ensure, with a high degree of certainty, that all samples in a given batch will be sterile. Much lower dose-levels might find practical use, however. Approximately 5×10^5 r.e.p., for example, inactivates many of the micro-organisms in most foods and delays the onset of microbial spoilage; harmful vegetative organisms are also destroyed. Even lower doses of $2-5 \times 10^4$ r.e.p. have been used to break the reproduction cycle of insects in foods (for example, *Trichina* larvae or wheat weevil). Very large doses, however, probably of the order of $1-5 \times 10^6$ r.e.p., are needed to inactivate viruses.

Dr. Hannan then went on to describe the effects of irradiation on the foods themselves. The greatest obstacle to the application of the process, apart from economic considerations, is the fact that chemical damage to the food itself can seldom be ignored. Prohibitive changes in colour, odour and flavour frequently occur, and the study of these effects is still largely in the empirical stage. It is clear, however, that the chemical change is limited in total extent (of the order of a few μ moles/gm. for a sterilizing dose) and is of two main types: the indirect effects in the aqueous phase, described by Dr. Gray, and a complex series of effects in the lipids. The most obvious changes appear to be oxidative. Freezing before irradiation, removal of oxygen and adding 'protective' compounds materially decrease many of these effects, and the suppression of damage with most products at high dose-levels usually depends on the feasibility of using auxiliary processes of this type.

Raw beef irradiated with a sterilizing dose of 2×10^6 r.e.p., for example, develops a strong, unpleasant, irradiation odour and flavour; but these can virtually be eliminated by de-aeration and deep-freezing before irradiation. This would be difficult to apply on an industrial scale, however, and an alternative procedure of adding protective compounds, including ascorbic acid, which dispenses with the freezing operation, would be commercially more attractive. Unfortunately, however, this only partially controls the radiation damage, and the chemical basis of the protective action is, moreover, far from clear. In a brief survey of the irradiation of a range of foods, Dr. Hannan pointed out that most products of animal origin develop typical 'irradiation' odours and flavours, and require similar protective techniques. This is especially true with dairy products, where the flavours are usually very strong. Many processed and cured meats show relatively little flavour change, however, presumably owing to the protective effect of nitrite and fat antioxidants which are usually present. The treatment of fruits and vegetables raises many difficulties, if only from the action, during storage, of enzymes which are not usually inactivated by irradiation. The storage life of many other types of product is, in fact, limited by chemical and enzymic change during storage. Even at dose-levels of the order of 5×10^5 r.e.p. which might be used for retarding microbial spoilage, 'irradiation' flavours are usually marked, and it is not until 10^6 r.e.p. or even less that the threshold of sensory detectability is reached with many products. Little change would usually be detectable with doses of the order of 2×10^4 r.e.p.

which might be used for disinfection; but even at this dose-level it is necessary to consider carefully how far irradiated foods can be considered suitable for human consumption. Desirable constituents such as vitamins might be partially destroyed; but the greater possible danger is that harmful compounds might be formed. There has been no positive demonstration that this is a significant danger; but a very great deal of evidence would be required before it could be discounted.

An active discussion followed, most of which was concerned with matters of detail; but one point is noteworthy: the view was expressed that the basis for assessing the potential toxicity of irradiated food need not necessarily be more rigorous than that applied to other methods of processing. It would be illogical to demand the complete characterization of every chemical change irradiation might produce, since this is not even known for kitchen cooking.

No positive conclusion can be drawn from the proceedings of this symposium except that the process is highly novel and of obvious interest. There is, however, no firm indication that it would be commercially applicable in Britain in the near future in any of its many forms. Even if the effects of radiation on foods and micro-organisms were to be clarified, there would still be many problems in assessing the economic value of the process and translating the laboratory results to the factory. The present position is therefore still one of seeking products and methods of processing which offer such unmistakable advantage that the developmental problems can be attacked and overcome. Suitable products may well be found more easily in the pharmaceutical than in the food industry.

R. S. HANNAN

OBITUARIES

Sir Nelson Johnson, K.C.B.

NELSON KING JOHNSON was born on March 11, 1892. He was educated at Canterbury, his native city, and at the Royal College of Science, London, of which he was an associate. After taking his degree he worked for a time on astrophysics under Prof. A. Fowler. In 1913 he went to the observatory at Sidmouth founded by Sir Norman Lockyer for research in solar physics. When war came in 1914 he joined the Royal Flying Corps and became one of the early night-flying pilots. On a night of bad visibility he had a serious crash and this, combined no doubt with the influence of W. J. S. Lockyer, meteorologist as well as solar physicist, led Johnson to the Meteorological Office at the end of the First World War. In 1921 he was put in charge of the new meteorological section of the Chemical Defence Research Establishment, from which so much of our knowledge of the lower layers of the atmosphere has since come.

Johnson himself carried out two investigations of the temperature at different levels by continuous records day and night, for three years at Porton and for five years at Leefield, where he had the assistance of G. S. P. Haywood. No such comprehensive investigation of this problem had previously been undertaken; and no one familiar with the difficulty of eliminating the many sources of error in the continuous measurement, in all conditions of weather, of

atmospheric temperature at levels up to 300 ft., can but admire the way Johnson surmounted the difficulty. A very full analysis and discussion of the records was published in the *Geophysical Memoirs* of the Meteorological Office. Mention may be made of two unexpected results. The rate of increase of temperature upwards at the end of clear calm nights falls off much more rapidly with increasing height than had been expected on the plausible assumption that radiation was the main operating factor; and, most surprisingly, the mean temperature over the twenty-four hours of the day, generally supposed to decrease upwards, was found to increase upwards on the average of the whole year, to a height of 100 ft. Recent records from the tower at Rye, erected at Johnson's instigation, to investigate the vertical distribution of humidity, the fundamental factor in the strange, but vitally important, anomalous radar phenomena, show that there the increase of temperature persists up to 300 ft.

After 1928 Johnson became successively director of experiments at the Chemical Defence Research Establishment at Porton and chief superintendent of the Chemical Defence Research Department of the War Office. During this period the defence arrangements against gas attacks, including the gas masks, admittedly superior to any others in the world at that time, were brought to such a pitch of perfection that they were a major factor in deterring the Nazis from attempting gas attacks against Britain or against her ally, the U.S.S.R., whose civil population had no such effective protection.

In September 1938 Johnson returned to the Meteorological Office as director. His happy combination of scientific comprehension and administrative ability won the admiration of his staff. He devoted all his energy and his time to the task of meeting the demands which the threat of imminent war and, a year later, the outbreak of war, made upon the Office. His foresight enabled him to meet the unprecedented requirements for staff and equipment for Army and Air Force needs not only in the United Kingdom and in the expeditionary forces in Europe and North Africa, but also in the Middle and Far East, in the Colonies, Malta, Iceland, the Azores and partially in Canada and South Africa.

But Johnson was not only an able administrator; he never lost sight of the need for fundamental research. He instituted the Meteorological Research Committee with Prof. S. Chapman as its first chairman; he secured the establishment of the Meteorological Research Flight, the contributions of which to our knowledge of the upper atmosphere, especially of humidity in the stratosphere, have been outstanding; and he formed a section for research in forecasting, working in contact with, but freed from the routine duties of, the operational forecast service.

Meteorology is more dependent than any other science on international co-operation. Johnson took the lead after the Second World War in convening an international meeting in London at the beginning of 1946. He was elected chairman of the International Meteorological Committee and in 1947 president of a general 'Conference of Directors' at Washington, where he achieved an outstanding success. He secured agreement among these directors and their diplomatic advisers, including those of the U.S.S.R. and countries in the Soviet block, on a Convention of Governments establishing an official World Meteorological Organization with the necessary

financial provision and an agreed degree of flexibility in its operation. When the Conference was on the point of breaking down, it was, to quote the words of the Chief of the U.S. Weather Bureau, "the deliberate and skilful guidance of the President" which brought them through all obstacles.

Johnson was made K.C.B. in 1943. We who served under him appreciated and admired his ability, and I am assured that those who served with him and under him in chemical defence research share our feelings and mourn our loss. The strain of the past fifteen years caused or accelerated the development of Parkinson's disease, which defeated our hopes that he would regain his health after his retirement at the end of August last; he died on March 23.

Throughout nine years I saw almost daily evidence of his quiet power and his thoughtful tact. I may mention one illustration. A member of the staff had got into difficulties through his own blunder and deserved censure. When the matter came to Johnson, his first words to me were, "How can we help X out of his difficulties?" He was not only kind; he was strong. When he had decided what was the right course, he could state clearly the decisive reasons for it and reveal reserves of power behind an unassuming manner. The Chief of the U.S. Weather Bureau said the Washington Conference owed him a debt of gratitude; so does his own country.

E. GOLD

Prof. K. Honda

His death occurred on February 12 of Prof. Kotaro Honda in his eighty-fourth year, an almost legendary figure in the field of physical metallurgy and applied physics. Born on February 23, 1870, the second son of Hyozaburo Honda, in the Aichi Prefecture of Honshu, Japan, he graduated in 1897 as a physicist from Tokyo Imperial University. Making his mark while still a research student, he published several papers in collaboration with Prof. H. Nagaoka and alone, on the dimensional effects of magnetization on iron and steel, nickel and cobalt. In 1901 his University appointed him a lecturer in physics and in 1903 conferred the D.Sc. degree on him. During this period his researches were devoted mainly to magnetic subjects such as the dimensional effects observed at high and low temperatures, the effect of stress on magnetization, and the change in the elastic constants of ferromagnetics with magnetization. His wide interests at this time are demonstrated by several papers on geophysical matters. Honda repeated and extended a great deal of the magnetic work done by earlier investigators but exercised greater care and added many refinements, often in very simply conceived apparatus.

Between 1907 and 1911, Honda travelled as a research fellow in Germany, France and England. While in Europe, he worked under Prof. G. Tammann, of the University of Göttingen, in the field of metallurgy and under Prof. du Bois on magnetism. In 1910, he published a famous paper covering the first extensive and systematic investigation made into the magnetic susceptibilities of the elements, about forty in all, but most of the data are now considered unreliable because of impurities. Following his period abroad, Honda was appointed professor of physics at the then newly established Tôhoku Imperial University at Sendai.

A long and prolific period of valuable experimental and theoretical work then followed, on the magnetic

properties of elements and alloys at high and low temperatures; contemporary theories of magnetism; the structure of magnet steels; the solution of equilibrium diagrams by magnetic analysis; the invention of K.S. permanent magnet steel in 1920 (now better known as 35 per cent cobalt magnet steel); the nature of the transformations in pure iron and carbon steels; the theory of the quench-hardening of steels; the study of the formation of cementite; the production of single crystals of iron, cobalt and nickel and their magnetic investigation; the study of martensite; and the development of the new K.S. permanent magnet alloy in 1934. Indeed, his stimulating contributions covered so many branches of the physics of solids and physical metallurgy that it would be invidious to single out any one group for special comment.

Honda's contribution to the establishment of fundamental and applied scientific research in Japan cannot be over-rated; and his influence on, and encouragement of, his students and research associates gave rise to the large output of valuable papers which appeared in the *Tôhoku Science Reports*. He was appointed director of the Research Institute for Iron, Steel and other Metals in 1919, after fostering its foundation. He was also elected a member of the Imperial Academy of Science; the National Research Council of Japan; the board of directors of the Foundation for the Promotion of Science and Industry in Japan; and the Tokyo Institute of Physical and Chemical Research. Finally, he became president of the Tôhoku Imperial University in 1931, which appointment he held until his recent retirement.

A notable stage in Honda's career was reached in 1936, when he attained his twenty-fifth anniversary as professor of physics in the Tôhoku Imperial University. This was marked by the publication of the "Honda Anniversary Volume", a unique compilation including papers from past pupils and colleagues and contributions from leading physicists of international repute.

The Iron and Steel Institute conferred its highest honour, the Bessemer Medal, on him in 1922; this was only one of many awards and honours received by Prof. Kotaro Honda from Great Britain, the United States and Germany, which confirm the great international esteem in which both the man and his work were held.

Prof. Eugeniusz Romer

The death of Prof. E. Romer on January 28 at the ripe age of eighty-four marks the end of an era of cartographical and geographical development in Poland for which he was so largely responsible. His forceful and dynamic personality never failed to make its mark whenever he attended a meeting or conference and will be recalled with pleasure by the many friends he made in Britain at the International Geographical Congress of 1928. The high standard of official maps of Poland and the wide range covered are due especially to his efficient direction. He remained mentally vigorous almost to the day of his death, and in his retirement had turned his attention to some theoretical aspects of geomorphology, notably the development of the river systems of Africa. It is hoped that a summary of this work in English, already planned at the time of his death, may appear posthumously.

L. DUDLEY STAMP

NEWS and VIEWS

Physics at Bangor: Prof. E. A. Owen

PROF. E. A. OWEN retires in September this year from the chair of physics in the University College of North Wales, Bangor, which he has held for the past twenty-eight years. A graduate and 1851 Exhibition Scholar of the University of Wales, Prof. Owen went to the Cavendish Laboratory, Cambridge, in 1910 for postgraduate work under J. J. Thomson, where his work on X-ray absorption led to the discovery of the λ^3 law which is associated with his name. He afterwards joined the staff of the National Physical Laboratory, Teddington, at first holding a post in the Metrology Division, and later became head of the Radiology Section of the Physics Division. There he was largely concerned with the protection of hospital staff in X-ray and radium departments and with X-ray dosage measurements. He served for many years as secretary both to the British and to the International Committee for Radiological Units and took a prominent part in establishing the roentgen as the unit of X-ray dosage and in having it adopted as the international unit. At the National Physical Laboratory, in addition to organizing the routine work, Prof. Owen was active in promoting original research. Under his guidance, with the active co-operation of the late Walter Rosenhain, then superintendent of the Metallurgy Division, and G. D. Preston, now professor of physics in University College, Dundee, work on the crystal structure of metals and alloys was started in 1922 and has continued at the Laboratory ever since. He was also interested at this time in the reflexion of electrons from crystal surfaces, and it is worth while recording that he was only narrowly forestalled in the discovery of electron diffraction. During the tenure of his chair at Bangor, Prof. Owen has built up a reputation for the application of X-ray methods to the elucidation of the structure and properties of metals and alloys. The work of his Department has been characterized by attention to detail and accuracy of X-ray measurements which have done much to throw light on many phase diagrams of binary alloys and related problems.

Dr. E. R. Andrew

DR. E. R. ANDREW, who succeeds Prof. E. A. Owen, has had a distinguished scientific career at Cambridge and Harvard, and latterly at the University of St. Andrews. An open scholar of Christ's College, Cambridge, he took first-class honours in Part 2 of the Natural Sciences Tripos in 1942, and then went to the Radar Research and Development Establishment, where he worked mainly on problems of radar reception and display. He returned to the Royal Society Mond Laboratory in Cambridge after the War to do research on superconductivity and was elected Stokes Student at Pembroke College in 1947. His research was principally concerned with the problem of the intermediate state, that is, the break-up of a superconductor into alternate regions of normal and superconductive material when a rod or plate of the superconductor is subjected to a transverse magnetic field of sufficient strength. His experimental and theoretical work cleared up much that was uncertain in the phenomenon and showed unmistakably the very important part played there by the surface energy of the boundary surface between normal and superconductive regions. Dr. Andrew left the Mond Laboratory to spend a year as

Commonwealth Fellow at Harvard University and was then appointed to a lectureship in natural philosophy in the United College of the University of St. Andrews in 1949. At Harvard he began his work with Prof. Purcell on proton magnetic resonance in solid hydrocarbons and has continued this at St. Andrews, where he has designed and had built a very large permanent magnet which has a highly uniform field, such as is needed for this kind of research. The work which he and his research students have carried out on nuclear magnetic resonance in molecular hydrocarbon crystals has yielded much valuable information. It has been possible to determine unambiguously the positions of the protons in many molecules, to determine the modes of rotation of the hydrocarbon molecules in the lattice, to measure the frequencies of rotation and the height of the potential barriers which hinder rotation and, further, to show, in such crystals as benzene, that the molecules are very free to migrate between lattice sites even at temperatures well below the melting point of the solid.

Agriculture at Nottingham: Prof. F. L. Milthorpe

DR. FREDERICK LEON MILTHORPE, head of the Department of Plant Physiology at the Waite Agricultural Research Institute, University of Adelaide, has been elected to the newly established chair of agricultural botany in the Department of Agricultural Sciences at the School of Agriculture in the University of Nottingham, as from next October. Dr. Milthorpe is an agricultural science graduate of the University of Sydney, and in 1940 became a plant pathologist in the New South Wales Department of Agriculture, a position he held until 1946. During this period his research work concerned the search for rubber substitutes, the growth of fibre flax and of vegetable crops, and diseases of deciduous fruits. During 1946-49 he held a Farrer Scholarship and a Leverhulme Research Fellowship at the Imperial College of Science and Technology, London, investigating the drought resistance of cereals. He has continued research in problems of water relations of plants while holding his present appointment, since 1950, as senior lecturer in charge of plant physiology at the Waite Institute in South Australia.

Geography at University College, Swansea:

Prof. W. G. V. Balchin

DR. W. G. V. BALCHIN, who has been appointed to the newly established chair of geography at University College, Swansea, received his early training in the Cambridge School of Geography. After serving as demonstrator at Cambridge, he worked in the Hydrographic Department of the Admiralty during the War and was appointed lecturer in geography at King's College, London, in 1945. He has worked in the fields of geomorphology and climatology, making notable additions to our knowledge of coastal processes, of the erosion surfaces of south-west England and to the study of local climates. In 1952 he organized an expedition to Arizona in association with Mr. Norman Pye, of the University of Manchester, and the first fruits of the work then done are in course of publication. He had earlier visited Spitsbergen with the 1938 University of Cambridge expedition. His contributions to his subject have been recognized this year by the receipt from the Royal Geographical Society of the Gill Memorial Award. As head of the Department at Swansea he is well equipped to establish a school, giving full

attention to the physical and cartographic aspects of the subject and thus providing a valuable complement to the well-known and long-established school of human geography at Aberystwyth.

Geography at Southampton: Miss F. C. Miller

MISS F. C. MILLER, head of the Department of Geography in the University of Southampton, is retiring at the end of the present academic year. Miss Miller has been a lecturer at Southampton since 1921 and head of the Department for many years. She has maintained the status of the Southampton Department, one of the earliest in the country. The Department has contributed to the subject many academic workers now holding responsible positions in several universities in Britain.

Mr. F. J. Monkhouse

MR. F. J. MONKHOUSE, of the University of Liverpool, has been appointed to succeed Miss Miller, with the title of professor. Mr. Monkhouse graduated in 1935 with a first in the Cambridge Geographical Tripos and, after experience as geography master in several grammar schools, joined the Naval Intelligence Division of the Admiralty in 1941. He was one of the team of workers which produced the "Geographical Handbooks" for Service use; his own contributions were chiefly on West European countries. After a short spell in Ceylon with the Inter-Service Topographical Division, he was appointed to the Department of Geography in the University of Liverpool in 1946. While in Liverpool, he has been most active in both teaching and research. In particular, he has developed cartographical teaching to a high level and, in collaboration with Mr. H. R. Wilkinson, also of the Liverpool Department, has written "Maps and Diagrams", which has become a standard text. His book "The Belgian Kempenland" (in the series "Liverpool Studies in Geography") and his papers on the economic geography of the Low Countries indicate his interests in the economic geography of Western Europe, and he has in addition a number of papers on the historical geography of England, including a chapter on Worcestershire in the forthcoming second volume of Prof. Darby's "The Domesday Geography of England".

Element 100

THE announcement in *The Times* of April 12 of the production of element number 100 by Prof. G. T. Seaborg and his collaborators at the University of California follows closely on their discovery of element 99 (see *Nature*, February 13, p. 290, and *Phys. Rev.*, 93, 257 and 908; 1954). Although full details of this work have not yet been published, it is clear that extreme care in the handling of minute quantities of short-lived radioactive products was necessary, and the successful outcome of the experiments is a major technical achievement. The mass number of the isotope of element 100 that has been identified is given as 263, and its half-life is about three hours. It was prepared from a plutonium isotope (presumably plutonium-239) by successive neutron capture, which increases the mass, followed by beta-decay, which increases the atomic number. As a first stage in the process, californium (element 98) was separated chemically from the irradiated plutonium, probably by ion exchange and precipitation methods; the californium in turn was bombarded by neutrons, and elements 99 and 100 so

obtained. Since it appears that at least fourteen neutrons must have been added to the original material to arrive at the mass number quoted, it is obvious that the work demanded very intense neutron fluxes, such as are available in the reactors of the U.S. Atomic Energy Commission. Identification of the new isotope was presumably based on the α -decay systematics, built up by Prof. Seaborg and others, which have proved extremely reliable in this field. Element 100 is stated to behave chemically like erbium, its analogue in the rare-earth group. There is no reason for believing that this will be the last new element to be prepared, although the increasing probability of spontaneous fission as the atomic number advances would appear to limit the total number of elements to about 110.

Colonial Relations in the British Commonwealth

REPLYING for the Government in a debate in the House of Commons on April 2, initiated by Mr. C. J. M. Alport on a resolution calling for re-examination of the spheres of responsibility of the Colonial and Commonwealth Relations Offices and reorganization of the services for which they are responsible, the Minister of State for Colonial Affairs, Mr. H. Hopkinson, rejected the suggestions made in the debate for appointing a Secretary of State for Africa, merging the Colonial Office and Commonwealth Relations Office, or transferring the economic functions of the Colonial Office to the latter Office. In the Government's view the time has not yet come for any major definition of the spheres of responsibility between the Commonwealth Relations Office and the Colonial Office. Nevertheless, it might be desirable to examine the relations between the respective services and the need for the reorganization of the Colonial Office as a whole. In the view of the Government, re-examination of the conditions of service of members of the Colonial Service is urgently needed, for it is of the greatest importance that Colonial officers should be assured that their problems and anxieties are understood and treated seriously.

Mr. Hopkinson did not think that the proposal for a joint Commonwealth service would help this particular problem, but he would not exclude schemes in which Colonial servants, as part of some new overseas service, could be made available when required by independent Commonwealth countries or indeed by foreign countries. The Government recognizes that it has a special responsibility towards officers of the Colonial Service who, appointed to their present posts by the Secretary of State, are in those areas developing towards full self-government which are anxious to ensure that officials retained by them should owe principal allegiance and loyalty to them. Up to now, Colonial Governments have not behaved irresponsibly or unfairly towards their British Civil servants, but the Government feels that, as long as these officers remain, they should be assured of certain basic conditions of service, including pensions and other benefits, retention of their status in H.M. Colonial Service, and possibilities of transfer and promotion, and so on. At the same time, they should be permitted to retire from the service of the Colonial country by which they are employed when it attains independence. The Government, said Mr. Hopkinson, believes that there is still a great work for these officers and wishes them to know that the House and Government are aware of their needs and are determined to give them every practical assistance for carrying on their great task.

Age of Election to the Royal Society

IN a recent note, Prof. A. V. Hill has discussed the age of election to the Royal Society of London (*Not. and Rec. Roy. Soc., Lond.*, 11, No. 1; January 1954). For many years, up to and including 1930, the number of annual elections to fellowship of the Royal Society (apart from 'special' elections under Statute 12) was fifteen. During 1931-38 it was seventeen, during 1939-45 it was twenty, and since 1946 it has been twenty-five. The 'median' age of election (that is, the age above which as many elections occur as below it) has been shown as: 1848-72, 42; 1873-97, 43; 1897-1922, 44½; 1920-38, 47; 1939-45, 49½; 1946-53, 47½. These figures include elections in all scientific categories. In eight different categories the median ages have been:

	1920-38	1939-53
Mathematics	43	42
Physics	39	44
Chemistry	45	45
Engineering	55	54
Geology	53	51
Botany	51	52
Zoology	48	50
Physiology	48	49

This confirms the general conclusion that there has been little change over the past thirty-four years, though this is probably due mainly to the fact that the number of annual elections has increased in the ratio of 5:3. The median age of election differs greatly between the categories; and this difference is the more striking when it is recalled that practically no elections take place under thirty-two, so that, for example, half the elections occur in ten years in mathematics and in twenty-two years in engineering. One reason for this difference is that in some subjects experience is far more important than in others, where natural ability is the chief element in success. Prof. Hill writes that the number of scientific people qualified for election is rising rapidly and that, if seventeen elections annually were appropriate in 1931, twenty-five will be too few before long. The number of annual elections should be adjusted from time to time so that the median age of election could be kept around forty-five.

Impact of Science on Society

RECENT copies of the quarterly magazine, *Impact*, have contained articles of considerable interest to those interested in the social aspects of science. In the latest issue, Dr. A. King states that international collaboration in scientific research and development can be extremely valuable only if the projects are appropriate for international effort and present real advantages over normal national or institutional means. International scientific co-operation should be based on real needs rather than on idealistic or political principles (4, No. 4; Winter 1953). An earlier issue of the journal contains an article by Dr. C. Sarnie on the scientific detection of crime; he shows that the introduction of scientific methods in the detection of crime is of great social value because it makes for greater certainty in the administration of justice (4, No. 3; Autumn 1953). In the Summer 1953 issue (4, No. 2), R. T. Eddison has contributed a valuable article on the social application of operational research, and Dr. Armando Cortesao, the distinguished Portuguese historian of science, has shown how the application of nautical science made possible the great geographical revolution at the end of the fifteenth century. *Impact* is available at H.M.S.O., price 2s. 6d. for each issue.

Imperial College of Science and Technology, London

AN account of research activities carried out at the Royal College of Science during the three years, 1950, 1951 and 1952, has recently been published. The publication is a brief general review and is written in non-specialized terms similar to the booklet issued by the City and Guilds College last year to describe its research in engineering. Contributions are included from eight departments of the College, including botany, inorganic and physical chemistry, organic chemistry, geology, mathematics, meteorology, physics and zoology and applied entomology. The greatest range of investigation has been carried out in the Department of Inorganic and Physical Chemistry and varies from analyses of the structure of solids to the physical chemistry of ion-exchange resins as well as problems of crop nutrition and insecticide chemistry. In the Department of Geology, studies have been carried out on the Caledonian Mountains of Britain, while, in the Department of Mathematics, theoretical cosmology has been one of the fields of investigation. The report is admirably written and discreetly illustrated. It is hoped that, next year, the Royal School of Mines will publish a similar booklet, so completing a trilogy of publications of this sort for the three colleges which make up the Imperial College of Science and Technology.

Rugby School Natural History Society

THE Report of the Rugby School Natural History Society for 1953 is the eighty-seventh in the series and reveals that the Society is in a flourishing state and is keeping up a long and splendid record of work. The museum has been redecorated and extended, and the vivarium improved mainly by clearing, cleaning and restocking the pond. During the year, four lectures were given by visiting specialists. The ecology of a pond has been the subject of study for about thirteen years. An account of the period 1940-46 was published in the Report for 1946, and in the present Report the account, with illustrations, has been brought up to date. A bird census for 1953 is given. T. Fawcett describes work on an excavation at Brownover, where pieces of interesting medieval pottery were unearthed; so also were two St. Neots ware sherds dating from late Saxon time and believed to be the first found in Warwickshire. Reports of the library, museum and vivarium and of the Society's field sections—zoological and entomological, ornithological, geological, archaeological—are here published. (It is curious that the Society seems to have no botanical field section, though judging from the report of the zoological and entomological section, its members also admit botany.) Affiliated sections also report their year's activity; they comprise architectural, meteorological, photographic, astronomical, chemical and physical, railway, wireless and aero-modelling. Numerous prizes covering many aspects of science are being offered. Rugby School is to be congratulated on the excellent work being done by its Natural History Society and affiliated sections.

Science Service of the Canadian Department of Agriculture: Annual Report for 1952-53

THE annual report of the Director of Science Service of the Department of Agriculture, Canada, for the year ended March 31, 1953 (pp. 56 + 4 plates. Ottawa: Queen's Printer, 1953), which is reprinted from the report of the Minister of Agriculture,

endeavours to give a representative picture of the work going on in the Ministry's various laboratories across Canada, more particularly the work directly related to important problems in agriculture and forestry. The extent and variety of this work is shown in a list of 284 research papers published during the year, which is appended to the report. In animal science, investigations were concerned with the basic aspects of nutritional and physiological problems and the protection of livestock and man from animal pests. Experiments in Alberta with spraying and dusting machines, for example, showed that spraying sheep with DDT in the spring was effective against tick, being more rapid than dusting and easier on the animals. Loss of repellency of dimethyl phthalate to mosquitoes was found to be due largely to absorption through the skin, while a rotary-brush spraying device attached to aircraft, which has been developed by the Entomology Division, proved the most effective and economical spraying device so far tested. In plant science, emphasis is placed on researches relating to hazards confronting farmers and foresters from plant diseases and insect pests, and the bulk of the report records the many useful results obtained in such investigations. A further section of the report describes the work in soil science, including microbiology, soil chemistry, taxonomy and antibiotics, while professional services, both organized and informal, which were rendered to different groups within the Department of Agriculture, to other Dominion Departments and to the public, constitute an important feature of the activities of the Department.

Carotid Rete and Its Associated Arteries

A PAPER entitled "Studies of the Carotid Rete and its Associated Arteries", by P. M. Daniel, J. D. K. Dawes and Marjorie M. L. Frichard (*Phil. Trans. Roy. Soc., B*, 237, pp. 173-208 + pls. 12-19; July 1953; 8s.), records an investigation into the cranial arteries in a series of mammals more particularly with respect to the well-known rete mirabile cerebrale, here termed the carotid rete. The animals employed were cat, sheep, ox, goat, pig, dog, rabbit and rat. The rete was found to be well developed in the first five, in a very much reduced form in the dog, but not at all in rabbit or rat. The techniques employed were the use of radio-opaque injection masses from which stereoscopic radiographs were taken, and of injection with neoprene latex. After the setting of the latter, the vessels were dissected *in situ* or the tissues were completely macerated, leaving only the casts of the blood-vessels. This enabled the position of the main vessels in relation to one another and to the bony tissue, the relation of the vessels to the soft tissue and finally the detailed structure of the rete and its associated vessels, to be readily ascertained. How successful the neoprene latex injections were is clearly shown in the nineteen excellent photographs on the eight plates. The rete is found to be intimately associated with the major arteries supplying the brain, and its presence is associated with a reduction or absence of the internal carotid artery. This is still true of the cat where, in contradistinction to the artiodactyles, the rete is extracranial, lying in a venous lake surrounding the internal maxillary artery immediately below the base of the skull. In the other forms the rete lies intracranially in the cavernous sinus. The rete itself consists of a network of medium-sized arteries about 250 μ in diameter, which interlace and anastomose in a complicated

manner. It would appear from its size, its complexity, its relation to the cranial blood supply and its close association with venous blood, that it must serve some functional need; but what this need is or how it is served remain unsolved problems.

The Oriental Earthworm

THE value of earthworms in increasing fertility of the soil is well known. There are situations, however, in which the good done by earthworms is outweighed by the damage and inconvenience that they cause. In recent years a new species, the Oriental earthworm, *Pheretima hupoiensis*, has appeared in Connecticut and other eastern states of U.S.A. It has proved to be a much more serious pest than the native species and is more or less immune to treatments used to kill native earthworms. J. O. Schread has described the habits of the new earthworm and experiments on its control in specialized turf areas (Bull. 556; April 1952; Connecticut Agricultural Experiment Station, New Haven). The worm is apparently very prolific and the production of hundreds of casts following heavy rainfall has seriously damaged golf greens; hundreds of pounds of castings have been left on each heavily infested green every year. Control measures used for native earthworms were not effective in controlling the Oriental earthworm. Parathion applied four times, totalling about a hundred pounds per acre, reduced the population about 97 per cent; some injury was caused by the final application. Chlordane emulsions were more effective than wettable powders. Single treatments using 40 pounds of chlordane per acre had a highly killing effect and prevented reinfestation for long periods of time. Aldrin in the form of either wettable powders or emulsion at the rate of 33 pounds per acre first activated the worms, but provided good control after several weeks. Other chemical reagents also produced good results.

Enzymes of *Aspergillus oryzae*

THE sequence of appearance of the enzymes liberated by *A. oryzae* during its growth and some of the properties of these enzymes have been described and discussed in a series of studies by W. G. Crewther and F. G. Lennox (*Austral. J. Biol. Sci.*, 6, 410, 428, 447; 1953). When a strain of the mould *Aspergillus oryzae* is grown in surface culture on a protein-free sucrose-tartrate medium, enzymes are released into the culture medium in the following order: first, the carbohydrases sucrose and amylase together with phosphatase; second, the proteases and esterases; and third, catalase. Their liberation is accompanied by the appearance of protein nitrogen in the medium and loss in weight of the mycelium. Evidence is presented for the presence of at least two proteases in addition to glycyglycine dipeptidase—one reduces the viscosity of gelatin very rapidly and is believed to act preferentially on the high-molecular-weight fractions of gelatin (the 'viscometric protease'), whereas the other degrades the lower molecular components of the gelatin more readily (the 'gravimetric protease'). The pH activity curves for sucrose and amylase also indicate the presence of more than one component. Inactivation of the various enzymes present during incubation at 40° C. and at different pH values has been followed. These papers also give a full account of the fractionation and preparation of crystals rich in protease and of the ethanol fractionation of enzymes at low ionic strengths.

Macromolecular Chemistry: Symposium In Italy

A SYMPOSIUM on macromolecular chemistry will be held in Milan and Turin during September 27–October 3 under the auspices of the Commission of Macromolecular Chemistry of the International Union of Pure and Applied Chemistry. Four subjects will be discussed at the symposium: characterization of polymers in relation to their technical properties (molecular weight and molecular-weight distribution, branching and cross-linking, and crystallization); building reactions of macromolecules; transformation reactions of macromolecules; and block polymers and graft polymers (preparation and properties). Papers will be considered for the symposium, written in French, English, Italian and German, and must be submitted before April 30; those covering the first subject should be sent to Prof. Antonio Nisini, Istituto Chimico, Università, Corso Massimo d'Azeglio 48, Torino, and those for the other three subjects to Prof. Giulio Natta, Istituto Chimico Ind. Politecnico, Piazzale Leonardo da Vinci 32, Milano, who together will be the editors of the publication of preprints and proceedings. The papers and discussions will be published in a special issue of *Ricerca Scientifica* which will appear shortly after the end of the meeting. People in Britain wishing to attend should write in the first place to the British National Committee for Chemistry, Royal Society, Burlington House, London, W.1.

Council for the Promotion of Field Studies

THE Council for the Promotion of Field Studies organizes a very large number of courses throughout the year which should appeal to many persons, both amateur and professional, with outdoor interests or hobbies. The courses are generally based on one of the Council's four field centres: Flatford Mill, East Bergholt, near Colchester, Essex; Juniper Hall, Dorking, Surrey; Malham Tarn, near Settle, Yorkshire; and Dale Fort, Haverfordwest, Pembrokeshire, with which is also associated the Skokholm Bird Observatory. The Council is particularly well known to naturalists of all descriptions, with specialized interests in the whole field of the plant and animal kingdoms; but the term 'field studies' goes well beyond the biological world, and those interested in, say, oceanography, geology, archaeology, geography, mapping and surveying, and meteorology will find their tastes catered for. Again, the standards are varied and range from the quite elementary to the advanced; courses tending towards the latter category are often run in conjunction with some other organization, prominent among which is the University of London. The field centres take about fifty persons at a time (many of whom can be accommodated in single rooms or cubicles), and there are well-equipped laboratories and basic outdoor equipment at each to keep the students fully occupied. The normal period of residence is one week, and the charge, which includes full use of the centre as well as board and lodging, is £5 15s. 6d. a week (Skokholm £4 14s. 6d.). Further information about each field centre and its courses can be obtained from the wardens at the above addresses, or from the Publicity Officer of the Council at Ravensmead, Keaton, Kent.

Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: T. Y. Watson

(director of agriculture, Uganda), secretary for agriculture and natural resources, Uganda; J. A. Burra (assistant conservator of forests, Windward Islands), assistant conservator of forests, Cyprus; A. M. J. De Swardt (senior geologist, Geological Survey Department, Nigeria), principal geologist, Geological Survey Department, Nigeria; P. B. N. Jackson (scientific officer, Northern Rhodesia), senior scientific officer, Northern Rhodesia; K. H. Bain (fisheries officer, Gold Coast), fisheries officer, Federation of Malaya; O. P. Wood (senior agricultural survey officer, Gold Coast), principal agricultural survey officer, Gold Coast; G. Stell, entomologist, Trinidad; A. R. Rees, awarded a Colonial research studentship with the view of appointment as a scientific officer (plant physiologist); F. J. Parker, veterinary officer, Uganda; R. J. Campbell, veterinary officer, Gold Coast; D. Clay, veterinary officer, Department of Agriculture, Jamaica; P. J. French, veterinary officer, Kenya; A. R. Mahood, entomologist, Veterinary Department, Nigeria; E. O. Trump, field zoologist, Veterinary Department, Kenya; J. L. Williams, statistician, East Africa High Commission.

Announcements

PROF. A. KASTLER, of the Faculty of Sciences, University of Paris, has been awarded the Holweck Medal and Prize for 1954 and will deliver the ninth Holweck Lecture in the rooms of the Royal Astronomical Society, Burlington House, London, W.1, on May 13, his subject being 'Les Méthodes Optiques d'Orientation Atomique et leurs Applications'. The Holweck Medal was founded by the Physical Society as a memorial to Fernand Holweck and to other French physicists who suffered or met their deaths during the occupation of France during 1940–44 and is presented in alternate years to a French physicist and to a British physicist, the recipient being a physicist distinguished for his work in experimental physics.

DR. J. R. NICHOLLS is retiring from the post of deputy government chemist on April 30 after forty-three years in the Department of the Government Chemist. His services are being retained in another capacity. His successor will be Mr. E. H. Nurse.

A WESTERN SECTION of the Society for Analytical Chemistry has recently been formed following an application signed by many members resident in the West of England, and the inaugural meeting will be held at noon on May 8 in the Lecture Theatre of the Technical College, Newport, Monmouthshire. After a business session in the afternoon, Dr. D. W. Kent-Jones, president of the Society, will address the Section on "Alcohol Determination and its Medicolegal Aspects".

THREE special summer courses will be held in the Massachusetts Institute of Technology as follows: June 15–25, developments in machine-tool technology (under Prof. M. C. Shaw, of the Machine Tool and Metal Cutting Division, Department of Mechanical Engineering); June 16–29, operations research as applied to solving industrial, business and government problems (under Prof. P. M. Morse, professor of physics); and August 23–September 3, automatic control of machine tools (under Prof. J. F. Reintjes, director of the Servomechanisms Laboratory). Application forms and further information on these courses can be obtained from the Summer Session Office, Room 7-103, M.I.T., Cambridge 39, Mass.

RADIO-METEOROLOGY

CONFERENCE IN TEXAS

A CONFERENCE on radio-meteorology was held in Austin at the University of Texas during November 9-12 last, sponsored by the American Meteorological Society, the Institute of Radio Engineers, the Radar Weather Conference, and the American national groups of Commission II of the International Scientific Radio Union and of the Joint Commission on Radio-Meteorology of the International Council of Scientific Unions. Some two hundred participants, widely representative of university, government and industrial scientific laboratories, attended the meetings.

The subject of radio-meteorology, which embraces several aspects both of the influence of meteorological factors on radio-wave propagation and of the use of radio techniques for studying features of the weather, has expanded greatly and increased in importance during the past few years. Work is still in progress in different parts of the world which is directed to the explanation of phenomena of which something was known twenty or more years ago; in addition, new fields of investigation, largely stimulated by wartime experiences in the operation of centimetre-wave radar, are being intensively pursued.

Tropospheric Wave Propagation

The conference was organized into eleven sessions, and the first four of these were concerned with the effects of the troposphere on the propagation of very short radio waves. The first paper, by T. J. Carroll, presented a review of existing knowledge of tropospheric propagation to points well beyond the horizon. Experiments during recent years have shown that, at such ranges of transmission, radio field strengths at very high frequencies are much greater and more reliable than have been predicted from standard theory. Of the explanations advanced to account for this phenomenon, there was considerable discussion of two, namely: that the fields are due to scattering of incident radiation caused by turbulent fluctuations of the refractive index of the atmosphere; and that the partial internal reflexion arising from the normal negative gradient of refractive index in the atmosphere is in itself sufficient to give fields of the order of magnitude of those observed. But it would appear that the explanation in terms of scattering by turbulent eddies finds the greatest support. Although it is felt that the scattering theory needs some refinement, it is not generally considered that the partial internal reflexion hypothesis has anything to offer towards such refinement; some account must ultimately be taken of the fact that the scattering centres are not spherical, which has so far been assumed to be the case.

Scattering of radio waves from a turbulent elevated layer formed the subject of a paper by W. E. Gordon, who said that airborne radio-refractometer observations in the United States indicate that such layers occur frequently. Within the layer the scale of turbulence is observed to be somewhat larger, and the intensity many times greater, than the values of these quantities observed above or below the layer. The scattered power from the layer received at certain distances may easily equal or exceed that from an atmosphere without such a layer.

Centimetre-wave refractometers are being exploited on an increasing scale in the study of the detailed refractive-index structure of the atmosphere, and these instruments have now been carried by aircraft to altitudes of 25,000 ft. Investigations of this nature were described by C. M. Crain and J. R. Gerhardt, by L. W. Cowan and by P. B. Taylor. The development of this form of refractometer as a new and sensitive instrument for the exploration of the refracting properties of the atmosphere of interest both to the meteorologist and the radio engineer, represents one of the most important steps of recent years in this field of study. Measurements of atmospheric refractive index have already been made over many coastal and interior regions of the United States for a wide range of climatic conditions. Airborne soundings have shown the existence of intense discontinuity layers which are not nearly well enough delineated by ordinary radio-sonde ascents. Examinations of turbulent structure show scales up to hundreds of metres with fluctuations of refractive index in the free air of the order of 10^{-4} (1 *M*-unit)—except in extremely turbulent layers where greater fluctuations are found—and decreasing as the altitude increases.

Considerable interest was shown at the conference in the properties of elevated layers in which the lapse-rate of refractive index with height is significantly greater than that appropriate to the standard atmosphere. Such layers, which usually occur at various heights below about 10,000 ft., play an important part in the determination of very-short-wave propagation characteristics. B. M. Fannin described the application of ray-tracing techniques to the evaluation of radio field-strengths in the presence of these layers, and P. B. Taylor discussed the effect of the layers on air-to-air propagation at very high frequencies in producing what has become known as the 'radio hole'. As two aircraft fly apart at a constant height above one of these abnormally refracting layers, it is frequently observed that there is a deep fade in the radio signal during communication between the aircraft. This 'radio hole' begins at a range of 50-200 miles, depending upon the heights of the aircraft and the layer, and continues out for a further 50-100 miles; beyond this the signal reappears in strength and rises, with intermittent fades, to levels well above the free-space value. Often a useful signal continues far beyond the normal radio-horizon. Some theoretical aspects of reflexion at elevated layers in very-high-frequency transmission between ground stations were outlined by F. H. Northover.

During the sessions on tropospheric wave propagation, a group of papers was presented by members of the staff of the Central Radio Propagation Laboratory of the National Bureau of Standards. Reviewing the programme of propagation research at the Bureau in the frequency band 100-1,000 Mc./s., J. W. Herbstreit said that the programme has included studies of terrain and meteorological effects on transmission loss within and beyond the line of sight. An important series of measurements is that being carried out with transmitters located at the Cheyenne Mountain Field Station, Colorado Springs, and with receiving points situated at various dis-

tances over the plains of Colorado, Kansas and Arkansas. B. R. Bean described the prolonged space-wave fade-outs within the radio-horizon which have been found to occur in these experiments at a frequency of 1,046 Mc./s. The occurrence of these fade-outs coincides with widespread nocturnal super-refraction, as evidenced by enhanced signals beyond the line-of-sight and ground modification of the refractive index profile. A paper on the meteorological instrumentation at the Mountain Field Station was presented by M. C. Thompson and K. O. Hornberg.

Climatic maps of the monthly average refractivity gradient have been drawn up for the United States for the hours of 03.00 and 15.00 G.C.T. These maps follow a regular climatic pattern, and the refractivity gradients have been correlated with the monthly median transmission loss of all available very-high-frequency propagation paths. The usefulness of this approach for the prediction of very-high-frequency transmission loss was discussed in a paper by B. R. Bean and Frances M. Meaney. Theoretical work at the National Bureau of Standards has sought to explain the observed propagation characteristics in terms of a modification of smooth-earth diffraction theory to include the effects of irregular terrain, climatic conditions, knife-edge diffraction and scattering in the turbulent atmosphere. It might perhaps be pointed out that much of the work of the Bureau in this field is designed to be of assistance to the Federal Communications Commission in the task of frequency allocation for various very-high-frequency and ultra-high-frequency services.

Other papers on tropospheric wave propagation were concerned with the prediction of diurnal field-strength variations at a frequency of 100 Mc./s. from synoptic data (by F. R. Bellaire and W. A. Arvola), a procedure which, although not yet fully explored, appears likely to prove fruitful; while L. J. Anderson and E. E. Gossard described attempts to deduce refractive index profiles within a surface duct over the sea from meteorological measurements at two heights only, and also the associated trapping of centimetre waves. The forecasting of propagation conditions from a knowledge of the synoptic situation also formed the subject of a paper by A. D. Hood and L. H. Doherty, in this case the aim being to predict the performance of a radar operating over Lake Ontario at a wave-length of 3 cm.

An account was given by C. W. Tolbert and A. W. Stratton of experimental observations on the transmission of 8-mm. waves over optical paths of various lengths up to fifty miles in which highly directive aerials were used. The signal-level was generally found to be in agreement with the free-space value corrected for absorption due to water vapour and oxygen in the atmosphere, although there were, as expected, fluctuations produced by atmospheric inhomogeneities over the path. Steady signals with small loss due to water droplets were experienced in fog, but severe attenuation was caused by showers of rain.

Thunderstorm and Tornado Atmospherics

The fifth session of the conference was devoted to the consideration of thunderstorm and tornado atmospherics, and the general problem of thunderstorm location from the observable characteristics of atmospherics. H. L. Jones described a programme of research which has as an objective the identification and tracking of tornadoes from observations of the

peculiar and abundant electrical discharges accompanying severe storms. It has been found that a line-squall, even though it appears as an extended echo on a radar screen, is composed of a number of separate storm centres each acting as a generator of atmospherics; further, as the intensity of an individual storm centre increases, the rate of arrival of atmospherics at a given receiving station increases. By observing the rate of arrival of atmospherics, and also the distribution of high- and low-frequency components, it is possible to classify storms according to their severity. The more severe storms and tornadoes are characterized by an arrival rate of 10 strokes/sec. or more, and a predominance of high-frequency components.

The recording and classification of thunderstorm atmospherics by counter techniques was discussed by M. M. Newman, J. R. Stehmann and J. R. Anderson, while E. R. Pierce and T. W. Wormell, in a communicated paper, described work at the University of Cambridge which shows that regular night-time atmospherics consist either of a series of peaked pulses fitting the concept of successive ionospheric reflexions or of a smooth quasi-sinusoidal oscillation that does not obey the simple reflexion picture. Regions producing quasi-sinusoidal wave-forms do not generate peaked atmospherics and vice versa, and all quasi-sinusoidal wave-forms observed at Cambridge originate from the south-west at distances exceeding 1,600 km. It was pointed out that observations near the eastern coast or the centre of the United States would assist in establishing the cause of these curious geographical effects.

The characteristics of the lightning discharge channel are important factors in the determination of the nature of atmospherics. The channel resistivity, its surge impedance, and the propagation velocity of the discharge all involve non-linear variations which lead to interesting stepped currents. It was shown by M. M. Newman how equivalent electrical circuits could be derived and used for the calculation of the currents in discharges; the currents so obtained are in good agreement with experimental observations.

What are believed to be the first P.P.I. photographs (pictures recorded on a cathode ray tube) that include information on atmospherics were presented by D. M. Swingle. This technique permits the detailed location of electrical activity among the radar storm echoes.

Cloud and Precipitation Physics

Cloud and precipitation physics were discussed in Sessions 6-9 of the conference. In a review of this field of study, S. E. Reynolds directed attention to the fact that observations have shown that it is unnecessary to invoke the Bergeron ice-crystal mechanism to account for certain types of precipitation occurring over much of the earth's surface. The development of precipitation particles without the intermediate stage of ice is well confirmed in tropical regions as well as in the middle latitudes for both coastal and inland areas.

The general characteristics of radar echoes obtained from various forms of precipitation were surveyed by Pauline M. Austin. A spherical rain-drop scatters radiation which is polarized in the same direction as the incident wave. For a non-spherical particle, however, some of the scattered radiation is cross-polarized, the proportion being dependent upon the shape, orientation and composition (ice, water or

Electrothermal Extraction Units reduce fire and explosion risks to absolute minimum

THESSE UNITS operate indefinitely without attention. Available for Soxhlet and other tests, for Kjeldahl and Micro-Kjeldahl digestions and distillations. **Electrothermal** apparatus operate without water, steam, gas, oil, or naked flame. Highly efficient heating elements in flexible, elastic glass fabric, give perfect heat transfer due to their close proximity to the vessel. Built-in controls give constant, accurate temperatures. Types produced for flasks—round, flat-bottomed or conical; for beakers and other vessels. A wide range of standard **Electrothermal** equipment is available from all laboratory suppliers—every unit guaranteed for 12 months. For special designs, literature, expert advice, phone or write now to **Electrothermal Engineering Ltd.**, 270 Neville Road, London, E.7 (GRANGEWOOD 0055).

Electrothermal turns on the heat for Science and Industry

1. Extraction Unit. 2. Kjeldahl Unit. 3. Micro-Kjeldahl
Electrothermal products are covered by British and foreign patents

New

ELECTRIC MORTAR GRINDER

This small mechanical mortar driven by a totally enclosed geared motor has been specially designed for the busy laboratory. It grinds any sample more quickly and thoroughly without effort, and can be left to run by itself.

Removable and interchangeable 150 mm. mortars and pestles are available in porcelain, toolsteel or agate—two scrapers are provided.

SHANDON SCIENTIFIC COMPANY

6, Cromwell Place, London, S.W.7—KNI. 1131

mixture) of the scatterer. Measurements made with different polarizations, or observation of the cross-polarized component, should therefore give valuable information concerning these quantities. Such measurements are especially desirable in the case of bright-band echoes, where the values of the average echo intensity are difficult to interpret. It was suggested that future research in this field may well follow two rather different lines. The first is technical in nature, and includes improvement in the extent and accuracy of the measurements, overcoming problems such as saturation of the receiver and extraneous fluctuations, and the development of the instrumentation for the quick and easy observation of such quantities as precipitation-rate and turbulence. The second type of research is related to the interpretation of the experimental data. There are, for example, many occasions where the presence of the bright band at a relatively low altitude prevents the estimation of rainfall from echo intensity except at very short ranges. This indicates the need for an empirical relation which involves not only the echo intensity and the rate of precipitation of rain, but also other pertinent quantities such as the height of the bright band, the range, and the beam-width of the antenna. A more complete analysis of the physical processes occurring within the bright band is also needed.

There is in progress in the United States and Canada a considerable amount of work on cloud and precipitation physics, and on the deduction from the nature of precipitation echoes of such factors as rainfall intensity, the growth and melting of snowflakes, and wind shear and turbulence. Other contributions to these topics at the conference were made by D. S. Johnson, with particular reference to rain from warm clouds in Hawaii; by P. M. Austin and R. Wexler on the subject of radar echo intensity at different levels in steady snow; and by K. L. S. Gunn, who presented radar evidence of a generating level for snow. In the last-named work a study of vertical radar records and upper-air data for twenty-two days of snow at Montreal has revealed that well-defined snow-trail patterns occur (on a height-range radar display) on days when the air aloft is stable. In these situations snow develops in discrete generating elements, of considerable lifetime, which exist in a layer of middle cloud. The top of this cloud is less than 200 ft. above a frontal surface on these stable days. At times when the warm air is unstable, the trail patterns are not so well defined, and the top of the cloud is farther from the frontal surface.

Further papers in the cloud physics section were those on the lowering of the bright band during heavy rain (R. Wexler and J. Honig), optical transmission through rain (D. Atlas), the deformation of large raindrops (J. E. McDonald), and the reliability of radar measurements of rainfall (F. A. Huff and J. C. Neill). D. Atlas also described some quantitative measurements at a wave-length of 1.25 cm. on the echo intensities of fog and rain. The echoes from light rain agree well with those calculated from the existing theory; but the measured intensities with heavy rain are a few decibels lower than the theory would indicate. An account was given by R. K. Moore of measurements made aloft of the distribution of drop sizes in thunderstorms by means of a shadowgraph technique.

J. S. Marshall discussed the manner in which the size distributions of raindrops may vary during the process of precipitation. In calculations relating to

this, it is assumed that the distributions as they originate in cumulo nimbus cloud, or at the melting-level, are like those observed at ground-level, but more consistent. Subsequent developments, when the drops are falling, by raindrop coalescence, cloud accretion and evaporation modify the distributions only to a small extent, so that any changes could scarcely be distinguished within the experimental accuracy of most observations. In the case of showers, wind shear can lead to a separation of the drops according to size: the resultant error in the measurement of rate of rainfall by radar, however, should diminish greatly when an average is taken either over a period of a few minutes or over an area of a few square miles.

Observations of rain echoes using a continuous-wave radar system operating at a wave-length of 8 mm. were described by D. G. Kiely, who also commented on some peculiar super-refraction effects noticed in transmissions at the same wave-length over a one-mile sea-path. In the rain-echo experiments a comparison was made between a radar system operating with a single aerial and one with dual aerials. The results show that the intensity of echoes is much less with a dual than with a single aerial system, but that there is a well-defined distance of separation between the aerials of a dual system beyond which greater spacing leads to little decrease in echo intensity. It also appears that fluctuations of the echo signal are not very dependent upon the rate of rainfall over a fairly wide range.

Operational Uses of Weather Radar

The last two sessions of the conference were devoted to papers on the operational uses of weather radar. The radar storm-detection programme of the United States Weather Bureau was outlined by V. D. Rookney, and from this it appears that although, as M. G. H. Ligda pointed out, little direct progress has been made during recent years on the utilization of radar storm observations for weather-forecasting purposes, more rapid developments in this field may be expected in the near future.

Considerable interest was aroused by papers dealing with the nature of radar echoes obtained when tornadoes are within range of observation, for any assistance in the issuing of warnings which leads to the reduction of damage caused by tornadoes is naturally of great importance in the United States. J. C. Freeman described observations of radar echoes from storms associated with tornado situations in Texas during the spring of 1953: these observations showed that three tornadoes were closely linked with very large and intense cloud-echoes, and in all these cases the large echoes were in a region of observable convergence of the surface winds.

A new theory concerning physical processes in the development of tornadoes was advanced by F. O. Roessmann. According to this theory there is no updraught in the funnel of a tornado, as is generally assumed, but on the contrary there is a strong down-draught, caused by moist labile conditions, which is stabilized by the revolving motion of the air mass in the funnel. It was further suggested that it might be possible to destroy a tornado by causing the explosion of a missile, guided by means of weather radar, at the appropriate point in the tornado, an idea which was supported by R. H. Mayer. The new theory produced much controversy and was clearly unacceptable to many members of the conference.

D. M. Swingle and L. Rosenberg, from a meso-meteorological analysis of radar weather observations in relation to the passage of cold fronts, showed that the use of a single radar in this way can lead to a worth-while improvement of short-term (two to six hours) weather forecasts for the local region.

If a criticism of the conference as a whole may be ventured, it is that too many papers (some sixty in all) were presented. It might have been more profitable if a more careful selection of papers to be read had been made, thus allowing more time for general discussion.

SIXTH INTERNATIONAL CONGRESS OF MICROBIOLOGY, ROME

REPORTS OF SYMPOSIA

THE papers presented at four of the six symposia held at the Sixth International Congress of Microbiology, Rome, have been published as supplements to the *Rendiconti dell'Istituto Superiore di Scienze**. The volume dealing with the Actinomycetes contains thirteen papers dealing with the morphology, classification and general biology of the group and will be of interest mainly to specialists. It includes three papers from S. A. Waksman's team at Rutgers University dealing with the subject from the antibiotic point of view, and one by H. G. Thornton and F. A. Skinner discusses the antagonism between Actinomycetes and other organisms in soil. D. Erikson contributes a study of mycelial variation. Views on classification are expressed by P. Negroni, A. R. Prevot, H. L. Jensen, G. Penso and E. Baldozi and his co-workers.

The volume on bacterial cytology is notable not only for its written content but also for the many excellent electron micrographs illustrating the papers. Special mention must be made of a hitherto unpublished photograph of a section of *Bacillus cereus* made by G. B. Chapman and J. Hillier, which illustrates Stuart Mudd's introduction, and the pictures accompanying W. van Itersson's paper on flagella. K. A. Bissett discusses the nature and importance of the cell envelope. Nuclear structures are dealt with in papers by E. Kellenberger, E. D. Delamater and R. G. E. Murray. S. Mudd presents his views on bacterial mitochondria, which are challenged by A. Winkler in another paper.

The third symposium, on microbial metabolism, contains important papers on protein synthesis by E. F. Gale and by J. Monod and M. Cohn, and a most interesting report on the study of *E. coli* metabolism from a genetic point of view by B. D. Davis.

It is a little unexpected not to find any discussion of protein metabolism included among the papers on interaction of viruses and cells, and most disappointing to find no illustrations of R. W. G. Wyckoff's views on electron microscope evidence of

virus proliferation. P. Lepine's paper is, however, very well illustrated with electron micrographs of ultra-thin sections of virus-infected cells, although perhaps not all virologists will agree with his interpretation of them. More controversial is G. Penso's postulated life-cycle of a mycobacteriophage. R. Dulbecco's account of his studies of animal viruses in tissue culture by his phage technique will be read with interest by all virologists, as will P. von Magnus's paper on incomplete forms of influenza virus. Plant viruses are discussed by F. O. Bawden, N. W. Pirie, and K. M. Smith and N. Xeros, while J. G. Carr contributes a short outline of the problem of virus reproduction in relation to cancer.

NATIONAL SCIENCE FOUNDATION

REPORT FOR THE YEAR 1952-53

IN the report of the United States National Science Foundation for the year ended June 30, 1953*, details are given of the support that the Foundation is continuing for three general long-range surveys of fields of science which are planned to require up to three years to complete. The survey of physiological science is being conducted by the American Physiological Society, and the final report is expected in the autumn of 1954. That of the development and status of psychology is being conducted by the American Psychological Association and comprises two major parts: an evaluation of the status of psychological knowledge, with special reference to general scientific methodology, development of theory, and dependence upon empirical laws; and an analysis of occupations in psychology, including the supply, demand and utilization of scientific manpower in the various branches of the science. The survey of applied mathematics is being conducted under the direction of the National Research Council Committee on Training and Research in Applied Mathematics in co-operation with the Defense Department.

Jointly with the universities, scientific societies and other government agencies in the United States, the Foundation sponsored eight conferences during the year, covering astrophysics, photosynthesis, the abundance and distribution of elements, high-energy physics, fibre bundles and differential geometry, methods of determination of steroids in blood and urine, specificity in development, and Lie groups and Lie algebras. Other conferences, symposia or meetings sponsored by the Foundation dealt with physics research in colleges, education in physiological science and the production and use of technical reports. Responsibility for maintaining a register of scientific and technical personnel in the United States was transferred from the Office of Education to the Foundation on January 1, 1953, and with financial assistance from the Foundation some ten to twelve scientific societies are setting up comprehensive registers which by June this year are expected to cover essential information on about a hundred thousand scientific workers and engineers. Registers for all main fields of science should be established by June 1955, and meanwhile information already collected is being analysed and reports are being prepared on specific scientific fields. The present report gives

an analysis of the type of employment of American scientists in 1951 and of their average annual salary.

Of 1,320 who obtained the degree of Ph.D. in mathematics, 88.0 per cent went into educational institutions, 6.1 per cent into government service and 5.9 per cent went into industry. For other subjects the statistics relate to Ph.D.'s and B.Sc.'s and are interesting in that the figures for the latter show a marked preponderance for industry as against educational institutes. The numbers, with the percentages going to educational institutes, government service and industry shown in brackets, are as follows: chemistry Ph.D.'s 11,568 (32.5, 7.4, 60.1) and B.Sc.'s 25,086 (4.8, 8.6, 86.6); chemical engineering Ph.D.'s 854 (30.1, 2.7, 67.2) and B.Sc.'s 8,251 (0.7, 4.1, 95.2); and physics Ph.D.'s 2,784 (58.4, 10.7, 30.9) and B.Sc.'s 1,365 (21.4, 23.9, 54.7). Average annual salaries were highest for graduates in chemical engineering; they were about equal for graduates in chemistry and in physics, with mathematics and psychology appreciably lower and approximately equal. Except for physics, where salaries in Government service and in industry, at least at the doctorate level, tended to be equal, average salaries were highest in industry and lowest in educational institutions.

During the year the Foundation made 173 grants totalling 1,698,150 dollars for the support of basic research in the biological, medical, mathematical, physical and engineering sciences at 85 institutions. Seventy-two of these grants, totalling 798,800 dollars, were for biological and medical research, and a hundred, totalling 866,550 dollars, were for research in the physical, mathematical and engineering sciences, chemistry (28, totalling 206,500 dollars) and physics (22, totalling 282,400 dollars) receiving the greater part. The conference on physics research in colleges, already noted, recommended that, in evaluating proposals, besides the intrinsic significance of the proposed research, emphasis should be placed on the probable value of the project to the educational work of the institution. It was also suggested that projects which involve the participation of students should be encouraged and that due weight should be given to the promise and ability of the principal investigator.

In further illustration of the Foundation's understanding of basic research, the report gives a number of examples of investigations currently supported. Of the type involving observation and description are B. Maguire's exploration of the botanical resources of the Guayana Highland of British Guiana, S. D. Durrant's study of mammals on the Aquarius Plateau in the Henry and Abajo Mountains of Southern Utah, and T. H. Bullock's study of the pit organ of pit vipers. Among investigations concerned with the development of tools and instruments are M. Jakob's study of bubble formation, heat flow and other aspects of boiling, explorations of the upper atmosphere at the Ionosphere Research Laboratory, Pennsylvania State College, and the construction and operation of a radio telescope at Harvard College Observatory, under the direction of B. J. Bok. In the field of measurement, grants have been given for investigations of an unchanged component of cosmic radiation called *N-rays*, believed to be mostly high-energy neutrons. Several research projects which involve the design of suitable models for dealing with difficult problems were also being supported: these include a laboratory model of the photosynthesis of sugar and cellulose and of the biochemical reactions

responsible for the luminescence of fireflies. Grants for the development of concepts include one for the development of a new conceptual basis for probability, and those for testing concepts include a grant to study regeneration of tissue (particularly to attempt to find a growth-inhibiting substance in the adult tissue) and one to test the assumption that cosmic radiation has been constant during the past thirty thousand years by measuring the radioactive carbon content in sediments at the bottom of the ocean.

Of the 557 fellowships awarded for the academic year 1953-54, 42 were made to post-doctoral candidates and 175 to those who had received awards in 1952-53; 180 went to first-year graduate students, 166 to those in their second year, and 169 to those in their final pre-doctorate year. Chemistry claimed 129 fellowships, physics and astronomy 115, engineering 63, mathematics 56, zoology 38, biochemistry 35, geosciences 26, botany 19, microbiology 18, geophysics 14, medical sciences 14, genetics 11, psychology and anthropology 10, and agriculture 9. In view of the increasing number of applications (3,300 as against 3,000 in 1952-53) the Foundation published an 'honourable mention list' of 1,274 applicants.

During the five years 1948-52, bachelor's degrees in science, engineering and agriculture totalled about 95,000 a year, and doctor's degrees in the same fields 4,660; for 1953-57 the comparable estimates are 66,800 and 5,420, respectively; but it is expected that the downward trend will be reflected in doctorate awards from 1956 onwards. Graduate enrolment at the first year in all fields of science fell from about 12,000 during 1951-52 to about 8,000 during 1952-53. So far, the Foundation has not asked Congress for funds to support a scholarship programme but is attempting to increase the supply of young scientific workers by improving the teaching of science. The Foundation has also established an Advisory Panel on Scientific Information, and preliminary inquiry suggests that the most important information in unclassified research reports reaches scientific workers through established publication channels.

ROYAL SCOTTISH FORESTRY SOCIETY CENTENARY VOLUME

THE Royal Scottish Forestry Society is the oldest forestry society in Great Britain (the English Society having been founded in 1881), and this year it is celebrating its centenary. In honour of the occasion, the Society proposes to issue four special numbers of its journal, *Scottish Forestry*, as a centenary volume, each number containing three articles which will deal with all the aspects of forestry, and the first of these numbers has recently been published (*Scot. For.*, 8, No. 1; January 1954). It opens with centenary greetings from the president of the Society and of the English Society, the chairman of the Forestry Commission, Lord Radnor, the chairman of the Empire Forestry Association, and the president of the Society of Foresters of Great Britain, and then goes on to the three articles: the history and activities of the Society, 1854-1953, by the honorary secretary of the Society, Sir Samuel Strang Steel; forest policy and legislation affecting Scotland, 1854-1953, by Sir Henry Benceford Pierce,

of the Forestry Commission; and private forestry in Scotland, by Sir John Milne Home.

The first article recalls how the original president of the Society was James Brown, at that time deputy surveyor of the Forest of Dean and provisional head forester of Armiston, who is chiefly known as the author of "The Forester", the standard book on forestry at that period. The Society was formed by a strong committee of nineteen which framed its constitution and its by-laws, subscriptions and so forth. Members were soon forthcoming, and the first *Transactions* of the Scottish Arboricultural Society, as it was then called, appeared four years later. During the past century the Society was constantly pressing the claims of forestry in Scotland on the Government, and committees and commissions were appointed by the House of Commons, without, however, much practical result until the present century.

In Sir Henry Beresford Pierce's well-informed article he points out that it was the Society (and, in particular, Munro Ferguson, afterwards Lord Novar, Sir John Sterling Maxwell and Lord Lovat) which pressed the Government to form a model State forest to be a pilot scheme to a much larger proposal that the Society put forward, namely, the afforestation of between three and four million acres in Scotland. As a practical outcome of this suggestion, the Royal Commission on Coast Erosion in 1909 proposed alternative schemes for the afforestation of nine million or six million acres in the United Kingdom. It was the First World War which eventually brought these ultimate schemes to a head in the Aoland Report and the Government Bill forming the Forestry Commission at the close of the War.

The Society may be congratulated on the proposed centenary volume, for in that should be assembled the true forestry history of the period and the ideas which make for an appreciation of what forests and forestry really imply to a country and its people.

E. P. STUBBING

ADAPTIVE CHANGES IN SUNFLOWER

G. E. BLACKMAN AND G. L. WILSON have continued their physiological and ecological analyses of plant environment by investigating the adaptive changes in the vegetative growth and development of *Helianthus annuus* as induced by alterations in light-level (*Ann. Bot.*, 18, No. 69, 71; 1954). To this end pot experiments were carried out in which sunflowers in the early vegetative phase were first grown for a period under three levels of light (1.0, 0.5 and 0.24 daylight). Afterwards, pots from each light-group were subdivided into three so that in a second period plants could be subjected to the nine possible combinations of the same three light-intensities before and after transference. During the post-transference period of adaptation to either a higher or a lower intensity the net assimilation-rate was found to be logarithmically proportional to the light received and there was no residual effect of the initial light treatments. Eight days after transference the leaf-area ratios (total leaf area/total plant weight) at each light-level became adjusted to a new equilibrium irrespective of the large initial differences in the ratio induced by the pre-transference intensities. In both periods there was an inverse and logarithmic relationship between the leaf-area ratio and falling

light-intensity; consequently, the greater the degree of shading in the pre-transference period, the higher were the mean ratios in the second period. Since the relative growth-rate is the product of the net assimilation-rate and the leaf-area ratio, the variations in the leaf-area ratio in the post-transference period induced by the initial light treatments were reflected in the relative growth-rates. Thus plants transferred from a lower to a higher light-intensity were leafier and initially grew faster than plants maintained at the higher level in both periods: the converse conditions led to a reduction in the growth-rate.

It was observed that shading depresses the growth of the roots, but that the relative growth-rate is dependent on the light-intensity in both the pre-transference and post-transference periods. The growth-rate was maximal when plants were moved from the lowest to the highest intensity.

In terms of leaf weight, decreasing the light-intensity decreased the relative growth-rate and there was no consistent after-effect of the initial light treatments. The rate of expansion in leaf area tends to be highest at the intermediate level of 0.5 daylight, and over all the post-transference intensities the rates were maximal for those plants which received initially full daylight. The ratio of leaf area to leaf weight was inversely and logarithmically proportional to the light-level. After transference, the slopes of the regressions were independent of the initial light treatments; but the mean ratios were inversely correlated with the initial degree of shading. These observations are discussed with particular reference to the control of growth exerted by growth-regulating substances: on the basis of existing knowledge, no adequate interpretation of the adaptive changes yet seems possible.

DISTRIBUTION OF LAMINARIACEAE AROUND SCOTLAND

By F. T. WALKER

Institute of Seaweed Research, Musselburgh, Midlothian

FIFTY-NINE detailed surveys, covering 80,000 acres of the sub-littoral zone off the north-east, south-east and south-west mainland of Scotland, the Isle of Skye and several of the islands of Orkney, have been completed by the Botanical Division of the Institute of Seaweed Research.

The detailed surveys were preceded by aerial photogrammetric surveys. They were carried out at all times of the year and during seven years, 1946-53, and so include seasonal and cyclic changes. They covered areas of the sea-bed from low-water mark down to ten fathoms (19 m.), where the dominant species was either *Laminaria cloustoni*, *L. digitata* or *L. saccharina*. (Some surveys were restricted to depths of 1-6 fathoms.) Tidal streams ranged from 0 to 7 knots and tides from low-water mark to 3 fathoms (6 m.) according to time and location.

In the course of the fifty-nine surveys, operated from motor-vessels, some 50,000 quadrats were taken from the sea-bed by means of calibrated spring-grabs which close by trigger action on reaching the bottom.

The 1946-49 surveys employed methods of quadrat sampling along transects measured by range-finder,

The master means of fresh weight (vertical lines) and percentage cover (horizontal lines) of *Laminaria* found at 1-10 fathoms low-water mark ordinary spring tides, from the data of 59 surveys around Scotland between May 1946 and September 1953

while for the 1949-53 surveys, random sampling was used. Random sampling is less dangerous inshore; nevertheless, this method can attain considerable accuracy: standard errors of 1-2 per cent of the mean, when the intensity of sampling is only 100 quadrats per square kilometre, have been achieved.

The mean of the means (which we term the master mean) of 'density' and 'cover' found at each depth for the fifty-nine surveys is given in Table 1 and in the accompanying figure.

Density is the average fresh weight of *Laminaria* per unit area based on quadrats which contained these algae. Cover is the number of quadrats which contained *Laminaria* expressed as a percentage of all quadrats.

From the above data, several conclusions may be drawn. First, it will be found that the value for density divided by the respective value for cover is a good approximation to a constant (13.14) for each fathom interval of depth of 1-10 fathoms. The density/cover values for the ten depths have a standard deviation of 0.9 and a standard error of 2 per cent from the constant. The fresh weight of *Laminaria* is therefore proportional to the percentage cover. This relationship has been reported for many individual surveys²⁻⁴.

Secondly, the seaweed densities given in Table 1 follow an exponential scale. The regression of this scale with increasing depth calculated on $\log_{10}$ is $1.1600-0.0770$ per fathom, from 1 to 10 fathoms, low-water mark ordinary spring tides. As the cover

Table 1

Depth Low-water mark ordinary spring tides (fathoms)	Density		Cover Master mean of 59 surveys (per cent)
	Master mean of 59 surveys (based on quadrats with <i>Laminaria</i>)		
	(lb./sq. yd.)	(kgm./sq. m.)	
1	11.0	6.0	76
2	10.8	5.6	72
3	8.8	4.8	65
4	7.5	4.1	57
5	6.2	3.3	48
6	5.3	2.9	44
7	4.7	2.5	35
8	3.8	1.8	28
9	2.7	1.5	21
10-1	2.3	1.2	18

Table 2

Depth Low-water mark ordinary spring tides (fathoms)	Cover Master mean of 59 surveys (per cent)	Standard deviation of mean density Master mean of 59 surveys	Standard deviation Cover
1	68	5.20	7.6
2	66	4.73	7.3
3	58	4.30	7.4
4	51	3.68	7.1
5	45	3.07	6.8
6	39	2.43	6.2

is proportional to the density, then the cover must be exponential also with depth.

Seaweed growth is the result of photosynthesis. If light be the limiting factor we would expect the growth of *Laminaria* to be exponential with increasing depth, for the coefficient of extinction of the visible solar spectrum is also logarithmic through water.

The 'coefficient of extinction of *Laminaria*', based on the exponential scale $\log_e$, equals 0.096 per metre interval of depth.

The area covered by the species of *Laminaria* has been shown above to be proportional to the density or fresh weight at various depths; cover, then, should be proportional to the standard deviation of the mean density where the frequency and the spread of the quadrat weights follow normal distributions.

The standard deviation of the mean density has been calculated for twenty-eight of the surveys, carried out between 1949 and 1953, when random sampling was employed. The master means against the corresponding values for cover are given in Table 2 from 1 to 6 fathoms.

It will be found that the values in Table 2, col. 4, equate as follows: standard deviation of the mean divided by the percentage cover equals $3.1-0.3$ fathom (± 3 per cent), or the standard deviation is closely proportional to the cover. From this it may be concluded that the algal cover is conditioned by the frequency and spread of the algae, which in turn are the result of photosynthesis-reproduction-dispersion; while the nature of the substrate plays an important part in the establishment of algae, the areas under review were selected because they did support prolific laminarian growth.

In more recent surveys the number of plants per quadrat has been recorded, and the decrease in seaweed density has been found to be more the result of a reduction in the number of plants per unit area than of the weight of individual plants. It follows that with increasing depth the total spore production will be decreased, dispersion and fertilization will be restricted and the plant cover limited.

This last conclusion requires the development of the spores to proceed at approximately the same depth of sea as that at which the parent plant is or was growing.

Time has been available for the analysis of only a limited number of surveys by the application of the chi-squared test to samples and their distributions. The data of some surveys fit normal distributions admirably, others do not. For example, a survey carried out between Girvan and Bannane Head in the approaches of the Firth of Clyde during May 1952 indicated that the frequency and spread of the samples had a normal distribution at all depths from 0 to 6 fathoms. An identical survey, carried out in the following October-November after severe gales had

reduced the total quantity of seaweed by more than 34 per cent, showed the samples no longer conformed to normal distributions when the χ^2 test was applied.

The aerial survey of the sub-littoral zone of Scotland (begun in 1945) in conjunction with the results of the detailed surveys have enabled me to assess the total laminarian growth from aerial photographs taken by the Royal Air Force, to which grateful acknowledgment is made for its co-operation.

The first assessment was made in 1950, and a reassessment in 1954 shows no extensive changes, although it is now known that cyclic changes are occurring. These will be reported later.

The marine coast of Scotland and Islands is 5,300 miles; the sub-littoral zone from low-water mark to a depth of ten fathoms is two million acres; over this area, with considerable variation in seaweed density, grows 10 million tons (fresh weight) of Laminariaceae. Of this quantity, 3-4 million tons are concentrated in quantities of economic value.

UPTAKE OF RADIOACTIVE CARBON AND PHOSPHORUS BY PARASITIZED LEAVES

By DR. M. SHAW

Department of Biology, University of Saskatchewan
and

DR. STEWART A. BROWN and
DR. D. RUDD JONES*

Prairie Regional Laboratory, National Research Council,
Saskatoon, Sask.

THE arbitrary nature of the distinction between 'obligate' and 'facultative' parasites on plants has long been recognized, as well as the possibility that advances in knowledge might lead to the successful culture of the former, including rusts and mildews, on artificial media¹. Indeed, this has apparently now been accomplished in the case of *Gymnosporangium juniperovirginianae* Schw., a rust producing telial galls on *Juniperus*². Nevertheless, relatively little is known about the physiology of rusts and mildews and their effects on host metabolism, or of the physiological basis of resistance to them. Both obligate and facultative parasites cause marked increases in the respiration of the host tissues, even at considerable distances in advance of the invading mycelium, a phenomenon which may be attributed to the production of diffusible substances by one or both members of the host-parasite complex³. Eventually photosynthesis is reduced, and there is usually a visible chlorosis in the area of infection. An outstanding characteristic of rusts and mildews on cereals is that increased respiration⁴ and decreased photosynthesis are accompanied, in the earlier stages of disease, by increases in hexose, sucrose, starch⁵, free amino-acids⁶ and, to judge from the occurrence of oil droplets, possibly in

lipid content as well. Often the only starch to be found in the mesophyll of wheat leaves occurs as a deposit around infections of these fungi. Under optimum conditions, the host tissue at infection sites flourishes long after the remainder of the leaf is moribund, and there may even be a resynthesis of chlorophyll⁷, leading to the formation of the characteristic 'green islands'.

Gottlieb and Garner⁸ demonstrated the movement of phosphorus-32, supplied to the culture solution as phosphate, to infections of *P. graminis* on wheat. In their experiments the plants were exposed to the isotope for several days. The specific activity of the ureidospores was less than that of either healthy or infected leaf tissue. Yarwood and Jacobson⁹ described the preferential absorption of sulphur vapour by infections of *Uromyces phaseoli* on bean and sunflower and *Erysiphe polygoni* on bean after eight-hour exposures to sulphur-35. The treatment was lethal to the fungi but did not damage the leaves.

The isotope technique appeared to offer an approach to the investigation of the relation between diseased and healthy tissue on the same leaf. Accordingly, we examined the effect of infection with a number of facultative and obligate parasites as well as of mechanical wounding on the distribution of phosphorus-32, supplied as phosphate, and of carbon-14, fed to the leaves as carbon-14 dioxide or sugars (glucose-1 ¹⁴C, ribose-1 ¹⁴C, xylose-1 ¹⁴C) under a variety of conditions. The sugars and phosphate were introduced either by localized injection of attached leaves or by standing the cut-leaf bases in 0.25 per cent (w/v) solutions in distilled water or phthalate buffer at pH 5.5 for from 20 min. up to 24 hr. The leaves were then killed between hot metal plates, pressed and autoradiographs prepared using Kodak No-Screen X-ray film.

In uninfected leaves fed with labelled sugars or phosphate, tissue wounded by pricking or removing the epidermis was sometimes as active as that in undamaged areas, but usually less so. No tracers entered areas which were actually dead. Similarly, no activity entered or accumulated around the lesions produced on *Vicia faba* by *Botrytis* sp., which kills the host tissue in advance. Moderate accumulation was observed in young infections and around, but not within, older infections of *Pseudomonas medicaginis* f. sp. *phaseolicola* (Burkholder) Dowson, on *Phaseolus vulgaris*. There was no accumulation in young infections of *Helminthosporium* sp. on wheat and actually less radioactivity (from glucose) in young lesions produced on oats by *Pseudomonas coronafaciens* (Elliott) Stapp than in surrounding healthy tissue. After 20 hr. a diffuse zone of increased activity was observed around old, large, lesions of *Helminthosporium* on wheat, as at the edges of cuts made transversely across the lamina. In short, the results obtained with these facultative parasites showed a general similarity to those obtained by the mechanical wounding of healthy tissue. It is clear, however, that the range of facultative parasites investigated should be extended to include types more closely approaching obligates in their behaviour.

The results obtained with rust (*P. graminis* on wheat and barley and *P. helianthi* on sunflower) and mildew (*Erysiphe graminis* on wheat and barley) were more striking than those described above. From an early stage (3-4 days after inoculation) of development on susceptible hosts, there was a rapid and marked accumulation of radioactivity at infections of these obligate parasites, as illustrated in Figs. 1-2

* N.R.C. Post-doctoral Fellow, 1952-53. Now at Imperial Chemical Industries, Ltd., Butterwick Research Laboratories, Welwyn, Herts.

Figs. 1-2. Autoradiographs of excised wheat leaves with 12-day old infections of *P. graminis*. At this stage of development the starch deposit lies outside the secondary uredinia (see Fig. 6). (1) After feeding 0.25 per cent xylose-1 ^{14}C for 45 min. (2) After 165 min.; the activity is concentrated beneath the uredinia. In all figures light areas indicate high activity.
Figs. 3-5. Autoradiographs of sunflower leaves, bearing 8-day old infections of *P. helianthi*, exposed to carbon-14 dioxide for 3 min. at a light intensity of 500 f.c. Total concentration of carbon dioxide approximately 0.03 per cent. (3) Killed immediately. (4) Killed after standing in a normal atmosphere for 20 min. (5) Killed after 4½ hr.
Fig. 6. Starch formation in wheat leaves infected with *P. graminis*. The leaves were cleared in alcohol and stained in aqueous iodine

for *P. graminis* on wheat. Identical results were obtained with glucose, ribose and xylose and phosphorus-32. Following exposures to carbon-14 dioxide in the light for 0.5-3 min., leaves were killed immediately, and also after standing in a normal atmosphere for varying periods of time. Autoradiographs revealed the effect of the parasite in depressing photosynthesis in the invaded host tissue and the subsequent influx of fixed carbon-14. A typical result is shown in Figs. 3-5 for *P. helianthi* on sunflower.

By removal of the ectoparasitic mycelium of mildew both before and after exposure to the isotopes, it was possible to demonstrate that the bulk of the accumulated activity was in the mesophyll of the host, beneath the fungal mycelium. Moreover, accumulation was not detectably impaired by removal of the mycelium prior to the experimental treatment. The 'active' nature of the process is emphasized by the results of preliminary experiments with both rust and mildew in which marked inhibition was obtained with phloridzin (1 mM) and dinitrophenol (1 mM) in phosphate buffer⁹ at pH 5.5. Little inhibition was observed with azide (10 mM) under these conditions. Allen and Goddard¹⁰ reported that the mildew-stimulated respiration of wheat was insensitive to azide, which did, however, inhibit the respiration of the fungus itself.

Accumulation was much more pronounced with susceptible- than with resistant-type infections of rust and mildew. This cannot be regarded merely as an expression of the degree of utilization of substrate by the parasite, since the increase in activity is mainly in the mesophyll of the host. Similarly, under summer greenhouse conditions starch was deposited in association with susceptible but not with resistant infection types. Even with the former, no starch formed under winter greenhouse conditions at Saskatoon. Starch formation, formerly attributed to a breakdown in translocation¹¹, is probably also the result of translocation to the infection. An interesting point is that, in the case of rust, the starch is deposited as a very distinct ring. In young infections this closely surrounds the uredinia but later becomes separated from them by a starch-free zone (Fig. 6).

It is essential for successful obligate parasitism that substrates be supplied to the invaded cells at a rate high enough to maintain their organization and metabolism in the presence of the parasite, which cannot exist on dead tissue. Whether or not the parasite obtains an adequate supply of substrate for

continued growth must depend on the relative rates of utilization and supply (transport) of substrate. It may be imagined that in resistant hosts the latter limits the growth of the fungus initially, and that subsequent exhaustion of the invaded host cells and suboptimal nutrition of the fungus result in the formation of metabolic products, by one or both members of the complex, which would not otherwise be formed in critical amounts. These may well be toxic to either or both parasite and host. Injury to the invaded host cells may also stop all translocation to and from surrounding healthy areas, as is the case with at least some facultative parasites. A parasite-induced increase of permeability of the type reported by Thatcher¹² does not appear capable of explaining the active transport described here.

Our observations support the hypothesis that a substance (or substances) diffusing from the site of infection alters the normal metabolism of the host tissue. The concentration of this substance, as controlled by rates of production, breakdown or inactivation, and diffusibility, may be regarded as governing the rate at which metabolites move into the infection from surrounding areas and thus the supply of substrate to both parasite and parasitized cells. It seems apparent that the rate of movement of substrates both toward and away from the primary infection must play an important part in determining susceptibility to disease, at least in the case of obligate parasites.

These observations, which will be published in detail elsewhere, form part of a programme of research on the physiology of parasitism financed by grants (to M. S.) from the Department of Agriculture and the National Research Council. We are grateful to Dr. A. O. Neish for providing the labelled sugars, to Prof. J. W. T. Spinks for a gift of phosphorus-32, and to Dr. W. A. F. Hagborg for cultures of the bacterial pathogens. [Dec. 31.]

Science Teachers in Schools

As a member of the Appleton Committee considering the shortage of teachers of science and mathematics in Scotland, I have read with very great interest the editorial comments in *Nature* of January 30, p. 177. I have found the comments of great interest and value. There is, however, one small passage of which the implication is not too clear. The passage in question states: "Are not these small science sixth forms due partly to the fact that some of the science teachers are of such moderate ability and personality that they cannot attract any more pupils to their side of the school, and partly to the fact that, where the teacher is competent, he has already attracted all the pupils capable of doing sixth-form science?"

Surely the two possibilities visualized here are rather contradictory. In one case it suggests that the smallness of the science classes is due to incompetence on the part of the science teachers. If this is the case, the obvious solution is to improve the quality of the science teachers. If, however, the second possibility is true, improvement of the quality of the science teachers would be of no avail. However competent the science teacher he cannot teach the subject to pupils incapable of absorbing it, and the problem is impossible of solution. After all, you cannot make a silk purse out of a sow's ear. I may, however, have misunderstood the implication of this passage.

I also note that the National Advisory Council suggests that "the glamour of research should be counteracted by putting the case for teaching as a satisfying career to undergraduates in the pure science departments of the universities". While I agree that too many unsuitable people are attracted by the glamour of research, I am appalled by the suggestion that those responsible for advising undergraduates should be expected to pretend that teaching is a satisfying career if this is not in fact the case.

In Scotland, great emphasis is laid upon the desirability of science teachers holding first- or second-class honours. While agreeing that teachers should be of the best quality, I cannot agree that the holder of first- or second-class honours is likely to be a better teacher than a man holding a good pass degree. In fact, I feel that the honours man tends to be a narrow specialist, whereas a schoolmaster should be a man of broad general culture. It is surely not necessary to hold a first- or second-class mathematics degree to teach quadratic equations. I have been assured by a professor of mathematics in a Scottish university that it is the realization that they will not use their academic knowledge to the full which creates a reluctance of honours graduates to go in for teaching.

In conclusion, I should like to say that I heartily agree with the last paragraph of the article. Legislation on education of the past twenty years or so has

been too much the prey of the popularity-seeking politician.

Feb. 3.

Nature's campaign to promote action on the part of the various authorities concerned with the future of science and science teaching is admirably persistent and constructive. One of the suggestions (*Nature* of February 27, p. 388) is of particular interest. It reads as follows: "If more of the graduates in arts, for example, left the universities of Britain with some sound knowledge of general science, they might well be qualified to assist in the general science teaching which is so desirable for the ordinary citizen, whether or not he proceeds beyond the grammar school or technical school level". This is an admirable idea which I should be delighted to see carried out as an educational policy; but it is well to examine the difficulties that lie in the way to see if they can be surmounted.

First of all, let us take a historical fact. More than thirty years ago, in one university at least, intending teachers entering the faculty of arts were compelled to take either mathematics or science as part of their studies if they had not included Latin in their matriculation. The result was not happy for those taking compulsory science. Lecturers and demonstrators were not particularly interested in students who were pursuing subjects that were regarded as makeweight. The students themselves felt they were intruders or 'poor whites'. The scheme was not continued. It would be folly to make further attempts along the same lines.

Secondly, let us deal with general science—an admirable conception, rarely if ever realized. If general science is ever to become, what it should become, the peer of English as the main educational discipline for children of school age, the organization will have to start in the universities; but this will need men and women imbued with the fervour and enthusiasm of a T. H. Huxley. It will need in its pioneers a combination of humanist, philosopher and scientist, together with willingness to sacrifice possible fame as scientific discoverer to the more humble reputation of teacher. If such a discipline could be instituted to reach down from the universities to the schools and outwards from the schools to all human activities, it would, in the words of the article, facilitate "the absorption of science into the general culture . . . and it would also assist the graduate science teachers to concentrate more on the sixth forms or the teaching of those with a scientific career in mind". However, it is unlikely to succeed unless general science becomes as important in general esteem as particular scientific studies.

The arts graduate is already in danger of becoming a poor relation because the science graduate is attracting an inordinate proportion of special posts in the schools. This regrettable tendency to devalue the arts degree is already having unhappy results and can lead only to ill-effects on our general culture.

Solar Radio Asymmetry at 4-Metres Wave-length

In 1948, Hey, Parsons and Phillips¹ reported that at 4.1-metres wave-length bursts of radio emission, usually of a few minutes duration, occurred more often in association with flares on the eastern half of the sun's disk than on the western half. Subsequent observations have confirmed this conclusion. In a recent analysis of radio emissions at 1.5-metres wave-length, Dodson, Hedeman and Owen² could find no evidence of this asymmetry. The following reasons may explain why they failed to observe the effect.

Hey, Parsons and Phillips¹ suggested that the asymmetry they had observed might be due to radio absorption in ionized solar corpuscular streams, as the rotation of the sun causes the envelopes of such streams to drift eastwards relative to the active solar regions from which they emanate. They also pointed out that the longer the wave-length, λ , the greater would be the expected absorption. That this anticipated property provides a test of the absorption theory was emphasized by Unsöld and Chapman³.

As the absorption coefficient is proportional to λ^2 , it is approximately 7.5 times greater at $\lambda = 4.1$ metres than at $\lambda = 1.5$ metres. Further, if the electron density in the stream is sufficient, the refractive index, μ , may be appreciably less than unity at long wave-lengths, and the absorption coefficient would again be increased since it is inversely proportional to μ ; in addition to this, refraction might be expected to diminish radio intensities in the direction of the ionized streams by deviating the long radio waves out from them. It is consequently to be expected, on the hypothesis that solar radio asymmetry at $\lambda = 4.1$ metres is due to asymmetrical absorption in an ionized stream, that the asymmetry might be difficult to detect at the shorter wave-length of 1.5 metres. The results reported by Dodson, Hedeman and Owen are therefore in accordance with this hypothesis, although the conclusion can scarcely be regarded as decisive yet as they analysed only about two hundred flares with associated radio measurements during 1948-50, whereas we found that ten times this number of observations obtained during 1947-50 were only just sufficient to establish the significance of the asymmetry at $\lambda = 4.1$ metres at the 5 per cent level of chance probability.

Additional data at $\lambda = 4.1$ metres obtained during part of 1948 and the first half of 1951 have increased the significance of the asymmetry observed at this wave-length. It is unfortunate that, owing to interference and other circumstances, radio measurements had to be discontinued in 1951, because a striking feature is the pronounced increase in the asymmetry during the second half of 1950 and the first half of 1951, just when the recurrent *M*-type magnetic storms were becoming prominent. This suggests the intriguing possibility that continuous *M*-type corpuscular streams may be more effective in producing absorption than are the spasmodic bursts of corpuscular emission from active flare regions.

A detailed analysis of the radio asymmetry with respect to terrestrial magnetic activity is now in progress. It is hoped that this may be decisive in establishing whether or not the interpretation in terms of the absorption of a corpuscular stream is correct. There is so little direct evidence of solar corpuscular streams, and especially of the nature of

solar *M*-regions, about which there is yet uncertainty whether the terrestrial magnetic activity might be due not to corpuscular streams but to ultra-violet radiation, that any evidence which can be derived from radio phenomena is of importance.

Time of Flight of 14.1-MeV. Neutrons

THE essential problem in utilizing the time of flight of fast neutrons for energy measurements is the rapid fall-off in efficiency of detection as the flight path *D* is increased, since the resolution is proportional to *D*, while the efficiency is proportional to *D*⁻². It is therefore desirable that a multi-channel time spectrometer be used when a neutron momentum spectrum is being analysed.

One such instrument is the high-speed triggered oscilloscope in which the first pulse triggers off the time base and the second pulse is displayed on the 'y' plates. Using a new form of high-speed time base and low-level trigger circuit¹, the group of pulses due to the 14.1-MeV. neutrons from the reaction ⁴He(*d*, *n*)⁴He has been analysed. A full account of the technique will be published later; but it is felt that a preliminary indication of the feasibility of the method and indeed of the accuracy of the analysis even with such high-energy neutrons will be of interest. The graph shows the number of pulses falling in each division of the time base which is triggered from the recoil ⁴He detected in a stilbene crystal. The neutrons travel about five metres and into six cubic inches of toluene/terphenyl solution. By moving the toluene bottle towards the target, the shift observed in the peak is in agreement with that calculated from the neutron energy. The optimum resolution is less than 10 μ sec.² and is obtained by adjusting the biases on the two low-level discriminators. At this setting most of the neutron pulses overcome the bias.

Although the high-speed time-base is invaluable in setting up the apparatus, it is tedious to estimate the

time distribution on it. An electronic circuit is therefore being developed to convert a time spectrum into a voltage spectrum, which will then be fed into a multi-channel kick-sorter.

I am indebted to Dr. P. J. Grant, Dr. J. G. Rutherglen and Mr. J. Fraser for their generous assistance in using the Glasgow University Physics Department high-tension set.

A Proton Magnetic Resonance Study of the Hydration of Deoxyribonucleic Acid

DILUTE solutions of deoxyribonucleic acid have high viscosity, very large increment of dielectric constant and high osmotic pressure. It has been suggested that these properties result from the formation of large hydration shells with a higher degree of lattice order than that prevailing in pure water¹. In order to investigate these phenomena further, we have studied proton magnetic resonances of some deoxyribonucleic acid solutions and gels.

Two high polymeric preparations of sodium deoxyribonucleate (according to the method of Gulland *et al.*²) were investigated in concentrations of 0.06–80 per cent by weight. For comparison, 1.6 per cent solutions of haemocyanin (*Helix pomatia*), soluble starch and egg albumin were also studied. Proton magnetic resonances were observed in a magnetic field of about 7,050 gauss with a resolution of three parts in 10⁷. Resonances were displayed on the screen of an oscilloscope and photographed (Fig. 1), and the areas of the traces of the absorption mode were measured³.

The normalized area measurements (col. 2 in Table 1) are representative of the fraction of the water protons which contributes to the signal within a line width of about 15 milligauss. The remaining fraction (col. 3) of the protons has a resonance line that is so broad that it does not contribute to the area measured. (The more concentrated solutions of deoxyribonucleic acid gave resonances the visible line width of which, while noticeably greater than that of pure water, was still less than 15 milligauss.) The broadening of the line may be due to several causes; the most likely in this case are increased order of the water lattice and exchange of protons or water molecules between ordered and disordered phases of the water.

For haemocyanin, starch and egg albumin, the resonance lines were almost identical with the lines for pure water, and no broadening or decrease in

Table 1

Concentration (weight, per cent)	Area per gm water in sample (arbitrary unit). Accuracy, ± 0.06	Fraction decrease of area*	Fraction decrease per conc. unit nucleic acid
Water	1.00	0	
0.06 per cent sodium deoxyribonucleate	0.94	0.06	1.0
0.6 per cent sodium deoxyribonucleate	0.83	0.17	0.23
1.6 per cent sodium deoxyribonucleate	0.66	0.31	0.19
80 per cent sodium deoxyribonucleate	0.15	0.85	0.014
0.06 per cent sodium deoxyribonucleate in 0.016 N NaCl	1.00	0	
1.6 per cent sodium deoxyribonucleate in 0.04 N NaCl	0.84	0.16	
1.6 per cent starch	0.99	0	
1.6 per cent haemocyanin	1.0(5)	0	
1.6 per cent egg albumin	1.0(4)	0	

* Figure represents the fraction of the protons the resonance of which is very broad in comparison with 15 milligauss.

area could be detected. This is to be expected since the degree of hydration of these substances is known to be low.

From the results for deoxyribonucleic acid, we conclude that in the hydration shells of the macromolecules there are some water molecules that have a higher degree of lattice order than that prevailing in pure water. The lattice order in the hydration shells is such that the resonances are broader than 15 milligauss. The observed line-width of pure water was 3 milligauss as determined by magnetic field inhomogeneities.

Since we do not know the amount of exchange broadening, if any, it is not possible to specify the exact size of the hydration shells from our present results. It is only possible to make the following quantitative statements. First, not less than the fraction indicated in col. 2 exists in a phase of sufficient disorder such that the lines are sharp compared to a solid phase such as ice. Secondly, the exchange, if any, between ordered and disordered phases must take more than 0.05 sec.

In principle, line-broadening could arise from a proton exchange between the water and the protons of the macromolecules. However, this effect cannot cause the main decrease in area, since there are not enough macromolecular protons present in the dilute solutions to make possible such a process. Furthermore, col. 4 indicates that an increase in concentration of nucleic acid does not result in a proportionate decrease in area.

On the addition of electrolytes to the nucleic acid solutions, considerable amounts of water previously bound are released to the normal water state, as shown by the larger values for normalized area shown in the table. This agrees well with the results obtained

from dielectric, viscosity and osmotic pressure studies, which indicate that the ordering action of the macromolecules on the water lattice is much reduced in the presence of small amounts of electrolytes. This decrease in hydration is attributed to a contraction of the macromolecules leading to an impairment of the structural fit between the macromolecular surface and the regular

Oscillographic traces for (a) pure water, (b) 1.6 per cent sodium deoxyribonucleate, and (c) 1.6 per cent sodium deoxyribonucleate in 0.04 N sodium chloride

four-co-ordinated water lattice¹. The proton magnetic resonance data support these ideas.

The dielectric method for studying water structure changes induced by macromolecules is more sensitive than the proton magnetic resonance technique. However, dielectric studies cannot be applied to solutions of high conductivity, whereas the proton magnetic resonance method is undisturbed by the presence of moderate amounts of electrolytes. This makes it possible to use the latter method for studies *in vivo*.

We wish to express our gratitude to Prof. Felix Bloch for helpful discussions, and to Dr. L. G. Allgen, Karolinska Institutet, Stockholm, for supplying one of the nucleic acid preparations.

Synthesis of L-Amino-succinimide

In an attempt to account for the differences in the chemical and physiological properties of asparagine and glutamine, Steward and Thompson¹ have suggested that the structure of asparagine is best described by a tautomeric system the major component of which is the monohydrate of amino-succinimide, while glutamine is best represented by the conventional straight-chain formulation. This theory has been questioned by Leach and Lindley², by Katz, Pasternak and Corey³, and by others. Steward and Thompson⁴ pointed out that the synthesis of amino-succinimide and a comparison of its properties in aqueous solution with a solution of asparagine would provide unequivocal evidence either for or against their hypothesis. We wish to report the synthesis of L-amino-succinimide.

In connexion with another investigation, we observed that the attempted saponification, under mild conditions, of carbobenzoxy-L-asparagine methyl ester⁵ does not yield carbobenzoxy-L-asparagine. Instead the major product is a much weaker acid which we identified as carbobenzoxy-L-amino-succinimide, m.p. 79–81°, $pK_a = 9.1$ in aqueous methanol, $[\alpha]_D^{25} = +43^\circ$ (c. 1, 95 per cent ethanol); (calc. for $C_{12}H_{13}N_2O_4$: C, 58.05; H, 4.87; N, 11.29; amide-N, 5.65; found: C, 57.29; H, 5.17; N, 11.25; amide-N, 5.50 per cent). Carbobenzoxy-L-amino-succinimide is also obtained from carbobenzoxy-L-isosparagine methyl ester. Reaction of the imide with aqueous ammonia yields carbobenzoxy-aspartic acid diamide. Prolonged treatment of the imide with alkali at room temperature, followed by hydrogenolysis to remove the carbobenzoxy group, results in the formation of a mixture of asparagine and isosparagine.

Hydrogenolysis of carbobenzoxy-L-amino-succinimide yields L-amino-succinimide, m.p. approximately 144° (decomp.), $[\alpha]_D^{25} = +77^\circ$ (c. 1, methanol); (calc. for $C_4H_7N_2O_2$: C, 42.10; H, 5.80; N, 24.6; neut. equiv. 114; found: C, 42.84; H, 5.28; N, 24.85 per cent; neut. equiv. 118 (titrated with

acid)). Although L-amino-succinimide appears to be quite stable in the crystalline form, the compound is almost completely destroyed when a 1 per cent solution in phosphate buffer of pH 7.0 is heated for fourteen hours at 37°. Electrometric titration of an aqueous solution of L-amino-succinimide shows the presence of a weakly acidic group with $pK_a = 9.0$, the imide-group, and a weakly basic group with $pK_b = 5.9$, the amino-group. A mixture of L-asparagine and L-amino-succinimide can be separated readily by chromatography either with *n*-butanol-acetic acid-water (4:1:5) or with phenol saturated with water. It is thus clear that the properties of aqueous solutions of L-amino-succinimide and L-asparagine are not similar.

Details of these investigations are being published elsewhere⁶.

ERNST SONDHEIMER
ROBERT W. HOLLEY

New York State Agricultural Experiment Station,
Cornell University,
Geneva, N.Y. Feb. 11.

¹ Steward, F. O., and Thompson, J. F., *Nature*, **169**, 739 (1952).

⁵ Bergmann, M., and Zervas, L., *Ber.*, **68**, 1193 (1935).

⁶ Sondheimer, E., and Holley, R. W., *J. Amer. Chem. Soc.* (in the press).

In our earlier consideration of the relationships of asparagine and glutamine, substances which are of great physiological importance, we directed attention to the interest which would be aroused by an unequivocal synthesis of amino-succinimide and whether "it proved to be, when hydrated, identical or different from asparagine"^{1,2}.

Through the courtesy of Drs. Sondheimer and Holley, we have seen their paper³ and communication (above) on L-amino-succinimide in advance of their publication. They are to be congratulated on what appears to be an elegant piece of synthetic work leading to derivatives of L-amino-succinimide and to the pure substance, the properties of which are now described for the first time.

It is of great interest to us that the substance amino-succinimide: (a) is stable in its crystalline anhydrous form; (b) can exist in aqueous solution and show by its titration curve the weakly acidic imide group and a weakly basic amino-group; (c) is distinguishable from L-asparagine by its position on chromatograms, though, like that substance, it reacts brown with ninhydrin on paper; (d) is readily convertible, even by warming to 37° at pH 7.0, to a mixture of asparagine and isosparagine.

It is also of interest that in two ways, referred to by Sondheimer and Holley, there is a ready interconvertibility of the straight-chain form as it is supposed to occur in asparagine and the ring form as it occurs in amino-succinimide. This is shown by: (a) the hydrolysis of the methyl ester of carbobenzoxy asparagine yielding only carbobenzoxyamino-succinimide; (b) the combination of amino-succinimide with water to give asparagine and isosparagine.

It is granted that the evidence of Sondheimer and Holley now is that asparagine and amino-succinimide can be distinguished. The important part of their evidence, in our view, is that which describes the properties of amino-succinimide in the free state and in solution. Apparently, amino-succinimide can exist unhydrated and distinguishable from asparagine, and when it com-

binas with water, which it does very readily at 37° or above, it gives not asparagine only but both asparagine and isoasparagine. While we are grateful to Drs. Sondheimer and Holley for furnishing evidence of the kind which we ourselves would have been glad to obtain, there still remain some features of the asparagine-glutamine problem that require explanation.

Asparagine and glutamine behave differently toward ninhydrin and they also behave differently toward nitrous acid in acetic acid solution. Asparagine reacts toward ninhydrin in two distinct ways. In solution in the cold or on paper at 60° C., it reacts with ninhydrin without being decarboxylated to form a brown compound. This reaction is typical neither of the α -amino-acids nor of glutamine. (In respect to the brown ninhydrin colour, asparagine resembles amino-succinimide more than glutamine.) In hot solutions, however, asparagine, like glutamine, may be made to react with ninhydrin with decarboxylation to give a blue colour and in a manner which is typical of most α -amino-acids. In the reaction with nitrous acid, the amide group of asparagine does not react, whereas that of glutamine does.

These anomalies and interesting physiological differences between glutamine and asparagine still require to be fully explained—even though, from the work of Sondheimer and Holley, one cannot now regard L-asparagine as a simple hydrate of L-amino-succinimide.

Hydrogen Bonding and the Volume of Water

WATER behaves approximately as a normal liquid with respect to its volume at a high temperature and pressure. The expected volume of the liquid at room temperature is obtained by extrapolation, for example, using the formula of Jacobson and Heedman¹. The volume thus deduced corresponds to a state without hydrogen bonding (at 0° C. about 8 per cent denser than ordinary water). Each hydrogen bond formed at a given temperature ($t < 174^\circ$ C.) is now assumed to affect the ideal liquid in the same way, raising the molecular volume to that of ice when two moles of hydrogen bonds are established. (Ice is supposed to exhibit the same thermal expansion above 0° C. as immediately below.)

Introducing the observed volume of water, these assumptions render possible the determination of the molecular fraction of hydrogen bonds, X , as a function of temperature. At 0° C., X is calculated to be 0.44, decreasing to 0.23 at 100° C. When no hydrogen bond is broken, the number being two per molecule, X is one.

Following Finbak², the law of mass action is applied to the formation of hydrogen bonds. The breaking of a bond gives two sites for bond formation. Thus a graph of $2 \ln(1 - X) - \ln X$ against $1/T$ was investigated. An almost straight line was obtained, corresponding approximately to an enthalpy change of 2.6 k.cal./mole water and an entropy change of 8.9 cal./mole.

A hydrogen-bond energy of 1.3 k.cal./mole seems quite low, compared with the current estimates for water. There has been no general agreement, however, on the energy of the hydrogen bond. This is probably due to difficulties in defining and sharing out the different energies. The present investigation indicates that 2.6 k.cal./mole is responsible for the tendency towards tetrahedral configuration in water. This is ascribed to the hydrogen bond. The van der Waals's energy superimposed gives only a very loose orientation effect, though it is probably partly included in most hydrogen-bond energy determinations.

A detailed discussion will appear later elsewhere.

Reduction of Tetrazolium Salt

SOME two hundred papers dealing with the chemistry of triphenyltetrazolium chloride and its use as a redox-indicator have been reviewed by Ried¹ and Smith². In spite of its wide use in biology, up to the present little is known about its reducing mechanism, the influence of experimental conditions on it, on its redox-potential, etc., and therefore the results obtained with it are empirical in character. Investigations of the salt by means of polarography and spectrophotometry carried out in this laboratory revealed some aspects which should be considered when using it as a chemical indicator of reducing power in biological reactions.

Polarographic study has shown that, in media of pH lower than 6, the reduction of triphenyltetrazolium chloride yields chiefly a colourless product:

In more alkaline solutions the reduction product is mainly the red formazan. This behaviour is due to the change of redox-potentials in the reduction of nitrogen atoms 1 and 2, and atoms 2 and 3 respectively (Fig. 1), and explains why reddening can be achieved only in solutions which are not too acid. The redox-

Fig. 1. Redox-potentials of triphenyltetrazolium chloride. Reduction of nitrogen atoms 2 and 3 (curve I) and of atoms 1 and 2 (curve II).

Fig. 2. Reaction-time curves of 10^{-3} M triphenyltetrazolium chloride

Curve I; disappearance of pure triphenyltetrazolium chloride in solution in light, neutral medium.

Curve II, a: formation of formazan, in the presence of 10^{-3} M ascorbic acid, pH 10.8, in light. Curve II, b: the same, in darkness. Curve III, a: formation of formazan in a diluted suspension of yeast (0.1 gm. $\rightarrow$ 10 ml), pH 7.5, in light. Curve III, b: the same, in darkness.

potential of formazan formation, contrary to other redox-indicators, cannot serve as a basis for predicting whether some reducing agent of known redox-potential will produce formazan or not. This is due to the insolubility of the reduced form of triphenyltetrazolium chloride: no redox-equilibrium can be established, and the actual potential of the substance will be therefore much more positive than its normal potential. This shows why triphenyltetrazolium chloride can be reduced by succino-dehydrogenase, which has a much more positive normal redox-potential.

Another important point to be considered is the influence of light on the enzymatic and non-enzymatic reduction of triphenyltetrazolium chloride. Fig. 2 shows that both types of reduction take place only in light; there is no reddening in darkness, except non-enzymatic reduction in strongly alkaline solution. Fig. 3 shows the influence of pH on both types of reduction, indicating clearly the basic difference between the two types of reactions. Fig. 2 shows also that triphenyltetrazolium chloride even in pure solution is converted by light into a 'photo-compound', which cannot be reduced to formazan. (The source

Fig. 3. Influence of pH on the formation of formazan in 10^{-3} M triphenyltetrazolium chloride, solution allowed to stand 2 hr with ascorbic acid (yeast). Details as in Fig. 2

of light in these experiments was the scattered light of the blue sky, of about 2,500 lux.)

Formazan is decomposed photochemically, as shown by Kuhn and co-workers². According to our experiments, this is an autocatalytic reaction, with the 'photo-compound' as catalyst. Hydrogen peroxide is formed as a by-product.

An interesting factor causing complications is further that triphenyltetrazolium chloride is converted into formazan in strongly alkaline medium spontaneously without the action of light or any reducing agent.

These results show clearly that the conditions must be carefully controlled when triphenyltetrazolium chloride is used for quantitative experiments.

Further details of this investigation will be published elsewhere⁴. I am indebted to Arapahoe Chemicals, Inc., Farbenfabriken Bayer and Lewis Laboratories, Inc., for supplying the triphenyltetrazolium chloride.

Leucofuchsin in Algal Cytology

Astbury and Sana, in an article in *Nature*¹, state that there is some correspondence between the X-ray diagram of *Polytoma* flagella and that of certain polysaccharides; but no chemical confirmation of the presence of this type of compound could be found.

The diversity in structure of various algal flagella cautions against generalization. While the electron-micrograph given by Astbury and Sana represents *Euglena*, the X-ray diagram refers to *Polytoma*. These organisms are not closely related, if at all, and have different flagellar structures. In *Euglena*, the main stem of the flagella is covered with appendages which, in their dimensions and physical properties, recall bacterial flagella, although their function and behaviour are unknown.

In *Polytoma*, the delicate distal part of the flagella has approximately the same width as the appendages of the Eugleninean flagellum though it is stiffer, while the basal part is almost as thick as the flagellum of *Euglena*. There are still more differences in flagellar structure between the phyla of flagellates, which have to be kept in mind when investigating the physical and chemical nature of algal flagella.

By accident I came across a reaction which might be of help in such studies. In an attempt to learn something about the composition of paramylon, the peculiar reserve substance of the Euglenineae, which is chemically and physically similar to starch, the leucofuchsin technique, as used for demonstrating polysaccharides in histology², was employed; in this method, after oxidation with periodic acid, the cells are treated with Schiff's reagent (leucofuchsin). The result is that, unlike starch, paramylon is not stained.

All the flagella tested, comprising those of *Euglena*, *Eutreptia*, *Phacus*, *Cyclidiopsis*, *Polytoma*, *Chlamydomonas*, *Gonium*, *Ochromonas* and *Cryptomonas*, gave a positive reaction and became red in every instance,

those of the first four most distinctly, probably because they belong to the Euglenineae, which have wider flagella than the rest. Pre-treatment with saliva and washing with fat-solvents made no difference.

This positive reaction supports the view that there is, apart from proteins, also a polysaccharide component in all these flagella. The polysaccharide may have something to do with the marked elasticity of algal flagella and their defined way of beating, characteristics which are lacking in bacterial flagella and in the appendages of the Eugleninean flagellum, to judge by their shapes in electron-micrographs. The flagella of bacteria do not contain polysaccharides, so far as we know. The cilia of *Paramecium caudatum*, which are much shorter than flagella, do not seem to need elastic stiffening and give no leucofuchsin reaction.

A positive Schiff's reaction, however, was obtained after oxidation with periodic acid in the chlorophyll-containing chromatophores of all the organisms tested: Volvocales, Cryptophyceae, Euglenineae, Peridineae and Chlorophyceae, while without previous periodic-acid treatment no staining took place.

Apart from the Feulgen reaction, Schiff's reagent has previously been used for staining cell-walls of Algae. Prät² found that those of Heterococcales became purple-red with this reagent, in contrast to the cell-walls of Chlorophyceae. I can confirm his result.

After treatment with periodic acid, a positive result with Schiff's reagent is given by cell-walls of Cyanophyceae, *Spirogyra* and some Volvocales. A few Chlorophyceae tested were negative.

It may be mentioned that the leucofuchsin solution should be nearly colourless, or only pale yellow, but must not show the faintest tinge of pink, as traces of the unreduced fuchsin have a strong staining power.

I thank Dr. H. B. Fell for laboratory accommodation and the New York Zoological Society for a grant.

Identity of Auxin in Normal Urine

THE aim of this work was to obtain auxin *a*, first isolated by Kogl, Haagen-Smit and Erxleben¹ from human urine in 1933. In their isolation procedure, these workers extracted a urine concentrate at an acid pH with ether. The ether extract in turn was partitioned into a neutral and an acid fraction with sodium bicarbonate. The auxin was present in the acid fraction and was subjected, in the final stages of the isolation procedure, to refluxing with methanol

Fig. 1. Above: paper chromatograms of 3-indoleacetic acid and of its methyl ester compared with fractions 15 and 17 from urine. Below: biological activity of ten equal segments of the paper strips (R_f 0-0.1, 0.1-0.2, etc.) by the split *Avena* coleoptile test

containing 1.5 per cent hydrochloric acid. This step was followed by high-vacuum distillation, yielding a crystalline material with high auxin activity which they called auxin *a*.

In the present work, the procedure of Kogl *et al.* has been followed throughout. The auxin activity of the fractions was determined not by the *Avena* curvature test but by the split coleoptile test of Thumann and Schneider², which will detect 0.1 mgm./litre of 3-indoleacetic acid. Two batches of 40 litres of urine were processed and from them, after treatment with methanolic hydrochloric acid and high-vacuum distillation, a pale yellow oil was obtained having an activity about ten times that of indoleacetic acid as estimated by the split *Avena* coleoptile test.

The high-vacuum distillate (fraction 17) and its precursor before esterification with methanolic hydrochloric acid (fraction 15) were both studied by paper chromatography using the solvent system isopropyl alcohol-water-ammonia, 80-15-5. Some of the strips were sprayed with ferric chloride in perchloric acid³, others were cut into ten equal segments, each segment being placed in a Petri dish with three split *Avena* coleoptiles. The location of the coloured spots on these strips and the distribution of biological activity is shown in Fig. 1.

Fraction 15 gave a pink spot identical in colour with that given by 3-indoleacetic acid of R_f value 0.48 (3-indoleacetic acid had R_f 0.48). Fraction 17 gave a purple spot (R_f 0.77) identical in colour with that given by the methyl ester of 3-indoleacetic acid (R_f 0.78), which was prepared both by refluxing 3-indoleacetic acid with methanolic hydrochloric acid and by treating a methanolic solution of 3-indoleacetic acid with diazomethane. From fraction 17 a crystalline picrate was obtained identical with an authentic sample of the picrate of the methyl ester of 3-indoleacetic acid.

As can be seen from Fig. 1, the auxin activity on the paper strips (shown by curvature of the split

halves of the *Avena* coleoptile) coincided exactly with the coloured spots. No other region on the strips had auxin activity and none of the other fractions was active. These findings are in agreement with those of Bennet-Clark *et al.*³, who were unable to detect any auxin other than 3-indoleacetic acid in paper chromatograms of an ether extract of urine.

When the isolation procedure of Kögl *et al.*⁴ was applied to a solution of 3-indoleacetic acid, it resulted in the isolation of the methyl ester of this substance. There appears to be no step in this isolation scheme which would eliminate 3-indoleacetic acid or separate it from auxin *a*. In their paper on the isolation of 'hetero-auxin', Kögl *et al.*⁴ state that it remains a "companion of auxin *a* for a long time" but that "the last traces of heteroauxin are destroyed by refluxing with methanol containing 1.5% HCl". In our work, however, no such destruction was observed, provided dry methanol and dry hydrogen chloride were employed.

These results lead to the following conclusions:

(1) Neither of the two 40-litre samples of urine processed contained any auxin except indoleacetic acid.

(2) Treatment of the active fraction with methanolic hydrochloric acid does not destroy the 'hetero-auxin' as suggested by Kögl *et al.*⁴ but converts it to the methyl ester. The auxin activity of this ester as estimated by the split *Avena* coleoptile test and by the split pea internode test was greater than that of 3-indoleacetic acid. Kögl and Kostermann⁵ found the methyl ester less active than the free acid when tested by the *Avena* curvature test.

Blood-sugar in Foetal and Neonatal Mammals

It is well known that glucose is not found in equal concentration in the water phase of the red cells and plasma from some species of adult mammals. Nevertheless, it is conventional and convenient to cite values for the glucose concentration in the whole blood, and in studies confined to man this practice is generally satisfactory. In comparative physiology there is less justification for this convention, because it is the plasma glucose concentration which has a more direct influence on the tissue-fluid glucose concentration and sugar-regulating mechanisms. The difference between whole-blood and plasma glucose concentration is frequently considerable, for when the red cell is seemingly devoid of glucose, the plasma glucose concentration is, on the average, about 1.5 times the blood glucose concentration.

The importance of estimating plasma glucose became obvious in this laboratory during a study of the glucose concentration gradient across the placenta of the guinea pig. The blood glucose con-

Maternal circulation		Foetal circulation

88	116	87	97
80	110	70	86
Mean 86	116	84	93

centration was sometimes virtually the same in the foetal and maternal circulations but, on estimating plasma glucose, a considerable concentration gradient existed towards the foetus as shown in the accompanying table.

Previously, Hitchcock¹ had reported peculiarities in the corpuscular/plasma distribution of glucose in the young lamb. His findings suggested that this ratio declined rapidly after birth. In addition, Andreen, Svedberg² had observed a high distribution-ratio for glucose in blood from young calves and a baby pig.

In view of the implications above, this phenomenon has been examined in a large number of animals of several species (horse, pig, ox, sheep, goat, guinea pig and rabbit).

Fresh blood was collected over dried heparin at about 2° C. and, after sampling, the remaining blood was centrifuged in cups packed with ice until sufficient plasma was exposed. Generally, all deproteinization (using barium hydroxide and zinc sulphate) was complete within about twenty minutes of obtaining the blood. Glycolysis has been shown to be negligible during the whole procedure. Corpuscular glucose was derived from a knowledge of blood and plasma glucose and the packed cell volume. It is assumed that this technique, which examines the red cell in its natural medium, does in fact measure the *in vivo* concentration of glucose. The methods for estimating sugar have been described in a previous publication³.

The following general observations have been made.

1. The distribution of glucose usually conforms to one of two conditions: (a) an approximately equal concentration of glucose in the water phase of the red cell and the plasma (assuming that the water contents are similar to those in man); (b) a low or zero concentration of glucose within the cell. These two states may represent the conditions of free permeability and impermeability; but, pending further investigations along these lines, they will be referred to here as 'state *a*' and 'state *b*'.

2. In most species examined, the foetal and immediately post-natal corpuscles are in state *a* and, during the neonatal period, they change gradually to state *b*. It is possible that there are only two types of corpuscle and that the first is slowly replaced by the second.

3. The period of life during which this red-cell change occurs can vary with species: the corpuscles in the new-born pig being in state *a*, while those of the foal at birth are already in state *b*. As the change has always been observed to be from *a* to *b*, it is assumed that *a* is more immature and that a physiological change in the reverse direction would never occur. The persistence of the *a* corpuscle throughout life in man may be a reflexion of the mode of evolution of this species.

4. The consistently higher concentration of glucose within the cell compared with that in the plasma, as described by Hitchcock for the foetal lamb, has not been seen in this work for any species at any age.

5. A further complication may result in animals where more than one sugar is present in the blood³, for preliminary results suggest that the corpuscular/plasma sugar distribution may be different for glucose and fructose.

From these results, it is clear that, in foetal and neonatal physiology, the term 'blood-sugar' should be used only in a strictly literal sense. Figures derived from blood-sugar estimations cannot be legitimately compared, either for different species or for different ages of one species, without allowing for the particular characteristics of the red cell in each sample.

I am indebted to Dr. R. Scarisbrick, who not only directed my attention to this problem, but suggested that it should be developed in this way.

Resistance to the Maize Rust, *Puccinia polysora*

DURING 1953 we have studied resistance in maize to the form of the rust fungus, *Puccinia polysora* Underw., that recently appeared in East Africa¹. Our results augment the information given by Stanton and Cammack².

In our glasshouses at Muguga, Kenya, inoculation of young maize seedlings with fresh uredospores regularly caused infection, once technique was perfected. In a susceptible maize, uredosori were strongly developed about fourteen days after inoculation (Fig. 1). There was some variation between plants in the size and frequency of the sori and in the extent of the chlorosis surrounding them. Some plants, however, gave a distinct reaction, readily distinguished from any variant of the preceding reaction, the inoculated leaves showing only discrete, nearly circular necrotic areas, in which no sori developed or minute sori with limited spore-production (Fig. 2). This resistant reaction resembles the hypersensitive reaction well known with the rusts of wheat; it conforms with the description of Stanton and Cammack's "Stage 1"². A few plants, selected as seedlings, were grown to maturity in a glasshouse and reinoculated at intervals; their reaction at later stages of growth resembled that shown by them as seedlings.

Fig. 1. *Puccinia polysora*. Susceptible reaction in maize leaf. Large spreading sori. ($\times 175$)

Fig. 2. *Puccinia polysora*. Resistant reaction in maize leaf. Necrotic areas with some small sori. ($\times 175$)

Table 1 SELFED PROGENIES

Expectation on 3:1 ratio			130	43

None of our material has given evidence of immunity from invasion by the fungus.

The resistant reaction was not found in any of forty-two maize varieties and lines received from sources in Africa. It was found in a few plants among collections originating in Mexico (received through Dr. W. Stanton) and in Colombia (Dr. L. M. Roberts, Agricultural Experiment Station, Medellin). Of twenty-five varieties and lines from these sources, fifteen gave only the susceptible reaction and the resistant plants were confined to the remaining ten.

Individual plants showing the resistant reaction were grown to maturity and selfed or crossed with susceptibles. Twelve progenies raised from selfed seed were tested. Of these, one gave forty-five plants all resistant in seven separate tests. The remaining eleven segregated into resistant and susceptibles as shown in Table 1.

Thirteen resistant plants were crossed with susceptibles; one gave twenty-eight plants all resistant (four tests) and the remainder segregated (Table 2).

The evidence indicates the presence of one major dominant gene for resistance. Differences in the responses that have been classed together as indicating susceptibility in the above progenies, and also in some progenies of North American origin, suggest the presence of at least one other gene with an effect

Seedling Resistance and Mature-Plant Susceptibility of Wheat to *Puccinia graminis* found in Kenya

BREEDING and selection of wheat in Kenya for resistance to black stem rust has been based on seedling resistance tests coupled with identity tests of rust forms from the field and the breeding cages. Owing to lack of facilities, mature-plant tests have not been undertaken.

Though seedling and mature-plant resistance has been demonstrated to be independent¹, it has been found in Kenya that, by selecting resistant seedling lines, mature-plant resistance until recently has always been obtained. Such was the success of the plant breeders that the value of Kenya wheats has been recognized in various parts of the world, and they have been used as parents in breeding programmes, for example, in Australia, India, Egypt, the United States and Canada. Several seedling-susceptible but mature-plant resistant lines may well have been discarded in this process, for it is known that some varieties develop a mature-plant resistance from about the fifth leaf stage². This character was used by E. S. McFadden when he produced Hope and H.44.24 by crossing Yaroslav Emmer and Marquis³.

This seedling resistance-mature-plant resistance has, however, not held throughout. Seedling resistance-mature-plant susceptibility has been found in the following Kenya lines: 184 and 318 and in D.C. x Ceres R.46. These wheats were seedling resistant to certain rust forms by which they were attacked in the field. Their seedling resistance to other rust forms has apparently been maintained. All selections of these lines do not exhibit this behaviour, but remain constant in their resistance or susceptibility.

It has recently been shown in the United States⁴ that lines involving Montana and some other parents behave in a like manner.

I wish to thank the Honorable Director of Agriculture, Kenya Colony, for permission to publish this preliminary communication.

Parasit Canker: Selection of Resistant Stocks of Parsnip

THE account by A. P. Jones¹ in *Nature* on *Streptomyces scabies* (Thaxter) Waksman and Henrici as the probable cause of parsnip canker is a welcome addition to the literature on a problem which has defied solution by various investigators during the past forty years. Previous to the above work, a survey of the problem was made by us during the period 1946-49 at the request of the Horticultural Group of the Agricultural Improvement Council and the results were embodied in the report AIC/HG/20, a summary of which was published in *Agriculture*². That report claimed to be no more than a fresh examination of the problem; but, although the exact nature of the causal organism was not discovered, a good deal of information was obtained. During the investigation it was clear that although no commercial variety or strain of parsnip was worthy of being called resistant to canker, there were always individual roots which in badly affected fields remained free from the trouble. This point has been noted by previous workers³.

Consequently, while the examination was proceeding, a look-out was kept for roots which remained clean in areas where canker was abundant. Such roots were intended to form a foundation for the selection and breeding of canker-resistant stocks possessing characters suitable for commercial crop production such as those possessed, for example, by the variety called Evesham. This variety is yellow-fleshed, broad in the shoulder and short in the root (that is, peg-top in shape) and is much valued on heavy soils because it lifts easily where longer varieties break off. It is, however, rather prone to canker.

The first roots were selected at the end of the very bad canker year of 1948, after which, in the spring of 1949, it was difficult to find parsnip roots free from canker. With the assistance of National Agricultural Advisory Service advisers in different parts of the country specimens were gathered and forwarded to Wisley, and from them ten clean roots of suitable types were chosen. These were planted at Wisley for seed production. Seven survived and were seeded under large muslin bags, and the seed was sown in February 1950 in heavy land where canker usually occurs. As the main investigation had shown that canker infection increases after October in any year, it was decided to leave the roots until late spring before lifting for examination.

The seven stocks sown in February 1950 were lifted in March 1951. In no case was canker severe, and two stocks (Nos. 4 and 5) were completely clean and of a good type. From them seven good roots were selected and replanted, protected with muslin, and seed harvested from each in the autumn. This was sown on the same land in February 1952 and the crop was lifted on March 10, 1953, when canker infection in six of the stocks varied from 0 to 11 per cent. The seventh stock, of which the seed had been badly discoloured, gave 34 per cent cankered roots. These roots were very large, their average weight being 50 per cent more than that of roots in the next heaviest stock, and this point may have some connexion with their susceptibility to canker. The fact remains that, in this trial as in previous ones, although canker was present in some stocks, there were others free or practically free from the trouble. The work to date indicates that resistance to canker

¹ Haynes, H. K., Stakman, H. C., and Aamodt, O. S., *Phytopath.*, 18, 371 (1925).

² Craigie, J. H., Dept. of Agric. (Canada) Pub. 606 (1940).

³ Campos, T., Gihler, J. W., and Boriang, N. B., *Phytopath.*, 43, 468 (abt) (1953).

exists in certain stocks from which it may be possible to select or breed varieties combining the resistance with acceptable commercial characters.

During the latter part of the work we have been in touch with the staff of the National Vegetable Research Station, and we are indebted to them for much interest in the parsnip trials. As part of their work will deal with parsnip canker, it was decided to offer them any material in which they were interested and this offer was accepted. Accordingly, at the lifting in March 1953 roots from each of our seven stocks of parsnips were sent to Wellesbourne for seeding there and in the hope that they will be of some value in any further research on canker. This communication is written to explain the origin and history of the stocks from the spring of 1949 onwards.

Factors Influencing the Emergence of *Heterodera rostochiensis* Larvae

MANY investigators have reported a considerable variation in the seasonal rate of hatching of eggs from the cysts of *Heterodera rostochiensis*, in the presence of root diffusate.

Both Fenwick¹ and Lownsbury² have shown that the direct effect of temperature on cysts *in vitro*, in the presence of root diffusate, caused an increase in the amount of hatching with rise in temperature. They found the optimum rate of hatch was between 21° and 25° C., and both reported inhibition of hatching or dormancy at temperatures of 30°-33° C.

Recent investigations in this laboratory indicate, however, that seasonal variations in hatching are not simply the result of a direct correlation between temperature and hatching. It has been shown that the rate and amount of hatching from viable cysts of the same age maintained at 15° C. is profoundly influenced by the maximum temperatures to which the moist cysts have been subjected previously, before the addition of root diffusate. Except for a very brief note in a paper by Calam, Raistrick and Todd³, there appears to be no record of this indirect effect of temperature on moist cysts.

Samples of cysts of the same age were kept in water at temperatures of 15°, 23° and 29° C. for 34 days, and afterwards at 15° C. Two days later root diffusate was added to all samples. Four days afterwards, the cysts which had been pre-heated at 23° C. produced a hatch twenty to thirty times as great as the hatch from the cysts kept at 15° C., while none hatched from the cysts pre-heated at 29° C. All attempts to hatch eelworms from samples of cysts which had been kept at 29° C., by the addition of root diffusate, failed until twenty days after removing to the lower temperature of 15° C. The hatch was then very rapid and somewhat similar to that from cysts pre-heated at 23° C. Small amounts of hatching also occurred after the twentieth day in control batches of cysts pre-heated at 29° C. and to which no root diffusate had been added, in numbers similar to the emergence from cysts kept at 15° C.

These hatching results may explain the unexpected tomato and potato crop failures which occasionally occur at moderate viable cyst population levels, and would seem to explain the absence of winter dormancy reported by Fenwick¹ and the winter dormancy noted by Lownsbury² in the United States, where according to him the mean soil temperature of 6 in. depth averaged 22° C. during the summer.

This work is being continued and these results will be reported more fully elsewhere.

Effect of Oxygen on the Fixation of Nitrogen by *Azotobacter*

RECENT studies on the fixation of molecular nitrogen by both anaerobic¹ and aerobic² heterotrophic nitrogen-fixing bacteria indicate that ammonia is the first stable compound formed. This raises the question whether the necessary hydrogen is derived from water or from the metabolite. The latter source seems the more likely, especially since the union of metabolic hydrogen and molecular nitrogen to form ammonia could yield a considerable amount of free energy. If this were so, members of the anaerobic genus *Clostridium* would be expected to fix nitrogen more efficiently than the aerobic *Azotobacter*, which passes its metabolic hydrogen to oxygen. Results obtained in this laboratory show that *Clostridium* is, in fact, capable of more efficient nitrogen fixation than *Azotobacter*³. Again, if metabolic hydrogen is involved in the reduction of molecular nitrogen then, with a nitrogen-fixing aerobe, oxygen must compete with nitrogen for this hydrogen and so depress fixation. Conflicting results have been reported for the effect of partial pressure of oxygen on nitrogen fixation by *Azotobacter*⁴.

The effect of oxygen upon nitrogen fixation was examined in this laboratory using one strain of *Azotobacter vinelandii* and one of *Azotobacter chroococcum*. Both were slow-growing strains, and were grown in shallow liquid layers to allow ready diffusion of gases into and out of solution. The medium was a 1 per cent sucrose salts solution at pH 7, and contained yeast extract. 10-ml. aliquots were poured into 10-cm. Petri dishes, inoculated and incubated at 28° C. in sealed jars with different partial pressures of oxygen. The atmospheres in the jars were renewed frequently until the cultures were harvested after 21 days. Inoculated controls were acidified, stored and analysed with the cultures by micro-Kjeldahl method. At 4 per cent oxygen, *A. vinelandii* fixed 23.5 mgm. nitrogen, and *A. chroococcum* 21.6 mgm. nitrogen, per gm. sucrose supplied; at 20 per cent oxygen the fixation was 8.1 mgm. and 7.4 mgm. nitrogen respectively. These results showed greatly increased nitrogen-fixing efficiency with decreased partial pressures of oxygen (significant at the 0.1 per cent level).

When considered with the reported inhibition of nitrogen fixation by molecular hydrogen⁵, the inhibition by oxygen suggests that it is dehydrogenase hydrogen which is passed to nitrogen. Thus nitrogen

fixation might well be a form of respiration with nitrogen acting as an alternative to oxygen as a terminal hydrogen acceptor.

The bacteriological and agronomic implications of this theory will be discussed elsewhere, and further observations presented.

My thanks are due to the Rural Credits Development Fund of the Commonwealth Bank of Australia for financial assistance, and to Dr. R. J. Swaby, of the Division of Soils, Commonwealth Scientific and Industrial Research Organization, Waite Institute, Adelaide, for the culture of *Asotobacter vinelandii*.

Second Ecdysis of Infective Nematode Larvae Parasitic in the Horse

THIRD-STAGE infective nematode larvae retain the sheath of the previous stage and, upon ingestion by the host, this is shed to liberate the enclosed individual. Lapege¹ showed that 'Milton' could induce an artificial ecdysis in the third-stage infective nematode larvae of sheep. Glaser and Stoll^{2,3} have reported successful results using a similar 'Labarraque' solution. Lapege⁴ induced ecdysis in a mixture of hydrochloric acid and sodium hydroxide at pH 9-10 and, apart from the time taken (8-10 days), the process seemed normal. Crofton⁵ studied the second ecdysis of *Trichostrongylus retortaeformis* (Zeder) and found that it could be initiated by pepsin and hydrochloric acid at pH 4-5, 60 hr. being required for exsheathment to occur. Stoll⁶ investigated the ecdysis of the first parasitic stage of *Haemonchus contortus* (Rudolphi) and reported that it occurred in hypotonic Ringer or Tyrode solutions, the addition of aqueous liver extract being highly beneficial.

Experiments conducted here with hydrochloric acid and sodium hydroxide both alone and in combination to give pH 8.5 have repeatedly failed to induce ecdysis in the third-stage infective larvae of the following equine nematodes: *Strongylus vulgaris* (Looss), *S. edentatus* (Looss), *Triodontophorus* spp., *Trichonema* spp., *Oesophagodontus robustus* (Giles) and *Trichostrongylus axei* (Cobbold). A temperature of 38° C. was maintained in all the experiments.

Successful ecdysis of the above species has, however, been repeatedly induced by utilizing muslin-filtered duodenal contents from freshly killed horses. The quickest time yet recorded for 100 per cent ecdysis is 1½ hr. in duodenal contents diluted with an equal volume of distilled water—the whole being kept at 38° C. Experiments with varying dilutions of duodenal contents have shown that the rate of ecdysis is directly proportional to the concentration.

Two distinct methods of ecdysis have been seen. The first is by detachment of a cap at the anterior end of the sheath as reported by Lapege⁴ for *Haemonchus contortus*, *Ostertagia circumcincta* (Stadelmann) and *Trichostrongylus* spp. after 8-10 days, and by Crofton⁵ for *Trichostrongylus retortaeformis* after

Third-stage larva of *Trichonema* sp. undergoing ecdysis by means of a split in the oesophageal region. (Photo. by O. Hughes)

60 hr. A similar process occurred in *Strongylus vulgaris*, *S. edentatus* and *Trichostrongylus axei* and was seen in some cases 60 min. after the addition of duodenal contents. The second method, which was observed in *Trichonema* spp., *Triodontophorus* spp. and *Oesophagodontus robustus* to occur equally quickly, does not involve the shedding of a cap. Larvae of these species develop a bulge at the anterior end in the region of the oesophagus, lashing movements enlarge this and eventually it ruptures to produce a split through which the larva escapes. The accompanying figure shows a *Trichonema* sp. larva leaving its sheath by this means.

Further investigations now nearing completion show that normal ecdysis may be induced by boiled duodenal contents, pig or horse bile and sodium taurocholate. No ecdysis occurred in sodium glycocholate or taurine. The complete results of these experiments will be published in the near future.

Reproduction in Notostraca (Crustacea)

In some species of Notostraca, populations occur in which no males are found and these have generally been considered to reproduce by parthenogenesis; the European *Triops* (= *Apus*) *canoniformis* (Bosc.) exhibits a geographical variation in the occurrence of males, which are less common, or absent, in the north of its range, so that the species has been supposed to show parthenogenesis in colder, bisexuality in warmer regions, in the same manner as *Trichoniscus* (Isopoda, Crustacea).¹

The account in the year 1889 by Bernard² of the discovery of testis lobes in the gonads of female *Triops canoniformis* has been overlooked by recent writers; but during systematic work, in which this genus is being investigated cytologically, I have found testis lobes in the gonads of all the specimens which were examined from so-called parthenogenetic races

of *T. cancriformis*. These lobes can readily be seen in sections, smears and whole mounts of the ovotestes.

No living males of *Triops cancriformis* are yet available, and in order to confirm the nature of the lobes in the ovotestis of the hermaphrodites, testes of male *Triops granarius* (Lucas) (syn. *T. numidicus* (Grube)) have been examined for comparison. In each species the spermatocytes in all stages and round, non-flagellate sperms were found to be identical.

It has been possible to obtain evidence from chromosome numbers to show that the sperms produced in the ovotestis are functional. In *Triops cancriformis* both oocyte and spermatocyte nuclei have a haploid number of four chromosomes, while dividing cells of the follicle epithelium show that the diploid number of the species is eight. Precisely similar chromosome numbers occur in the same cells of bisexual *T. granarius*, in which cross-fertilization takes place. The hermaphrodites appear to be self-fertilizing, for pairing does not occur and sperms are present in the oviducts and follicle ducts throughout adult life.

Hermaphrodites are able to lay viable eggs in the absence of males, a fact long known for the so-called parthenogenetic races of *Triops cancriformis*, and it has now been possible to confirm this with *Triops longicaudatus* (Le Conte) from a Californian rice-field population consisting entirely of 'females', which lay viable eggs into their brood-pouches in the absence of males. Their gonads proved to be ovotestes, similar to those of *T. cancriformis*.

In other species bisexuality appears to be invariable, for in examining many samples of *Triops granarius* from Africa and Asia, I have found no instance where a large number of females without males might indicate hermaphroditism. The ovaries of this species were found to contain no testis lobes, a fact correlated with the inability of the females to lay eggs in isolation, and confirmed abundantly with cultures from two South African localities. A single female of *Triops australiensis* (S. and H.) reared in isolation laid no eggs, thus fitting in with the account of Spencer³, who examined ovaries of this species shortly after Bernard's report and found no testis lobes.

The populations of *Triops cancriformis* present an interesting problem; in some parts of the range the species is hermaphrodite, in others males occur sporadically, while bisexuality appears to be normal in North Africa. Brauer⁴ showed that females from a central European population with sporadic occurrence of males were able to produce viable eggs in isolation, but they copulated normally when reared with males. I have not been able to obtain females from such a population to find out what mechanism enables them to produce viable eggs without mating. A female from a bisexual population from Algeria had no testis lobes in the ovaries, and it appears likely that the normally bisexual *T. cancriformis* reproduces in the same manner as *T. granarius*.

Bernard^{5,6} also described an ovotestis in *Lepidurus arcticus* (Pallas) and in *Lepidurus apus* (L.). Specimens which I have examined of the former species from Alaska have, as he described, testis lobes crowded at the posterior end of the gonad, but no further investigation of this genus has yet been possible.

Hermaphroditism appears to be rare in Crustacea⁷, having previously been known only in the Cirripedia, although in some Decapoda and some parasitic Isopoda a sex-change occurs during life.

Systematic and cytological work is being continued on *Triops* and will be described fully elsewhere when it is completed.

Iron Excretion by *Daphnia* during Hæmoglobin Loss

Daphnia contains hæmoglobin in solution in the blood. The concentration of the hæmoglobin is variable and depends upon the quantity of oxygen dissolved in the outside water: the less oxygen, the redder is the blood¹. I have made a histological study of the distribution of iron in the tissues of *Daphnia magna* Straus when gaining or losing hæmoglobin in response to a changed oxygen content of the water, and have found that when hæmoglobin is being lost from the blood, inorganic iron accumulates in the excretory organs.

The paired maxillary glands, or shell glands, of *Daphnia* are the excretory organs. Each consists of a closed internal oolomic end-sac, the sacculle, a long winding tube, the labyrinth, and a terminal loop, the vesicle, opening to the exterior². These shell glands lie in the hæmocoel and so are bathed by circulating blood. The presence of inorganic iron was shown by Bunting's modification³ of the Prussian blue histochemical technique. This does not reveal the iron in hæmoglobin.

Iron was found in the shell glands only at the time when the hæmoglobin concentration in the blood was decreasing, which suggests that the iron is derived from the breakdown of hæmoglobin and that it is being excreted. The distribution of iron within the shell gland supports this view, for iron was found both in the walls and in the lumen of the middle section or labyrinth, but only in the lumen of the distal section or vesicle. No iron was found in the inner portion or sacculle. In the labyrinth walls the iron stains as blue granules, but in the lumen it stains as a diffuse blue coloration. It is thus apparent that iron is excreted from the walls into the lumen of the labyrinth and thence passes through the vesicle lumen out of the body.

At the same time as iron appears in the shell glands of *Daphnia* which is losing hæmoglobin, it is found in the walls of the paired anterior gut cæca and in the cells of the fat body. One cannot be certain that the iron in the gut cæca is being excreted, since, unlike the shell glands, the cæca also have iron when the blood is gaining hæmoglobin. But more iron is present in the cæca of animals when losing hæmoglobin than at other times, which points to excretion. In the fat body, too, there is most iron when *Daphnia* is losing hæmoglobin, and this suggests that here is a site of hæmoglobin breakdown, with the liberation of iron to be excreted by the shell glands and perhaps by the gut cæca.

The expulsion from the body of iron derived from hæmoglobin breakdown is in direct contrast to the state of affairs in mammals, where the iron from the

continuous destruction of red blood cells is conserved and used again for further haemoglobin synthesis. In some mammals the iron derived from haemoglobin breakdown is temporarily stored as ferritin⁴, an iron-protein complex found in liver, spleen and bone marrow. I have been unable to obtain crystals of ferritin from *Daphnia* with the aid of cadmium sulphate, but it must be remembered that no ferritin has been found in oxen, sheep or deer.

Another striking difference between *Daphnia* and vertebrate animals is that in the latter, which continuously break down the haemoglobin of old red blood corpuscles, the haem portion of haemoglobin, after losing its iron, is excreted as bile pigment, whereas in *Daphnia* no bile pigment has been detected, either in extracts of large numbers of individuals⁵ or histologically. For the latter purpose I have used the method of Stein⁶. Since not only has no bile pigment been found in *Daphnia* losing haemoglobin, but also no porphyrin either⁷, it appears that the haem is broken down beyond the bile pigment or porphyrin stage to simpler colourless compounds.

The work reported here will be described in full elsewhere.

'Mixed Layer' Minerals from the Ordovician Bentonite Beds at Kinnekulle, Sweden

In the course of an investigation of the bentonite beds in the Ordovician strata at Kinnekulle, Sweden, it became evident that the main part of these beds was composed of clay minerals belonging to the type of 'mixed layer' minerals that have random interstratification of illite and montmorillonite layers. The bentonite beds have been described in a paper by Waern *et al.*¹ by Thorslund, who also collected the materials used in this investigation partly from the two upper thin beds with a thickness of about 1 ft. each, and partly from the lower bentonite bed, which has a thickness of as much as 6 ft.

From chemical analyses, X-ray data, determinations of cation exchange capacities as well as from differential thermal analyses, and also from studies with the electron microscope, two different types of 'mixed layer' minerals have been distinguished. For one type, which is found mainly in the upper thin beds, the relation between illite and montmorillonite was found to be about 3:2. The K₂O content here was about 5 per cent. The other type constitutes the main part of the thick bed and has a much lower relation of illite to montmorillonite (about 1:4). The K₂O content in this case was about 2.5 per cent.

In Table 1 some data are collected for the two different types of 'mixed layer' minerals, and in the accompanying figure are microphotometer curves of some X-ray photographs of preparations, with layers oriented parallel to the basal planes. In this figure curves A, B and C are from pure minerals given here as a comparison, and curves D and E are

Table 1

	Type I Illite/montm. 1:4	Type II Illite/montm. 3:2
K ₂ O content	2.5 per cent	5 per cent
Cation exchange capacity	65 m.eqv./100 gm.	45 m.eqv./100 gm.
Low-order basal reflections of non-oriented preparations	at 13-14 kX. with glycerol { wet 17.8 kX. at 9.3 kX.	at 11.5 kX. { wet 18.9 kX. at 9.6 kX.
Endothermal reaction temp. from D.T.A.	570°-590° C. 880° C.	600°-625° C. 900°-920° C.
Dehydration temp.	120°-180° C. 425°-500° C.	120°-180° C. 450°-550° C.

from the material found at Kinnekulle. Actually, in curve D the double peaks are not so well resolved as could be expected from the photographic film, where the reflexions appear as two separate lines, although somewhat broad. From the curves we can see that the basal reflexions of the 'mixed layer' minerals are shifted in relation to those of montmorillonite and of illite, and that they can no longer be given rational indices that refer to cells of moderate size. This will also be seen from Table 2, where are listed intensities and spacings obtained from those preparations which gave curves D and E in the figure. The diagrams for random interstratification of layer minerals, given by Brown and MacEwan², have been used here to compute the ratio of illite layers to montmorillonite layers, and the values found from their curves are in agreement with those found in this investigation by other methods.

The material was very difficult to disperse in the media commonly used, and even after repeated

Microphotometer curves of X-ray reflections from glycerol-treated specimens, oriented parallel to the basal planes. A, sodium-montmorillonite; B, thin sheet of muscovite; C, illite, Torshult, Sweden; D, mixed layer mineral from Ordovician bentonites, Kinnekulle, Sweden, type II; E, mixed layer mineral from Ordovician bentonites, Kinnekulle, Sweden, type I.

dispersions the sedimentary analyses showed all fractions to contain aggregates of the same type of clay minerals as found in the finest fractions. The material from the thick bed always showed a slight content of kaolinite (see figure, curve B), which was never found in the thin beds. The quartz content was very high in the thick bed and the fraction with particle size less than 2μ also contained some quartz. This mineral was also found in the thin beds, but in a much smaller amount.

The fact that only two distinct types of interstratification of montmorillonite and illite are found in the very abundant material from the bentonite beds at Kinnekulle, and not a complete series of transitions between the end-members, makes it appear probable that certain proportions are more stable than others. No doubt there are variations around the value of highest stability as the reflexions from the bentonite material are always broadened and somewhat diffused, as can be seen from the photometer curves. The proportion of highest stability seems to be connected with a repetition of five layers. In the material from Kinnekulle the ratios 1:4 and 3:2 were found, and earlier a mixed layer mineral of the same type was described by Weaver and Bates⁴, who found the ratio of illite layers to montmorillonite layers to be 4:1.

The material from Kinnekulle has also been compared with bravaissite, which was found by Bradley⁵ to consist of layers of montmorillonite and illite in random interstratification, and type II with the illite/montmorillonite ratio of 3:2 seems to be very nearly related to this mineral.

The following structure formulae are characteristic of each type:

M^+ denotes an exchangeable ion and is chiefly calcium or magnesium in the relation 4:1.

Failure to Publish Scientific Results

PROF. P. A. BUXTON's letter in *Nature* of February 27, p. 410, complaining that the results of the aerial spraying experiments carried out in East Africa have not been made available is misleading and unfair to the workers concerned. Such experiments take nearly three years to complete because, although the air spraying may only occupy a matter of a few weeks, the assessment of the tsetse fly population before treatment, and more particularly after treatment, occupies a considerable time. Nine scientific papers have, however, been written up which deal fully with the work which has been carried out over the past six years. Four of these have already been published in addition to a communication in *Nature*¹⁻⁴, and the remaining five will appear during the present year.

In addition to the papers referred to above, members of the Colonial Insecticides Research Units have published ten scientific papers on other aspects of insecticide work during the past six years, and further papers are following. It is therefore a little unkind of Prof. Buxton to imply that these officers have omitted to write proper papers and have contented themselves with 'one-sided' progress reports. He appears to forget that the primary purpose of spending public money on Colonial research is a practical one, and that unless staff is unlimited the time occupied in the meticulous preparation required for a paper published in a scientific journal means delay in pressing on with the exploitation of preliminary results which can usefully be communicated to all the people most concerned with them by interim cyclostyled reports.

These interim reports have a wide circulation in the 'open' section of *Insecticide Abstracts*. There can be few people actively engaged in research on aerial insecticide treatment of insects who are not fully in touch with the progress of the work being carried out by the Colonial Insecticides Research Units, and none need be so ignorant of it that they are driven to use "other people's work". Although one endeavours to give the fullest references when writing up original work, it is not impossible, when one knows of the existence of work, to refer to it as 'in the press' or 'private communication', whichever is appropriate.

It would be difficult to give accurate figures for the cost of the air-spraying experiments, but it is common knowledge that the work with aircraft is costly. That it has been worth while is shown from the recent work⁵ at Maruzi, Uganda, where, in a sixteen square mile area of bush, a kill of more than 99.95 per cent of tsetse fly has been achieved by spraying from aircraft at a cost of approximately £1,000 per square mile.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Monday, April 26

ROYAL SOCIETY OF EDINBURGH (at 24 George Street, Edinburgh), at 4.30 p.m.—Lectures under the Terms of the Robert Cormack Bequest. Mr. A. B. Roy: "The Occurrence of Commensurabilities in the Mean Motions of Planets and Satellites"; Dr. M. J. Smyth: "Photoelectric Investigations of Solar Corpuscular Radiation"; Dr. J. Omer, Mr. James Ring and Dr. W. L. Wilcock: "Dielectric Interference Filters and their Recent Applications in Astronomical Photography"; Mr. M. W. Orendan: "Photometric Effects of Gaseous Envelopes in Belping Binaries".

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE, PHILOSOPHY OF SCIENCE GROUP (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. W. S. Stiles: "Problems of Colour Vision".

INSTITUTION OF ELECTRICAL ENGINEERS, RADIO SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. W. Lawrence: Informal Lecture on "The Experimental Synthesis of Speech".

INSTITUTE OF METALS (at the Royal Institution, Albemarle Street, London, W.1), at 7 p.m.—Prof. L. F. Bates, F.R.S.: "The Domain Structure of Ferromagnetic Metals" (Annual May Lecture).

Monday, April 26—Saturday, May 1

INSTITUTE OF METALS (Joint meeting with the Société Française de Métallurgie, at Church House, Great Smith Street, London, S.W.1)—Spring Meeting.

Thursday, April 29

Informal Discussion on "Recovery and Recrystallization".

Tuesday, April 27

SOCIETY FOR ENDOCRINOLOGY (in the Barnes Hall, Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 5.15 p.m.—Dr. Gregory Pincus: "Pathways of Steroid Synthesis in the Animal Organism".

SOCIETY OF INSTRUMENT TECHNOLOGY (at Mason House, 26 Portland Place, London, W.1), at 6.30 p.m.—Mr. S. L. Anderson: "Instruments for Testing and Control in the Textile Industry".

ROYAL AERONAUTICAL SOCIETY (in the Library, 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. G. H. Lee: "Aerodynamic and Aeroelastic Characteristics of the Crescent Wing".

BRITISH SOCIOLOGICAL ASSOCIATION (at the Royal Society of Arts, 6 John Adam Street, Adelphi, London, W.C.2), at 8 p.m.—Prof. Talcott Parsons (Harvard): "A Reconsideration of the Problem of Social Evolution".

Wednesday, April 28

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Annual General Meeting.

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 6 p.m.—Annual General Meeting; Dr. O. G. Sutton, F.R.S.: "The Development of Meteorology as an Exact Science" (Presidential Address).

PRESENTATION OF TECHNICAL INFORMATION DISCUSSION GROUP (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 6 p.m.—Discussion on "The Techniques of Communication by Film". Chairman: Mr. K. Lockhart Smith.

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "The Mathematical Content of Engineering Courses".

Thursday, April 29

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 2.15 p.m.—Discussion on "The First and Second Viscosities of Fluids" opened by Prof. L. Rosenhead, F.R.S.

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Dr. D. T. A. Townsend: "The New Education Scheme of the Institute of Fuel".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. A. Ratcliffe, F.R.S.: "The Physics of the Ionosphere". (The Forty-Fifth Kelvin Lecture).

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (in the Lecture Hall of the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Annual General Meeting. Mr. H. K. Purdie: "Control of Sound in Buildings—Requirements, Materials and Methods".

Friday, April 30

INSTITUTION OF CHEMICAL ENGINEERS (at the May Fair Hotel, Bedford Street, London, W.1), at 11 a.m.—Thirty-second Annual Corporate Meeting.

TECHNICAL INSTITUTE (at the Queen's University, Belfast), at 2.45 p.m.—Annual General Meeting. 2.45 p.m.—Dr. D. A. Gilbreath: "Cellulose Chemistry and the Textile Industry".

CHEMICAL SOCIETY (in the Chemistry Lecture Theatre, The University, Liverpool), at 5 p.m.—Dr. R. H. Manake: "The Story of the Isoquinoline Alkaloids" (Gomberg Lecture).

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Mr. S. B. Bailey: "Nodular Cast Iron: Its Present Position and Future Prospects as an Engineering Material, with Special Reference to its Suitability for Crankshafts".

UNIVERSITY OF LONDON (at the Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Dr. B. N. Jones: "Applications of Infra-Red Spectra to Organic Chemistry".

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (at the National Institute for Medical Research, The Ridgeway, Mill Hill, London, N.W.7), at 7 p.m.—Dr. B. K. Callow: "Medical Research and Fine Chemicals".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. M. Postan: "Medieval Science and Technology".

Saturday, May 1

ASSOCIATION OF CHEMICAL BIOCHEMISTS, SOUTHERN REGION (at the Radcliffe Infirmary, Oxford), at 2 p.m.—Demonstrations and Scientific Papers.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SENIOR LECTURER IN MATHEMATICS at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (April 30).

ASSISTANT LECTURER IN GEOPHYSICS OR CYTOLOGY—The Registrar, The University, Sheffield (May 1).

LECTURER and an ASSISTANT LECTURER IN THE DEPARTMENT OF PURE MATHEMATICS—The Registrar, The University, Liverpool (May 1).

LECTURER IN EDUCATIONAL PSYCHOLOGY at the University of Natal, Durban, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, May 1).

LECTURER or ASSISTANT LECTURER (preferably with qualifications and experience in chemical engineering or a branch of chemical technology) IN THE DEPARTMENT OF CHEMISTRY, at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 1).

LECTURER (preferably with special qualifications in survey) IN GEOGRAPHY—The Secretary of University Court, The University, Glasgow (May 1).

SENIOR LECTURER and a LECTURER (with an honours degree, and preferably with teaching and industrial experience) IN THE DEPARTMENT OF CHEMISTRY—The Clerk to the Governing Body, College of Technology, Birmingham (May 1).

SENIOR LECTURER (with qualifications and experience necessary to plan and supervise the teaching of organic chemistry up to honours degree standard) IN ORGANIC CHEMISTRY—The Principal, Royal Technical College, Salford 5 (May 1).

UNIVERSITY LECTURER IN THE DEPARTMENT OF ANIMAL PATHOLOGY, to undertake teaching and research in veterinary parasitology—The Secretary, Appointments Committee of the Faculty of Biology "B", Department of Pathology, Tennis Court Road, Cambridge (May 1).

DEMONSTRATOR (honours graduate in chemistry or biochemistry) IN CHEMICAL PATHOLOGY—The Registrar, The University, Leeds 2 (May 3).

LECTURER or ASSISTANT LECTURER IN AERONAUTICAL ENGINEERING, a LECTURER IN ELECTRICAL ENGINEERING, an ASSISTANT LECTURER IN GEOLOGY, and an ASSISTANT LECTURER IN MATHEMATICS—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (May 3).

SENIOR SCIENTIFIC OFFICER (with first or second-class honours degree in chemistry or equivalent, and at least three years postgraduate research, and a thorough knowledge of the mass spectrometer and experience in its application) IN THE CHEMICAL RESEARCH LABORATORY, Department of Scientific and Industrial Research, Teddington—The Secretary, Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting 84314/54 (May 6).

HEAD OF THE DEPARTMENT OF GEOLOGY at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 7).

LECTURER IN MATHEMATICS at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 7).

LECTURER IN BACTERIOLOGY AND VIRUS DISEASE—The Registrar, The University, Sheffield (May 8).

ASSISTANT ENTOMOLOGIST (with at least a second-class honours degree in science, with entomology as a major subject) at the Wattle Research Institute, University of Natal, Pietermaritzburg—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, May 15).

LECTURER or ASSISTANT LECTURER (preferably with qualifications in nuclear physics and electronics) IN PHYSICS—The Secretary, University College of the South-West, Exeter (May 15).

ASSISTANT LECTURER IN ANATOMY, to undertake teaching and research—The Secretary, University College London, Gower Street, London, W.C.1 (May 21).

CHAIR OF APPLIED ELECTRICITY—The Secretary and Registrar, University College of North Wales, Bangor, N. Wales (May 24).

READER IN PURE MATHEMATICS at King's College—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 25).

ASSISTANT LECTURER IN GEOLOGY—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (May 29).

CHAIR OF PHYSICAL OR INORGANIC CHEMISTRY—The Secretary, Queen's University, Belfast (May 31).

CHAIR OF PURE MATHEMATICS—The Secretary, The University, Birmingham 3 (May 31).

LECTURER IN PHYSICS at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 31).

BROTHERTON RESEARCH FELLOW IN PHYSICAL CHEMISTRY, and a RESEARCH ASSISTANT IN DYING, in the Department of Colour Chemistry and Dyeing—The Registrar, The University, Leeds 2 (June 1).

RESEARCH ASSISTANT IN MATHEMATICAL STATISTICS and a RESEARCH ASSISTANT IN NUMERICAL ANALYSIS, in the Department of Applied Mathematics—The Registrar, The University, Liverpool (June 1).

LECTURER (with a university degree, preferably in forestry, and practical experience of forestry in Great Britain or abroad) in **FORESTRY**—The Secretary, The University, Edinburgh (June 15).

DEMONSTRATOR (preferably with a degree and some ability in the experimental testing of rockets, ram jets, gas turbine combustion chambers, or other aspects of modern power plants) in **THE DEPARTMENT OF AIRCRAFT PROPULSION**—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks.

LECTURER (with a degree in horticulture or horticultural botany) in **HORTICULTURE**, in the Faculty of Agriculture, Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1.

METALLURGISTS, Experimental Officer grade (with at least H.S.C. in science subjects) in the Department of Atomic Energy, Harwell, near Preston, for development work up to pilot plant scale for the reduction or fabrication, including casting, mechanical working, welding and powder metallurgy, of unusual metals—The Department of Atomic Energy, Industrial Group Headquarters, Ruxley, Warrington, quoting 572.

PERRING SCHOLAR (preferably honours graduate or final year undergraduate in engineering, mathematics or physics) in **AERONAUTICS**—The Warden, The College of Aeronautics, Cranfield, Bletchley, Bucks.

PHYSICISTS (with a good honours degree and some experience or training in research, not necessarily in textile research) to work on textile problems—The Secretary, British Rayon Research Association, Barton Dock Road, Urningston, near Manchester.

SCIENTIFIC ASSISTANT (with a university degree, and a knowledge of two or more European languages, and ability to write clear, concise English), for duties which include abstracting world scientific literature on animal breeding, genetics and production—The Director, Commonwealth Bureau of Animal Breeding and Genetics, King's Buildings, Edinburgh 8.

SCIENTIFIC OFFICER (with a first- or second-class honours degree in physics or engineering, or equivalent qualifications, and at least three years postgraduate research experience) to supervise and participate in the activities of a group investigating the mechanical properties under stress (including tests to mechanical destruction) of prototype atomic weapons—The Administrative Officer, Recruitment Section, Atomic Weapons Research Establishment, Aldermaston, quoting 106/WGB/2.

SCIENTIFIC OFFICERS (3) (with first- or second-class honours degree in inorganic or physical chemistry, or equivalent qualifications), at the Water Pollution Research Laboratory, Department of Scientific and Industrial Research, Slough, to study the effects and treatment of pollution of rivers by waste waters containing inorganic and organic impurities—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.227/54A.

Optical Fused Quartz

Transparent fused quartz can be supplied for optical purposes as blanks for plates, lenses, prisms, etc., or as finished optical elements up to the highest degree of optical finish and freedom from strain.

It is manufactured in various grades, thus providing a suitable quality for each class of work ranging from the most exacting uses in ultra-violet optical determinations to ordinary work in the near ultra-violet and infra-red regions. We shall be pleased to recommend a suitable quality for your particular application.

MSE 'MAGNUM' CENTRIFUGE

- * capacity 1.5 litres
- * speeds up to 5,000 r.p.m.
- * large range of accessories
- * automatic timer

This is the perfect general-purpose larger capacity centrifuge. It will accommodate a swing-out head for six 250-ml. bottles and a large range of other swing-out, angle and basket-type heads with all usual buckets, adaptors and multiple carriers. Superspeed unit available. All controls are grouped in a single panel which can be hinged right down for easy access to the entire electrical installation.

Full details in MSE Publication 133, on request.

6" (OIL) MODEL (3-stage)
VACUUM 5×10^{-4} mm. Hg
SPEED 300-350 litres/sec.

1" (OIL) MODEL (2-stage)
VACUUM 5×10^{-4} mm. Hg
SPEED 9-10 litres/sec.

Though we produce "SPEEDI VAC" vapour pumps many feet in height, which are in world-wide use our smallest models are no less giants behind large-scale production. In the laboratory they are at work solving production and new process problems. Amongst the many constructional advantages which have made "SPEEDI VAC" pumps famous are the INTEGRAL "BOOSTER" STAGES, BAFFLE ISOLATION VALVE... SIMPLE RAPID VACUUM CONNECTIONS.

These Models can be delivered within one week complete with Valves, Traps, Backing Pumps, and all Accessories, if required.

for better vacuum service... **W. EDWARDS**

"MAGNAPOISE" ADJUSTABLE MAGNIFIER

This new stand magnifier has every conceivable adjustment enabling the lens to be instantly placed in the exact position as required by the user. The "Magnapoise" incorporates the well-known Terry Anglespoise Band and is supplied in black featherweave finish; the heavy metal base is perfect rigidity. It can be used as a work inspection magnifier, examination of raw material, of small parts in production, and for inspection. Ideal for use in the first aid room, for hospitals, and laboratory also for use by typewriters, for proof-reading, etc. Available with lenses of different sizes and magnification. Fuller details gladly sent on request.

SCIENTIFIC RESEARCH AND INDUSTRY IN BRITAIN

THE deepening anxiety which marked the two preceding reports of the Advisory Council for Scientific and Industrial Research is appreciably diminished in the report of the Advisory Council for 1952-53, a survey of which appears elsewhere in this issue (p. 797). Difficulties arising from the exiguity of current resources are again recorded, and it is once more apparent that the nation's economic development has been hindered by restrictions imposed upon the activities of the Department of Scientific and Industrial Research during recent years which retarded its plans for the development, for example, of the Hydraulics Research Station, the Water Pollution Research Laboratory, and the Mechanical Engineering Research Organization. The Advisory Council does not recapitulate these frustrations, nor does it pretend that the new arrangements for the five years beginning April 1, 1954, announced on November 27, 1953, will necessarily mean the end of all difficulties. The broad effect of those arrangements will be to bring the Department's post-war plans nearly to completion by 1959, thirteen years after they were originally approved in 1946. Further, the Advisory Council understands that it may now advise on the future activities of the Department on a basis essentially that for which it pressed in its report for 1950-51; the provision which allows it to carry over unspent balances from one year to another gives it the flexibility which it has repeatedly stressed and which had already received strong support in debates in Parliament.

None the less, the increase in expenditure proposed in the estimates for 1953-54 and for 1954-55 is not large, either in relation to the Department's net expenditure of £5.2 million in 1952-53, or to the national expenditure as a whole. Even in 1959, the net annual resources of the Department are only expected to exceed £6 million very slightly, whereas in 1951 the total expenditure on industrial research and development was estimated in a recent debate in the House of Commons as £268 million, of which probably about £70 million was on civilian research. A recent survey made by the Harvard Business School estimated that industry in the United States spent in that year 2,500 million dollars on research and planned to increase this to more than 3,000 million in 1953.

Thus, the fact that the Advisory Council considers that the new arrangements afford firm ground on which to advise how best to allocate the resources it expects to be available and on which to base forward policy with reasonable assurance that recommendations will not be stultified by lack of means for carrying them to fulfilment, cannot be taken to imply that the resources at the disposal of the Department are adequate for the discharge of the responsibilities which are appropriately laid upon it. On the contrary, the new arrangements make the more urgent and imperative a continuing review of the functions of the Department and the resources at its disposal in relation to the research organization

of Great Britain as a whole, and the resources available to meet the needs of scientific and industrial research and development in all the varied fields of defence, economic development and welfare. That need is well brought out in the present report, for the Advisory Council recognizes very clearly the dynamic character of some of the Department's activities, such as those of the National Physical Laboratory, with the consequent budding off of new sections from time to time. Such changes, moreover, need not necessarily be solely within the Department. They could equally lead to the shedding of responsibilities, as may well follow from one development specifically noted in the report—the formation of companies, analogous to the National Research Development Corporation, to which particular research associations can transfer their responsibilities for economic development of their inventions or discoveries.

In another field, the educational responsibilities of the research associations are assuming an importance, particularly in relation to technological education, which may well render desirable some assessment of the position of the research associations in relation to the expansion of higher technological education apart from their contribution to research, and consideration of the resources to be apportioned to that field. This aspect of the work of the research associations derives its importance at least in part from their place in furthering the more effective utilization of existing knowledge as distinct from the acquisition of new knowledge. Much stress has been laid in recent years on the value of the liaison work of the research associations in furthering the exploitation of science by industry. This work receives special emphasis in the current report, which directs particular attention to the work in this connexion of the Intelligence and Information Division in the headquarters office of the Department.

On the research side, the report brings out more clearly than preceding reports the magnitude of the assistance which the Department is rendering to the universities through its grants for special investigations. Outside the field of nuclear physics, much the largest of these grants is the £230,000 over four years to the University of Manchester for the construction and running costs of the radio-telescope at Jodrell Bank; but grants towards capital and maintenance costs for nuclear physics in universities of the United Kingdom during the quinquennium 1952–57 exceed two and a quarter million pounds. This figure looks small enough against the estimates for the Department of Atomic Research, the £53 million of which for 1954–55 include £4 million on civil research and development and £1.8 million for work for the Department by industry and the universities, as does the quarter of a million pounds or so awarded in grants to students and others in the university budgets; but nevertheless, the contribution of the Department is sufficiently large to indicate the repercussions which could flow from sudden curtailment or reorientation of its activities. Moreover, with the formation of the European Organization for Nuclear Research, the Department will be the

medium for official relations with the Organization, and will be responsible for co-ordinating United Kingdom policy on the scientific and administrative questions involved. The United Kingdom's contribution to the budget of the Organization is to be borne on the Department's Vote, and is expected to average £350,000 a year during the seven years while its laboratory is being built, and thereafter some £180,000 a year. In the 1954–55 estimates for the Department, £360,000 is provided for this purpose.

This new interest of the Department indicates, in a minor way, the soundness of the Government's decision to place the major responsibility for the oversight of the development of atomic energy, and particularly for seeing that proper account is taken of the various applications of atomic energy and of nuclear research in the universities, on the Lord President of the Council. The magnitude of these responsibilities for the wise apportionment of the limited resources of Britain in scientific and industrial research and development is clear from the present report, quite apart from those additional responsibilities which the Atomic Energy Corporation Bill will place upon him. Ultimately, with the advice of the Advisory Council for Scientific Policy, he is responsible for the general co-ordination of research and development activities on which the sum of almost £200 million, according to the Civil Estimates, is to be expended in 1954–55. This sum, moreover, does not include any allocation from the Vote for the Atomic Energy Corporation, but it does include some £18 million from the Navy Estimates and £550,000 from the Air Estimates (£315,000 for meteorological research and £235,000 for medical research out of the £748 million provided for production and research in the Defence budget).

To get the exact perspective in which to assess the importance of the Department of Scientific and Industrial Research, it must be emphasized that, even were it possible to obtain an exact figure for the nation's expenditure on scientific and industrial research, we would have still to take account of the Department's contribution in the field of education and also in that of intelligence and in furthering the exchange of information and the use of existing knowledge by industry. When regard is had to all these functions, all of which to some extent fall within the scope of the Lord President's Office, the provision of only £13,300 for that Office in the Civil Estimates suggests that it is under-staffed and ill provided with the means for securing that the national effort in these fields is kept in balance fully concerted.

Considering first the £6,267,210 provided for the Department in 1954–55 from the point of view of research, it must be remembered that this increase of £578,379 includes £360,000 for European nuclear research. It also includes £114,500 for American Aid—Technical Assistance Schemes and £124,400 for the promotion of productivity in the same way, part of which is a contribution to the third function of the Department rather than to research. Some £221,050 is for research to be carried out extra-departmentally, and an additional £91,500 is pro-

vided for the research associations, bringing the total annual income of these associations within sight of £5 million. It should be remembered, however, that the Ministry of Supply alone provides more than £98 million for research and development by industry and the universities, etc., and that the expenditure of the Department's various stations has to be considered against expenditures on research of other Government departments in the same field: the quarter of a million pounds expended on fuel research, for example, must be viewed against the £879,900 expended on research and development by the Ministry of Fuel and Power. Nor does this latter figure take account of any expenditure on research by the nationalized industries themselves.

Such expenditure falls outside the £200 million for research and development shown in the Civil Estimates, as does any income which the universities and colleges receive over and above the £27,932,500 provided in the Civil Estimates for 1954-55. There is no estimate available of the total expenditure of the universities on research; but, at least outside the one field of nuclear research, the grants from the Department of Scientific and Industrial Research cannot play any very substantial part. Their importance probably lies less in their magnitude than in contributing to the furtherance of investigations in neglected fields of decisive national importance.

That could equally be true of the Department's contributions in research generally, both in the applied and the fundamental fields. In magnitude its efforts are small compared with what is done elsewhere: with wise direction their importance can be out of all proportion. This consideration, with the fact that neither such surveys of the work of the research associations as the Advisory Council for Scientific and Industrial Research has made, nor the survey of industry and science in the Greater Manchester area carried out by the Manchester Joint Research Council, have brought to light any evidence of badly misdirected work or poor selection of objectives, endorse the value of the provision for continuity of work which the new financial flexibility of the Department makes possible.

The total expenditure of the Department is probably less than ten per cent of the expenditure on industrial research in Great Britain, though its proportion to the expenditure on scientific research, apart from nuclear research, may well be higher. Expenditure on fundamental research in the United Kingdom was estimated in 1951 as no more than £1.5 million. There seems to be no reason, moreover, in the light of the survey made by the Manchester Joint Research Council, for supposing that scientific and technical man-power is being used wastefully, though the Department's educational activities could well contribute towards increasing the efficiency of utilization of our resources in scientific and technical man-power. Here, however, it is even more difficult to assess the magnitude of the Department's contribution, particularly as that made through the research associations may well become even more important than its system of maintenance grants.

These grants were increased from October 1, 1953, and the thousand or more current grants represent a valuable contribution to the training of scientific and technical man-power.

While the value of the research associations in relation to the training of technical man-power for industry has only come to be recognized fully in recent years, the Conference held last November showed that the importance of their contribution to the expansion of higher technological education is now widely appreciated. Means have still to be formulated for securing that this contribution is fully effective, and on this point the Advisory Council may well comment in a subsequent report. It should also be explored by the Advisory Council on Scientific Policy in its inquiries into the development of technological education; and it would appear possible that the system of maintenance allowances might be used, among other measures, to alleviate the serious shortage of science teachers which is endangering the future supply of scientists and technologists in Britain.

In its present report, however, the Advisory Council is more concerned with the intelligence functions of the Department and its contribution to the more effective exploitation of science by industry. Little information is available as to the resources deployed by the Department for this purpose. Expenditure on headquarters administration, including the Intelligence and Information Division, is only £213,000, and there is no indication of any immediate intention of expanding the Division. Moreover, the effectiveness of the work of such a Division depends largely on the state of the library and information services of the country generally. In this connexion it must be remembered that the Government has shelved the proposals for a Science Centre in London, in spite of the handicap at once imposed by the delay in implementing the scheme for a national library of science and invention supported by the specialized libraries of the learned societies. The Department, it is true, does something to further the improvement of information services through its grant to the Association of Special Libraries and Information Services, and the Director of that Association has pointed out that where the Association's functions touch the activities of the Intelligence and Information Division every care is taken to avoid duplication or overlapping.

That, however, is a small matter compared with the assistance which an adequately housed national reference library of science and technology, linked with regional libraries and the libraries of the learned societies, could render to the functioning of the Intelligence and Information Division or of the library and information services of industry itself. The failure of the Advisory Council, in its reference to this aspect of the Department's activities, to press the Government to reverse the decision regarding the Science Centre is disappointing. Such a Centre, with its interlocked central and specialized libraries, would directly assist in making research results and research facilities widely and effectively known, in ensuring that they are used and applied more quickly by

industry and Government, and that research and development are undertaken on matters of real national importance so that major benefits accrue with increasing speed and efficiency. These are the prime interests of the Intelligence and Information Division. The Science Centre would do more than provide mechanical means for furthering them. It would supply a meeting place for informal contacts and discussions, which are more important than any mechanical devices for striking out new ideas and formulating creative projects.

The duties of the Intelligence Division, which were redefined in 1950, are considered at some length by the Advisory Council in the present report. The Division's responsibilities for the organization and maintenance of liaison with overseas countries are growing; nevertheless, the national reference library of science and invention, located adjacent to the Department, as contemplated in the scheme for the Science Centre, would materially assist the efficiency of all sections of the Division's work. Apart from maintaining the Headquarters Records, Library and Information Services and undertaking scientific and technical surveys and inquiries as required, the Intelligence Division has more recently taken over responsibility for the publications and publicity work of the Department. Moreover, it is not only expected to keep watch on scientific progress and direct attention to advances that may be capable of industrial application: by maintaining touch with current economic and sociological affairs and Government policy in these fields, it is expected to ensure that the Department is kept informed of needs, and that the attention of Government Departments, and especially the central economic staff, is directed to the implications of scientific and technical advances.

Consideration merely of those aspects of the Division's work which are specially mentioned by the Advisory Council in this report suggests that to implement the work of this Division on the scale desirable in the national interest could absorb well-nigh the whole sum at present expended on headquarters administration and a large proportion of the half-million or more pounds by which the Department's budget is expected to increase during the next few years. The investigations for which the Division has been responsible during the past two years in regard to the conservation, and substitution, of raw materials which were either scarce or involved currency difficulties when purchased abroad have already offered savings which probably offset by many times the present expenditure of the Division. The Advisory Council refers, for example, to the discovery of economic uses for waste sulphuric acid, and to an investigation of the technical and economic possibilities of recovering non-ferrous metals from the cinders of pyrites roasting plants, which greatly increased in numbers as a consequence of the recent sulphur shortage. Economic assessments have also been made of long-term trends in the demand and supply of selenium, germanium and vanadium, and the possibilities of increasing supplies by technological improvement have been examined by the Division.

The other aspect of the Division's work stressed by the Advisory Council is that relating to industrial productivity, both in regard to the work of the two joint committees with the Medical Research Council on human relations in industry and that on individual industrial efficiency. A number of research projects have already been placed with universities and research organizations, and the work of the Intelligence Division has clearly contributed much to the selection of the broad programmes of research on which these committees are concentrating their attention. Some of this work is being assisted by grants made available to the Department over the next three years from Conditional Aid funds, and in this context also falls the work of a committee appointed to recommend suitable projects for investigation in production economics and the survey of technological resources and the requirements of industrial firms in the Greater Manchester area carried out by the Manchester Joint Research Council, towards which the Department is contributing a grant of about £3,000.

Both the present report from the Department and that from the Manchester Joint Research Council testify to the continuing value of such inquiries and of this intelligence work and liaison work in general in facilitating the utilization of existing knowledge by industry. Nor does either report warrant any belief that this will be a rapid process, even if the scale of such intelligence work is considerably extended. Such activities clearly lie outside the research functions of the Department as strictly understood; but they are no less important, and it would be well if their cost were more clearly indicated. There are obvious difficulties in indicating that figure precisely, since much work of this type is included in the budgets of the research associations. None the less, an attempt at an approximate figure is desirable, particularly in view of a passage in the account of the work of the Intelligence and Information Division which suggests a tendency to rely on Conditional Aid funds to meet the industrial demand for advisory service and information on such matters as methods and time study, materials handling, etc.

The prominence given to this aspect of the Department's work in this year's report from the Advisory Council is thus welcome. The Advisory Council, in stating that one of its main tasks in the coming year will be to consider how to give effect to the recommendation in the last report from the Advisory Council for Scientific Policy regarding the extension of the use of research and development contracts in the modernization of industry and exploitation of scientific discoveries, again stresses the value of the liaison and advisory services of the research associations. Even if precise figures cannot be given for the educational and information work of the Department, it would seem worth while for the Lord President's office to attempt to offer Parliament a picture of the national expenditure in these varied fields. When the Department's expenditure reaches the anticipated figure of £8 million, much of it will be incurred on objectives which cannot properly be classified as research and should be shown under information or

intelligence, or under university or technological education. Even now the Advisory Council's estimate that the present activities of the research associations amount to about one-tenth of the total research and development activities of civil industry seems rather optimistic. An attempt to show the breakdown of the Department's expenditure not simply by its own Divisions but by such categories as research and development, education, information, liaison and intelligence, would permit a sounder judgment as to whether sufficient effort is being devoted to the latter activities. It is not only in the prosecution of research, but also in training man-power for research and in the provision of information and stimulation of thought that the Department is making an essential contribution to industrial development and the improvement of productivity in Great Britain. Its contribution in these fields has to be judged against the magnitude of the effort which is being made elsewhere in the country, and in the main it should be possible to make the comparison from information available within the organizations for the co-ordination of the activities of which the Lord President of the Council is ultimately responsible. Such an assessment, moreover, is an essential element in the formulation of constructive policy in the field of research and development, in technological education, and in the provision of adequate means for the flow of information. The underlying questions and the appropriate means by which policy is to be implemented should now be very much in the minds of the Lord President and his advisory councils in order to be sure that Britain's effort in these fields is adequate, wisely directed and so concerted as to avoid duplication and waste of effort or resources.

SOCIAL CONDITIONS AND THE DEVELOPMENT OF SCIENCE

Essays on the Social History of Science
 Edited by S. Lilley. (Centaurus, Vol. 3, 1953, Number 1-2.) Pp. 182. (Copenhagen: Ejnar Munksgaard, 1953.) 30 kroner.

THIS book contains twelve essays in English by eleven authors on various features of the history of science from the earliest times to the present, with special reference to their social aspects. There is also a brief introduction purporting to describe the origin and character of the volume. There is much in the book of great interest and value which it would be wrong not to mention. In a brief review, however, attention must be focused on the predominant tone, and, despite its intermittent utterance and the merits of intervening accents, of this there is no doubt. It is clearly sounded by the writer of the introduction: "the fundamental trend of social evolution and the position of science in it . . . is the development of the means of economic production which primarily determines the development of all other human activities, not excluding intellectual and spiritual development. I regret that so many prominent scholars are too timid to accept this general inference as a guidance in their studies" (p. 11).

It may, of course, be sagacity rather than timidity that accounts for this lamentable failure, but, however that may be, the editor's team includes a goodly company of brave men prepared to follow the trumpet-call wherever it leads them. Unfortunately, their logic and perspicacity are not always equal to their courage. Two qualities of the book specially strike the unconditioned reader: first, a tacit change of meaning of a phrase before its use in an argument; second, blindness to the major elements of a process and exaltation into pre-eminence of minor details.

On p. 12, for example, we are invited to accept a definition of science as "in effect, a traditional body of observations, expressed in mutually intelligible symbols . . . and providing rules for concerted action on a common environment—in other words a sort of ideal map or conceptual working model of reality serving as a guide to action". Few would quarrel with this, whether or not it could be improved upon. But two pages later we read: "Social relations are thus inevitably common knowledge, and only common knowledge is a serviceable guide to concerted action". "Common environment" has now become "common knowledge". The man who goes voyaging through strange seas of thought alone is no longer a scientist, and can be made to toe the line. Moreover, common knowledge is identified with social relations, and the way is clear to claim science as essentially a social matter and therefore properly subject to control by the State. The writer does not here take this final step, but he makes it almost irresistible, and others have taken it.

Another example is found in the discussion (p. 59) as to whether a new scientific development is called forth by the internal state of science or by social needs. The writer claims that both are necessary, but the only evidence given for the latter is the obvious fact that, if the social organization regards the development as dangerous and removes the opportunities for making it, then it will not occur. Because social needs can hinder progress, they must be necessary to produce it. On the same grounds, prussic acid can be proved necessary to life.

Oversight of the obvious with magnification of the trivial is illustrated by the statement (p. 61) that the "essential factor" in the discovery of the conservation of energy was "the importation into science of habits of thought that were created by the social agency of the Industrial Revolution". It seems not to have occurred to the writer that the conservation of energy was discovered first of all because energy is conserved, and men intent on finding out what remains constant amid changes must inevitably discover it. The utmost that extraneous influences can do (provided they do not prevent scientific research entirely) is slightly to affect the time of discovery and perhaps the terms in which it is expressed. After reading the account given here, an uncritical reader would probably conclude that under other social conditions it would have been discovered that energy was not conserved.

Similar perversity is seen in the lengthy discussion (pp. 65-9) of the reasons why Galileo and not Leonardo laid the foundations of modern science. The writer sees only two possible explanations, "one in terms of the internal development of scholastic science, the other in terms of social changes". Again, it does not occur to him that at least 99.9 per cent of the reason was that Leonardo was Leonardo and Galileo was Galileo, and that if their dates had been interchanged Galileo would not have painted the

Mona Lisa and Leonardo would not have translated the book of Nature into the mathematical language. The fact that none of their countless contemporaries, though exposed to exactly the same states of scholastic science and social changes, produced anything approaching their achievements would have made this obvious to anyone not bemused by a theory already impregably fortified against the onslaught of facts of any kind.

The influence of scientific knowledge on social history has been badly overlooked in the past, but the fault is not rectified by exaggerating into a major cause the slight effect of social changes on the direction of advance of scientific knowledge. The path from this error of State control of science is fatally easy. If I were not too timid I would express myself strongly on this matter.

HERBERT DINGLE

ARCHAEOLOGY OF LACHISH IN THE NEAR EAST

The Wellcome-Marston Archaeological Research Expedition to the Near East

Lachish 3 (Tell ed-Duweir): The Iron Age. By Olga Tufnell. With contributions by Margaret A. Murray and David Diringer. Text, Pp. 438. Plates, Pp. 10 + 130. 2 Vols. (London, New York and Toronto: Oxford University Press, 1953.) £8 8s. net.

It is now generally accepted that Tell ed-Duweir marks the site of the ancient city of Lachish, which was frequently mentioned in the Old Testament and twice in the ancient Assyrian records. The present volume, well printed and illustrated with excellent photographs, describes the successive foundations of the city and the changes which occurred from approximately 1180 B.C. to the middle of the fourth century. During that long period there seem to have been at least five major rebuildings, of which architecturally the most interesting are those between periods 3 and 1.

There is some doubt as to who may have been responsible for the heavy burning of the city in the twelfth century B.C., though inevitably that event must in some way be correlated with the Peoples of the Sea; but whether or not the destruction was due to a punitive attack by the Egyptians cannot be decisively proved.

In levels 4 and 3 the contents of the tombs as well as what was discovered in the city show that the place was in close contact with Egypt, and the archaeological evidence would suggest that the phase of economic decline which occurred towards the end of this period may well have been due to the fact that it was cut off by increasing pressure of Assyria on North Syria from any northern trade.

In the next phase, which covers the eighth century B.C., there occurs a wheel-burnished pottery of very good quality, a type which had come into general use in the city of Samaria in about 800 B.C. and is a means of providing a valuable synchronization. To this level, too, belongs a series of early Hebrew characters on royal stamps, and these form part of the dating evidence used as a basis for the chronology by Dr. David Diringer.

The end of period 3 is clearly defined by a violent burning and destruction. The evidence supports the author's conclusions that this event is most probably to be ascribed to the conquest by Sennacherib of the

city in 700 B.C., an event recorded not only in the Old Testament and the Assyrian records, but also actually illustrated on a bas-relief discovered by Layard at Nineveh. It is therefore significant that the architecture of this phase was obviously related to a contemporary style in Assyria. The most important of the monuments is a well-dressed limestone podium surmounted by mud-brick, which is characteristic also of the Sargonid occupations at Khorsabad and Nimrud. It appears, however, that this architectural style, so strikingly illustrated in Assyria during the eighth century B.C., has a longer history behind it in Palestine, and this discovery at Lachish therefore raises an attractive problem.

No less interesting architecturally is a stone building in the latest level I, which has been appropriately named the residency of the Persian governor. This is rightly thought not to be Achaemenian in style, but to reflect a Syro-Hittite origin. Here, however, we may perhaps also look to Assyria and find a parallel in a spacious residency of the sixth century B.C. discovered by André at Assur.

This volume contains a great variety of significant material which has been well set out for study by scholars, and in itself provides a mine of important information. A debt is owed to the many authorities who have contributed to this work, but most of all to the devoted labours of Miss Olga Tufnell, who has in exemplary fashion set out the results of this expedition and overcome the very great difficulties which must beset anyone who attempts publication when the leader no longer survives to complete his task. The Wellcome-Marston Trustees are to be congratulated on this admirable achievement.

M. E. L. MALLOWAN

STUDY OF MANAGEMENT

The Principles and Practice of Management

Edited by E. F. L. Brech. Associate authors: R. M. Aldrich, A. W. Field, J. Maddock, and Frank L. Woodroffe. Pp. xvi + 752. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1953.) 50s. net.

SCIENCE or art: academic or practical: graduate or man from the shop floor? These are among the questions which are being hotly discussed in industry to-day; the answers may well decide the future of industrial endeavour in Britain and, inseparably, the whole pattern of the British way of life.

For these and other reasons "The Principles and Practice of Management" is an important book. In it the editor and his associate authors unflinchingly declare their faith that, while management at all levels must be learned by practice, there is also a considerable body of knowledge which can be studied and which no competent manager of to-morrow can afford to ignore. They have been jointly concerned to present some of this knowledge and, for the attempt alone, are to be warmly commended.

The book is divided into six parts. The first presents the analytical framework within which the whole process of management is reviewed and the underlying principles examined. The last is concerned with management in practice and deals with such topics as the functional principle, the use of committees in organization and the place of management in national affairs; both parts have been

contributed by the editor. Between the general principles and practice of management come sections dealing with what are described as the major divisions of management: distribution, production, personnel and control. Each of these has been contributed by a specialist with considerable practical experience in his own field.

Under distribution, the author includes all direct and incidental sales activities, advertising, public relations, warehousing, stock control and transport. The author of the section on production describes such activities as design, production methods, work measurement, production planning, production control, supervision, buying, store-keeping, works maintenance and inspection. The personnel function of management is described as the nervous system of the organization and includes such topics as industrial relations, training and promotion and withdrawals, physical working conditions, employee services and the mechanics of arbitration. Control is mainly concerned with the financial aspects of management and deals with such processes as the preparation and use of budgets, the application of budgetary control, cost control and clerical management.

In a book with such a wide range of authorship, it is not surprising to find over-lapping and variation in principle and details between author and author; the editor has, in fact, made no attempt to circumscribe the authors so that they would write to an agreed body of principles. What is surprising is that so much of the over-lap consists of tedious repetition and that much of the text is loose, contradictory and, too often, inaccurate.

More serious is the claim that this book should be regarded as the reference book for those wishing to practise 'scientific management'. The whole book is unquestionably founded upon good practical experience; this does not preclude the possibility that other students of management with equally good practical experience might present their ideas on management in a different way. It is questionable, too, whether this essay in empiricism might not have served a better purpose if it had appeared, not as a declared reference book, but as a series of much shorter volumes dealing with particular aspects of the management function; each of the volumes could then be superseded as new knowledge and experience are gained in a branch of study which its most ardent exponents still believe to be in the very early stages of growth.

T. H. HAWKINS

INFORMATION THEORY MADE EASY

Probability and Information Theory, with Applications to Radar

By P. M. Woodward. (Pergamon Science Series: Electronics and Waves—a Series of Monographs.) Pp. x+128. (London: Pergamon Press, Ltd.; New York: McGraw-Hill Book Co., Inc., 1953.) 21s.

EVEN an author with Mr. Woodward's ability of explaining complicated matters in simple and attractive language is rather too severely handicapped if he has to explain information theory on 125 small pages, leading up to three specialized chapters on radar, and if on the way he has to explain all the mathematics required, from probability to Fourier

integrals. In this process of condensation and popularization a few things must go by the board. Mathematical rigour is the first victim, and the least regretted. A more serious loss is, in the present case, that this little book may not be a very suitable introduction to the more recondite works on communication theory. Mr. Woodward has followed an 'easy way' of his own invention, which is smooth enough as far as it goes, but is likely to become an impasse later on.

Statistical communication theory centres on Claude Shannon's fundamental theorem: there exists a maximum amount of *certain* information which can be transmitted per symbol *on the average* from an ergodic source through a noisy channel. This maximum can be approached to any limit by suitable coding methods, which deal with the messages in large lumps of symbols. The theorem says nothing about individual messages; evidently a single, short message can convey no certainties whatever.

If $p(x)$ is the probability of a symbol x being sent, if $p(x,y)$ is the joint probability of x being sent and y received, and if $p_y(x) = p(x,y)/p(y)$ is the conditional probability of x having been sent when y is received, the upper limit is

$$H(x) - H_y(x) = -\sum p(x) \log_2 p(x) + \sum p(x,y) \log_2 p_y(x)$$

measured in 'bits' per symbol, that is to say in terms of binary decisions. It is worth while stating this theorem in some detail, because it comprises implicitly perhaps 90 per cent of present-day statistical communication theory—among others the results of Woodward and Davies on radar information. There is, of course, the danger that one may be inclined to forget one or the other of the unfamiliar qualifications in such a long statement.

Mr. Woodward's 'easy way' panders to this human weakness by giving a *detailed* interpretation to the terms which occur in the theorem, and suppressing, at least temporarily, the all-important stipulation 'on the average'. In his view, if a symbol x is received whose *a priori* probability was $p(x)$, there is a transfer of information of the amount $\log_2 p(x)$ bits. If the transmission is marred by noise, one must deduct from this the logarithm of the *a posteriori* probability of x being meant, which is less than certainty. This is a detailed interpretation, quite similar in nature to Ampère's law of the interaction of two 'current elements', or to Poynting's picture of the energy flow, which is a detailed interpretation of the energy integral in Maxwell's theory. The danger of these detailed pictures is that one forgets that they operate with undefined and undefinable quantities. 'Current elements' do not exist, the energy flow density cannot be measured, and information transfer is an empty word until one averages it over long messages. Yet, the didactical and stimulating value of this sort of approach cannot be denied. After all, even Maxwell's field theory is an over-detailed picture, whose purpose is to account for the energy and momentum exchanges between charged particles, which alone are measurable. One must forgive Mr. Woodward all his verbal operations for a stimulating sentence such as "the ideal receiver must directly display the *a posteriori* probabilities".

By and large, this little book admirably fulfils its purpose of making a tasty dish for the moderately mathematically minded engineer out of the driest and most indigestible fare, and giving him a little intuitive understanding in preference to a full-blown inferiority complex.

D. GABOR

THE BRITISH FUNDAMENTAL GRAVITY STATION

NEW SITE AT THE NATIONAL PHYSICAL LABORATORY, TEDDINGTON, MIDDLESEX

THE British National Gravity Base was for many years situated at Greenwich Observatory. Originally a site in the Record Room was chosen, but, in 1927, a new position was selected some 300 metres east of the Observatory in the old Magnetic Pavilion. This building has now been demolished, and in view of the fact that the Royal Observatory is being transferred from Greenwich to Herstmonceux a new

site had to be found. Meanwhile, in accordance with a resolution made by the International Gravimetric Commission at its meeting in Paris in September 1953, the British National Gravity Base was named the British Fundamental Gravity Station.

At the Ninth General Assembly of the International Union for Geodesy and Geophysics held in Brussels in 1951, a resolution was passed by the International Association for Geodesy urging "each country to ensure that their primary station is established in a suitable permanent position".

At its meeting on June 30, 1952, the British National Committee for Geodesy and Geophysics resolved that the British Fundamental Gravity Station should be at the National Physical Laboratory, Teddington, Middlesex, on the site of Clark's (1930) absolute determination of gravity in Room No. 11 of the Metrology Division building. The geodetic co-ordinates (see Figs. 1 and 2) and height of the pillar which Clark used are:

Latitude	51° 25' 18.6" N.
Longitude	0° 20' 21.4" W.
Height (Newlyn datum)	9.23 m.

Fig. 1

The pillar, which is situated in the south-east corner of the room, has most of its upper surface at floor-level. There is an extension of height 70 cm. at one end; but this is a later addition and has no connexion with Clark's experiments. Most of the relative measurements of gravity at this site have been made with apparatus standing on the floor, and it is recommended that this practice should be continued. The mean height of the centre of gravity of Clark's pendulum was 95 cm. above floor-level. It was therefore subjected to a mean acceleration of gravity 0.29 mgal. less than at floor-level. The pillar is set 6 ft. into the subsoil and under normal conditions is very steady; but occasionally some disturbance due to nearby building work and heavy machinery has been noticed (Clark, 1930, Cook, 1952).

If circumstances arise which make it inconvenient to observe on Clark's pillar, there are two subsidiary sites nearby which are well compared with the Fundamental Gravity Station:

(1) On the roadway immediately outside the west door of the main east-west corridor of the Metrology Building (Fig. 2) approximately 30 m. west of the Fundamental Gravity Station. The geodetic co-ordinates are:

Latitude	51° 25' 14" N.
Longitude	0° 20' 23" W.
Height (Newlyn datum)	9.24 m.

The value of gravity at this site is known to be the same as at the National Base within ± 0.02 mgal.

Fig. 2

(2) On the west side of the road in Avenue Gardens, Teddington, about 20 m. from the junction with Park Road (Fig. 2). The geodetic co-ordinates are:

Latitude $51^{\circ} 25' 14''$ N.
Longitude $0^{\circ} 19' 55''$ W.
Height (Newlyn datum) 9.60 m.

The value of gravity at this site is 0.04 ± 0.02 mgal. greater than at the National Base.

PITHECANTHROPUS, MEGANTHROPUS AND THE AUSTRALOPITHECINAE*

By PROF. G. H. R. von KOENIGSWALD
University of Utrecht

A VERY important group of higher Primates has been discovered in Africa, the Australopithecinae¹. They include *Australopithecus*, *Plesianthropus* and *Paranthropus* from South and most probably "*Meganthropus africanus*"² from East Africa. The position of *Telanthropus* from the *Plesianthropus*-layers of Swartkrans is still under dispute.

The large amount of material now at hand leaves no doubt that the Australopithecinae are members of the Hominidae. With this group they share the upright gait, which can be concluded from the pelvis, used by *Plesianthropus* and *Paranthropus*, and several important peculiarities of the skull and the dentition. The *Australopithecus* from Makapansgat owes the name "*prometheus*" to Dart's suggestion that he knew the use of fire, which, however, was disputed by Broom³. Dart has also suggested that certain battered ungulate humeri from the same site are evidence of a "predatory implemental technique"⁴; however, exactly the same type of damage is caused by hyenas⁵, which are also known from Makapansgat⁶.

* Summary of a lecture given at University College, London, on March 12.

The oldest known, undoubtedly human beings, are the *Pithecanthropi* of Asia, including *Pithecanthropus*, *Sinanthropus* and *Meganthropus*. Do the Australopithecinae represent an ancestral type? Are they really older and more primitive?

First of all, the known Australopithecinae are, geologically, not older than *Meganthropus* and *Pithecanthropus modjokertensis* (not *Pithecanthropus robustus*) from the Lower Pleistocene of Java⁷. In at least two of the South African sites, Kromdraai and Swartkrans, the horse, *Equus*, is found, which is the best guide fossil for the Pleistocene, and at Sterkfontein and Swartkrans we find an extinct carnivore, *Lycyaena*, which even in Europe existed until the Villafranchian⁸. There is no definite proof that any of the other sites is really of Pliocene age.

The best-known hominid from the Lower Pleistocene of Java is *Pithecanthropus modjokertensis*. This form has retained the 'simian gap', which is a very primitive characteristic which might be expected in an early human forerunner; for Remane, in a very careful study, has shown that even in the dentition of modern man there are peculiarities due to his forerunners having much better developed canines⁹. This gap has already disappeared in the full-grown Australopithecinae—although it seems to be present in the deciduous dentition of *Australopithecus africanus*; but while this *Pithecanthropus* in spite of the primitive dentition possesses a typical human entrance to the nose with a well-developed nasal septum, in the Australopithecinae—I quote from a description of *Paranthropus crassidens*—"except that the inner parts of the premaxillaries pass considerably further back, the resemblance of this region to that of the chimpanzee is considerable"¹⁰.

The incisors in *Pithecanthropus* are well developed. In the Australopithecinae they are much reduced, in some cases even below the minimum values known for modern man. Minimum values for central incisors are, for *Paranthropus crassidens* and *Homo sapiens*, upper 7.5 and 8.0 mm., lower 5.0 and 4.6 mm., respectively. The relative values are much higher, as the average length for the first lower molar in *crassidens* is 15.0 mm., in modern man 11.1 mm. The canines are of about the same size in both groups.

In modern man the first lower premolar is only a little smaller than the second (in some Eskimos we still find the reverse), the average being 0.3 mm. But it is 1.3 mm. in *Paranthropus crassidens*. In *Sinanthropus* the first premolar is largest, also in *Meganthropus*, and generally in all anthropoids. This surely is the primitive condition. As a whole, in the Australopithecinae the incisor-canine-premolar group is more reduced not only as in *Pithecanthropus* but also more than in modern man. In connexion with this reduction, the dental arcade shows a typical shortening, which has been demonstrated by Le Gros Clark¹¹.

In spite of all these specializations, the roots of the premolars in *Paranthropus* do not differ in number from those observed generally in the anthropoids. In the lower jaw the second premolar has two roots, and in the upper jaw the first and the second both have three. In *Pithecanthropus* the lower premolar in question is single-rooted, the first upper has three and the second two roots. In modern man two roots in the second lower premolar are extremely rare (one case was observed among 2,089 specimens), while three separate roots occur in the first upper premolar in 3 per cent, three roots in the second in only 0.3 per cent, two in 3.5 per cent of specimens¹².

In the relative size of the molars, the increase in size from the first to the last lower molar, and in the upper jaw the second molar being larger than the first, *Pithecanthropus* shows the same primitive conditions as the Australopithecinae and the anthropoids. There is, however, a tendency for the last upper molar in *Paranthropus crassidens* to be enlarged; this is not found either in the Hominidae (in modern man this molar is often completely reduced) or in the anthropoids.

The deciduous dentition is of great value for the determination of the phylogenetic position. In *Sinanthropus* as in *Pithecanthropus modjokertensis* the first lower deciduous molar has two main cusps—as also the chimpanzee and the orang; in the first form the entoconid is absent, as is common in the anthropoids, in the second very faint. Complete absence of the entoconid in modern man is found in about 2 per cent of specimens only. In the Australopithecinae this cusp is not only developed to the same degree as in modern man (in *Australopithecus africanus* this point is not so clear), but there is also a tendency towards a complete molarization of this tooth, which reaches a maximum in *Plesianthropus transvaalensis* for the upper and in *Paranthropus robustus* for the lower molar; in the latter form, except for its size, this tooth is indistinguishable from the second deciduous molar. There is a certain amount of variability in modern man; but extreme conditions like these have not been observed in a vast collection of modern teeth at our disposal (Bolk Collection, Amsterdam).

This comparison already reveals so many features which must be regarded as a sign of over-specialization that they exclude the Australopithecinae from the ancestorship not only of *Pithecanthropus* but also of *Homo sapiens*.

A greater resemblance exists between the Australopithecinae and the imperfectly known *Meganthropus* from Java; so much so that recently Robinson has included the Javanese species in the same group³. He shows that, especially in the formation of the symphysis, there is a very great resemblance, and he mentions the occurrence of a mental spine in a certain specimen of *Paranthropus crassidens*. We are looking forward with great interest to his final publication.

There are, however, some differences, in which *Meganthropus* is more primitive. There is the basic pattern of the premolars and the first molar, which still have an undivided ridge between protoconid and metaconid, conditions which I could not detect in any of the South African species. The same is true of the presence of a paraconid on the second lower deciduous molar. The first lower premolar is of a more oval outline in the Australopithecinae, whereas in *Meganthropus* it is more angular, as in *Sinanthropus* and Heidelberg man.

The dental arch is probably very similar in both forms, as is evident from a new find, discovered last year¹². This specimen, however, is crushed, and therefore not reliable.

There is not a single feature in the original *Meganthropus* jaw fragment which cannot be matched with other primitive human jaws. In the corresponding part of the *Australopithecus* mandible the two-rooted second premolar must already be regarded as a sign that it belongs to a different category. In fossil human jaws this condition has never been observed; in modern man it occurs in less than 0.02 per cent of specimens. When more is known of *Meganthropus*,

it will probably be found that there are more differences of significance.

However, there can be no doubt that *Meganthropus* and the Australopithecinae have a common ancestor. Such a form must have still had the 'simian gap'—wide *Pithecanthropus*—relatively large canines and incisors, large first lower premolars, and a primitive deciduous dentition. Therefore, it will not fall into the group of the Australopithecinae *s. str.*, and for that reason I cannot agree with Robinson, who claims that the Australopithecinae are "ancestral to the euhominid group" (see ref. 2, p. 37).

Table 1. MESIODISTAL LENGTH OF THE THREE LOWER MOLARS

Lower Pleistocene:	<i>Meganthropus</i>	44.0 mm.
	<i>Pithecanthropus modjokertensis</i>	39.5 mm.
Middle Pleistocene:	<i>Sinanthropus pekinesis</i> (G)	37.7 mm.
	<i>Homo heidelbergensis</i>	36.5 mm.
Upper Pleistocene:	<i>Homo neanderthalensis</i> (Spy II)	34.0 mm.
Recent:	<i>Homo sapiens</i> (White, average)	32.5 mm.

Within this latter group there is a very strong tendency towards a reduction of the dentition, and parallel with it an exaggerated increase in brain capacity (Table 1). The same mesiodistal lengths are for *Plesianthropus transvaalensis* 44.0 mm., and for *Paranthropus crassidens* (average) no less than 48.4 mm., respectively.

Also in regard to the brain capacity the conditions seem fundamentally different. The capacity of the Australopithecinae is a controversial question; Broom gives estimates up to more than 1,000 c.c.¹⁴, and Schepers even calculates "cephalization coefficients" (see Schepers, ref. 14). Let us not forget that only a single skull can be measured, *Plesianthropus V*, and that here the capacity is only 482 c.c.

Most probably in their absolute brain capacity the Australopithecinae bridge the gap which exists between the largest brain of the anthropoids (gorilla with 585 c.c.) and the smallest of the Hominidae (*Pithecanthropus erectus* II with 775 c.c.). There is, however, this important difference: the greatest brain capacity in the Australopithecinae goes together with the largest molars, whereas in man it goes with the smallest molars. We have tried to express this relation in a brain-molar coefficient¹⁵—brain capacity in cubic centimetres divided by the mesiodistal length of the three upper molars in millimetres, both measurements taken on the same skull—the results of which are given in Table 2.

Table 2. BRAIN-MOLAR COEFFICIENTS

(The numbers in brackets indicate the number of skulls measured)		
Chimpanzee (7)	10.9-13.9	average: 11.8
Orang (16)	9.8-12.4	10.9
Gorilla (10)	9.0-13.0	11.7
<i>Plesianthropus V</i>	13.4	
<i>Pithecanthropus modjokertensis</i>	25.8	
<i>Pithecanthropus erectus</i>	24.3	
<i>Sinanthropus pekinesis</i> XI	34.2	
<i>Homo neanderthalensis</i> (Steinheim)	36.7	
<i>Homo sapiens</i> (Europeans, 10)	23.5-37.1	47.8

As we expected, the modern anthropoids form a homogeneous group. The values for *Pithecanthropus* are estimates: a capacity of 1,000 c.c. was estimated by Weidenreich for the skull of *modjokertensis*, and for *erectus* we have used a dentition, not yet described, from a different individual. In Table 2 the anthropoids are sharply separated from the Hominidae; *Plesianthropus* is not intermediate, since it comes within the range of the anthropoids.

This coefficient has still another advantage. If we take a maximum of about 15 for the anthropoids, then the Australopithecinae with their large molars will still remain within the anthropoid group, even with a brain capacity of more than 700 c.c.

Two specimens of the large *Plesianthropus* from Swartkrans have a well-developed sagittal crest¹¹, which is not found in the smaller species. Apart from the fact that this must be taken as a sign of a limited brain capacity, it is to be noted that a sagittal crest in the anthropoids depends upon the absolute size of the species. It is absent from the small gibbon, very rare in male chimpanzees, normal in male orangs and practically always present in the male and often in the large female gorillas. That this structure appears among the Australopithecinae under the same conditions is a very important parallel to the anthropoids, and a significant difference from the Hominidae.

Thus the Australopithecinae apparently are a group of the Hominidae, which most probably did not rise much above the 'anthropoid' level. The reduction of the dentition only affects the face; their increase in brain capacity is slight and depends upon the absolute size of the species; the possession of a sagittal crest in the large specimen parallels the development of the same structure in the anthropoids. It seems that towards the end of the Pliocene period the early Hominidae were separated into several branches—Australopithecinae in Africa, *Gigantopithecus* (and undescribed forms) in China, Pithecanthropi in Asia—and that only one of them, the Pithecanthropi, by a harmonious reduction of the whole dentition and—this is the most important point—by an exaggerated and accelerated increase of the brain capacity, gave rise to the Hominidae, of which group we are the most human members.

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

REPORT FOR THE YEAR 1952-53

THE report of the Department of Scientific and Industrial Research for the year 1952-53* follows the accepted pattern of previous years. Now exceeding three hundred pages, it includes the short report of the Committee of the Privy Council, over Lord Salisbury's signature, and the thirty-eighth annual report of the Advisory Council, signed by Sir Ian Heilbron, together with the usual summary of work carried out by the various research stations and boards and research associations. The appendices include a thirty-seven page classified list of departmental publications issued during the year and the

usual lists of assessors to the Advisory Council, of members of the research boards of the Department, and of grants for special investigations during the year. With the lists of the Department's establishments and of the research associations, it provides the scientific and industrial world with material for a sound judgment as to the worth of the Department's work, though the average member of Parliament may well be glad of some further guidance from the Parliamentary and Scientific Committee in assessing the value which the nation is getting for an expenditure of £5,773,803 gross during the year ended March 31, 1953.

This figure compares with £5,452,165 in the previous year and was reduced to £5,207,455 by various receipts (mainly by the National Physical Laboratory) for work done for other Government departments or for industry, the net increase on 1951-52 being £250,636. On October 1, 1953, the Department employed 4,078 staff of all grades (including 159 part-time), compared with 4,035 (149 part-time) the previous year. Annual grants to research associations, totalling £1,449,635, with special grants of £16,804, were as usual the largest single item of expenditure, followed by that of £860,842 gross, or £546,617 net, on the National Physical Laboratory. Grants for special researches remained at about the same level, £317,321, compared with £313,693 during 1951-52. Most of those listed are spread over a period of years, the largest, apart from the £230,000 for radio-astronomy at the University of Manchester, being £617,500 for the construction of a 400-MeV. proton synchro-cyclotron and other high-energy equipment for nuclear physics research at the University of Liverpool, £354,700 for the construction of a 300-MeV. electron synchrotron and other high-energy equipment for nuclear physics research at the University of Glasgow, £231,500 for the construction of a 1,000-MeV. proton synchrotron and experimental work with a 60-in. cyclotron at the University of Birmingham, £191,000 for the construction of a 140-MeV. electron synchrotron and other equipment for nuclear physics research at the University of Oxford, and £160,000 for construction of a 300-400 MeV. linear electron accelerator at the University of Cambridge. Besides this, grants amounting to as much as £209,500 (University of Liverpool) have been made for running expenditure on nuclear physics research. These grants for running expenditure, which total more than £800,000, extend for five years from August 1, 1952; and by the end of that period the Advisory Council expects these heavy financial responsibilities for nuclear research in the universities to be terminated so as to bring its net annual resources for general purposes to something of the order of six million pounds.

Grants to students amounted to £265,897 net, an increase of £14,856, the number of students in training being 976, compared with 923 during 1951-52, and 413 of these were new. Senior research awards numbered fourteen, seven of which were new, compared with thirteen during 1951-52, and forty-one new grants for special investigations brought the total of such grants to seventy, compared with ninety-one during 1951-52. Of the senior research awards, eight were in physics and three each in chemistry and in engineering; and of the grants for special investigations, thirty-two were in physics, twenty in chemistry, and six each in biology and in engineering. Chemistry claimed 419 and physics 283 of the grants to students; 79 were in engineering,

* Department of Scientific and Industrial Research. Report for the Year 1952-53 (Cmd. 9063). Pp. 315. (London: H.M.S.O., 1954.) 5s. net.

78 in biology, 50 in mathematics and astronomy, 41 in geology and mineralogy, and 26 in metallurgy.

With the exception of building research, expenditure on which decreased by £77,190 to £420,933 net, and on the National Physical Laboratory, which showed a net decrease of £12,718, expenditure on all sections of the work increased, although net expenditure on water pollution research (£61,424), fire research (£28,344), hydraulics (£57,676), pest infestation (£56,636), forest products research (£106,114) and on the Geological Survey and Museum (£206,131) was no more than up to 10 per cent higher than during 1951-52. The larger increases of £17,051 on the Chemical Research Laboratory (to £118,574 net), of £18,538 on fuel research (to £237,692) and of £19,506 on road research (to £292,965) fell well within the same order of magnitude. Only the increases of £27,703 on radio research (to £50,719), of £34,502 on food investigation (to £220,531) and of £78,733 on mechanical engineering, represent more significant increases in the scale of operations.

At a total of £346,157, net expenditure on mechanical engineering ranks fourth in the net outgoings of the Department, and it is now expected that the essential building programme will be completed by 1959 at a cost of about £2 million. More than £500,000 has now been expended on the purchase of the site and on buildings at East Kilbride for the Mechanical Engineering Research Organization, and a staff of more than 250 was built up towards the total of 500-700 contemplated in the original proposals for the Organization. The Advisory Council comments on the much more favourable prospects for the expansion of this Organization during the five years commencing April 1, 1954, under the new arrangements announced in November last, particularly in view of the greater flexibility given by the provision that surplus funds due to underspending in any one year may be carried over to subsequent years. Apart from this, provision has been made for small increases of staff and of expenditure on new buildings during the current financial year both at East Kilbride and for the Hydraulics Research Station at Wallingford. At the latter station some three-quarters of the staff originally contemplated have now been recruited, largely within the past year, and by early 1955 some £500,000 will have been expended on the purchase of the site and provision of buildings. A good beginning has already been made with a substantial programme of research, including experimental studies with models of river estuaries and harbours, theoretical studies of the movement of materials by the action of waves, coast erosion, and the development of instruments. In a study of the changes in the bed of Morecambe Bay, made at the request of the Railway Executive and completed during the year, the Station was able to show that the changes occur cyclically and that the present deterioration of the channel to Heysham Harbour would not be permanent. Progress has also been made in developing research techniques for the study of coastal erosion; a pneumatic tide-generator for use in models has been developed; and the Advisory Council was satisfied on its visit to the Station that important contributions to this branch of civil engineering are already being made there.

The two other establishments of the Department which were formally visited by the Advisory Council during the year were the National Physical Laboratory and the Chemical Research Laboratory, both

of which are at Teddington. The former is by far the largest of the establishments and is also the most diverse in its activities, although work is continually being transferred from the Laboratory to form the basis of new institutions. The Advisory Council, emphasizing the dynamic character of the National Physical Laboratory's organization, points out that much of its work is undertaken to serve the basic needs of industry in general and of the public. Its work on the maintenance of increasingly accurate standards of measurement, although only a small part of the Laboratory's work, remains of fundamental importance, and measurements of the speed of light or the development of a new method of producing diffraction gratings are no longer of purely academic interest but of fundamental importance in both science and industry. Theoretical studies and small-scale experiments in wind tunnels by the Aerodynamics Division of the Laboratory are assisting to define the nature of the problems of the behaviour of bodies moving in air at speeds greater than that of sound, which confront the designer of aircraft; and in the theoretical studies of high-speed flight, and in a wide range of other investigations, the Automatic Computing Engine, designed and built at the Laboratory with the help of industry, is assisting to solve mathematical problems of great complexity.

The Advisory Council's visit equally convinced it of the importance of the work of the Chemical Research Laboratory. It was particularly impressed by the work of the new radiochemical laboratory on the analysis and concentration of radioactive materials, and the importance of microbiological work of the Laboratory is also stressed in the report. The work of this Laboratory has recently been reviewed in these columns (*Nature*, 172, 664 and 832; 1953), and no more need here be added than that the Advisory Council directs attention to the economic value of the work on the corrosion of metals and the recovery of valuable constituents from waste materials or low-grade sources.

From the account of the work of the other establishments of the Department, which occupies some eighty-nine pages of the summary of work, compared with a hundred and thirteen devoted to the work of the research associations, only a few examples of the range and importance of the contribution being made to the national welfare and economy can be selected. During the past year the Joint Fire Research Organization has been able for the first time to examine statistics covering a period of five years and thus to examine trends in certain types of hazard, with the result that steps have already been taken to eliminate or mitigate the worst hazards to which some new types of post-war houses appear to be prone. Considerable progress has been made in the study of smouldering in industrial dusts and other materials such as jute sacking and fibre insulating boards, and fresh light has been thrown by a model technique on the importance of ventilation, in the development and control of fires. Commenting on the first five years of work of the Organization, the Advisory Council expresses the view that the experiment has been completely satisfactory.

The Building Research Station continued its study of productivity, including an investigation at Norwich of the potential value of a rail-mounted tower crane in house-building, which has led to the development of several special pieces of equipment for handling various building materials and to the design of special equipment, such as turntables, to enable the

crane to negotiate corners. In collaboration with the Forest Products Research Laboratory, the Station has shown in laboratory tests and in small-scale trials that a zinc oxychloride paint or plaster effectively prevents the spread of dry rot. Work on the use of pulverised fuel-ash for brick-making has been pursued on a larger scale in collaboration with the British Electricity Authority; and, besides work on prestressed concrete which has established a correlation between behaviour under static and impact loading and on the stiffening effects of walls and floors on structural frameworks, the Station has investigated the soil mechanics of serious breaches in the earth banks of the sea defences in Kent and Essex. The Station has also closely co-operated with the Architects Branch of the Ministry of Education in experimental work on the heating, lighting and acoustics of schools, which has indicated possibilities of economy in fuel by warm-air heating, and a survey of the design and performance of drainage systems is being made with the object of making recommendations for economical and efficient practice.

Under the Food Investigation Organization, wastage surveys have confirmed that the washing of eggs on the farm adversely affects the storage life of the egg. At the Torry Research Station a pilot-scale vertical-plate freezer has been designed which may be suitable for installation on existing vessels, and experiments have indicated that fish can be held in ice for at least three days before freezing without detriment to quality. To meet the needs of the Humber area, a new laboratory was opened in December 1952 as an outstation of the Torry Research Station. A mobile refrigerated store has been designed and built which has been used in various producing areas in England and Scotland for precooling strawberries, raspberries and plums immediately after harvest, to improve the keeping qualities, and for storing Cornish broccoli and spring cabbage; and means of reducing the costs of the two main methods of suppressing the sprouting of stored potatoes are being investigated, for both the use of growth-inhibiting vapours, such as amyl alcohol, and cool storage, are still too expensive. Basic investigations include studies of the properties of the proteins of connective tissue and of the fibrous protein, as it exists in tissues, of the lipids, proteins and soluble extractives of fish flesh, of the chemistry of wood smoke and of the chemical substances which are responsible for the browning, caused by certain enzymes, which occurs when some living plant tissues are injured. The volatile substances produced by apples during storage are being identified and estimated, and a survey is being made of the ascorbic acid content of the chief herbage plants.

In the Forest Products Research Laboratory high priority has been given to the production of preservative-treated plywood. New projects in timber mechanics include investigations on the strength of struts of the type used in light constructional work; on the effect of the construction of plywoods on their strength; and on the design, performance and working stresses of plywood components in structures. General biological work on the common furniture beetle, and further work on the production of hardboards from tropical timbers continued, while studies of beech, oak and Corsican pine showed that at a given humidity the Young's moduli decrease linearly with increase of temperature, although at 90 per cent relative humidity there is evidence of a curvilinear relation.

Increased calls for advisory work continued to be made on the Fuel Research Station, which is exploring the possibility of a relation between the rank of a coal and the germanium content as part of a survey of the occurrence of germanium. Work on the production of metallurgical coke by carbonizing blends of coking coals with other coals continued, and also the study of the factors responsible for changes in the flow properties of residual fuel oils during storage. Work has been started on the adsorption of argon at low temperatures on the iron catalysts used for the Fischer-Tropsch synthesis to see if there is any relation between pore structure and catalytic activity. Efficiencies of up to 90 per cent have been obtained in the removal of sulphur dioxide from flue gas in a scrubber containing a carbon packing in which the grid surfaces are thoroughly wetted at low rates of liquor circulation and the liquor is aerated through a ceramic filter-candle; further work was also carried out with three types of combustion chamber intended to permit the use of solid fuel in industrial gas-turbines. Work at the Station has shown that emission of smoke from forced-draught or natural-draught hand-fired steam boilers can be prevented by the correct use of secondary air, and for the natural-draught types a special fire door has been developed for the purposes.

The publication of maps and memoirs by the Geological Survey has been retarded by the current necessity for concentrating on problems connected with coalfield development, mineral and water resources and hydro-electric schemes; but some progress has been made in acquiring new basic geological data and applying new methods of research. Field work included a survey of the causes and results of erosion in the valleys converging on Lynmouth in North Devon, and the drilling of a borehole on the advice of the Survey averted the necessity for an expensive scheme of piped water supply to Holy Island; in the search for uranium, field investigations of ore deposits were undertaken by officers of the Atomic Energy Division of the Survey in most of the British Colonies, some Commonwealth countries and other territories overseas. A survey of water resources in areas of Bunter Sandstone in Nottinghamshire showed that, in the northern part of the county, reserves will permit a further daily abstraction of about 19 million gallons, and areas of saline water infiltration in chalk areas in Yorkshire and East Lincolnshire have been similarly defined.

In mechanical engineering research the year has been one of consolidation; but the report refers to the work on the fatigue strength of notched and unnotched high-strength aluminium alloys which is nearing completion and to the installation of laboratory equipment for work on materials subjected to high temperature and complex stresses. Experiments on pitot-tubes in water have established that flutter at higher speeds affects the tube coefficient, but can be virtually eliminated by use of a supporting strut with an aerofoil instead of circular section. Two closed-circuit research rigs have been designed for investigating flow conditions in centrifugal and axial flow pumps up to 25 h.p., and a critical analysis of existing formulae used for scaling-up the performance of model water-turbines has indicated that Reynolds-number corrections should be applied to only part of the losses. A comprehensive programme of research on lubrication and wear had particular reference to the operation of bearings at higher speeds and the elucidation of fundamental aspects of the wear

process. Re-calibration of precision measuring equipment transferred from the National Physical Laboratory was completed during the year, and a new portable instrument for measuring profile errors on large marine gears was completed and used on several sets of gears for the Admiralty. Work on the design and development of the prototype apparatus for torque and vibration measurements on small high-speed precision ball-bearings was nearing completion. The properties and behaviour of materials under hydrostatic pressure were also being investigated, while, besides a survey of literature on heat transfer during 1948-50 which was being published, further surveys are planned, as well as a detailed survey of all data on natural convection from vertical surfaces.

The Pest Infestation Laboratory completed its biological studies on the spider beetle, *Ptinus lectus*, and its investigation of the fauna of dry birds' nests, which indicated that old nests built on or inside houses constitute a frequent point of entry for such pests as the carpet beetle. A detailed investigation of the storage of grain under air-tight conditions was in progress, and recommendations, based on experimental work, for a twice-weekly application of 5 per cent DDT dust gave virtually complete control of emergence of blowflies from refuse when adopted by the borough council concerned. The effect of insecticides and fumigants on the carbohydrate metabolism of insects was being studied, and a modified method of paper chromatography was developed for the micro-analysis of mixtures of pyrethrins and their derivatives.

The main contribution of the Radio Research Organization is in the field of wave-propagation, where its investigations have led to a better understanding of the mechanisms of transmission between transmitter and receiver and of the properties of the medium traversed. Ionospheric investigations have included the study of propagation conditions over routes extending to many thousands of kilometres and hourly measurements of ionospheric conditions at seven observatories distributed over the world, while the data accruing from the study of high-frequency noise during 1945-51 have been reviewed in a special report. The Station is also concerned with the properties of materials of importance in the technique of telecommunications. The new Water Pollution Research Laboratory at Stevenage, Herts, is expected to be ready for occupation by the middle of 1954, when the work at present carried out at Watford, Garston, Birmingham and Coventry will be transferred to the new building. The Advisory Council stresses the growing importance of the work on water pollution, and instances the anxiety caused by the condition of the Thames Estuary, to the study of which the Laboratory is at present devoting much of its resources. Other work has been concerned with the effects of customary processes of water treatment on the removal from water of small quantities of radioactive substances, particularly those used in medicine and industry, the treatment of sewage by the process of alternating double filtration, the anaerobic fermentation of liquor from the kieren of cotton, the effects of cyanides on the treatment of sewage in percolating filters, and the development of a standard method for assaying the toxicity of industrial wastes to fish. The work of the Intelligence and Information Division, to which special attention was directed by the Advisory Council in last year's report, receives this year a

special section in the "Summary of Work", stress being laid on the work on the conservation of raw materials and the development of programmes of research on human factors in industry, production economics and industrial engineering.

New or revised terms of grant were offered to seven research associations during the year, as well as to the Research Committee of the Furniture Development Council, and the British Whiting Federation Research Council, while the Commonwealth Mycological Institute is to receive £1,000 a year for the five-year period from April 1, 1953, for the maintenance and expansion of its collection of fungi of industrial importance until the appointment of an additional mycologist, and thereafter £2,000 a year. The British Cast Iron Research Association receives a further block grant of £20,000 for the period July 1, 1953-June 30, 1954, and an additional £100 for each £100 from industry on the same terms as for the previous five years. Its work on the influence of gaseous elements in cast iron continues to increase: a theoretical study of factors influencing the oxygen content has been completed and work commenced on both oxygen and hydrogen. A comprehensive account has been prepared of the effects of composition and structure on electrical resistivity, and progress made in improving methods of sampling and analysis. Negotiations were in progress for the manufacture of the extractor unit specially designed to control respirable dust from pedestal grinding wheels, and work on the protection of marine propellers from corrosion and also of water mains buried in corrosive soils has reached the development stage.

For the period January 1, 1953-December 31, 1957, the British Ceramic Research Association, which now covers all the activities of the ceramic industry, is to receive a block grant of £30,000 a year, conditional on £80,000 from the industry, and an additional £100 for each £100 from industry up to a maximum of £20,000. A major task of the Association continues to be the definition and control of the properties of the raw materials used in the pottery industry, and attempts are being made at the direct determination of the constituent elements in a clay. The principles involved in a satisfactory system of controlling the rheological properties of the slip have been worked out and put into operation in several works, and much attention has been given to the study of chrome-magnesite and magnesite-chrome bricks for steel furnaces. In long-term work on the design and operation of a homogeneous extruded column, a device has been developed for controlling the moisture content of the clay by means of a valve operated by the thrust on the screw, and this device has proved satisfactory in works trials. For the British Coal Utilization Research Association a block grant of £45,000 a year was made for the period January 1, 1953-December 31, 1957, conditional on £190,000 from industry, and a further £50 for each additional £100 from industry up to a maximum of £30,000. Early in the year the new laboratories for work on domestic appliances were opened, and here an electrostatic precipitator has been developed through which the whole flow of flue gas can be passed without appreciable drop and which deposits all smoke on light concentric cylinders where it can be weighed. Work on cyclone combustion has aimed at discovering principles of design for a combustion chamber of suitably limited size to operate under pressure with a gas turbine. Investigations on the effects of coal properties on boiler

performance, using a chain-grate stoker, have been completed, and work on gas producers has endeavoured to ameliorate tar deposition and improve the quality of gas.

The new block grant for the British Gelatine and Glue Research Association for 1953-55 is at the rate of £6,000 a year, conditional on £8,000 from industry, with a further £100 for each £100 from industry up to a maximum of £4,000. The Association, the laboratories of which have only been operating during the past three years, has developed a new technique for fractionating gelatin, based on the solubility in aqueous sodium chloride solution of the complex formed between dodecyl sodium sulphate and gelatin, while an instrument has been designed and produced to check the performance of the testing machine used to grade gelatine and glue as gelling agents. The British Hydromechanics Research Association, the laboratory of which at Harlow was only opened in 1951, is concerned with four main fields of work: general problems in fluid flow; centrifugal and allied pumps and turbines; positive displacement machinery; and seals and glands. Useful work on the hydraulic transport of solids and on the design of pump suction pumps has already been carried out, and for the period October 1, 1953-September 30, 1958, the block grant is £9,000 a year, conditional on £18,000 from industry, with a further £75 for each £100 from industry up to a maximum of £9,000.

The research programme of the British Scientific Instrument Research Association has been drastically pruned. Marked progress is reported in the work on anti-glare glass for instrument windows, the use of digital machines in optical computing, the thickness measurement of metal sheets, humidity-sensitive ceramic elements and the conditions governing the efficient use of diamond-bonded tools. For the period April 1, 1955-March 31, 1958, the block grant will continue at £35,000 a year, conditional on £17,500 from industry, with a further £100 for each £100 from industry up to a maximum of £15,000. The new block grant to the Coal Tar Research Association for the period April 1, 1953-March 31, 1958, will also continue at the present rate of £12,000 a year, but conditional on £45,000 from industry, with an additional £50 for each £100 from industry up to a maximum of £12,000. Current work has included the study of the chemical and physical nature of tar and pitch, the utilization of pitch and of creosote, and service work on such problems as the corrosion of mild-steel distilling equipment by hot tar and tar oils, or the formation of deposits in tar stills. Studies on the chemical composition of a pitch-cooking distillate, the electrophoresis and ultra-centrifuging of tars and solutions of pitch were in progress, and the low-temperature non-destructive hydrogenation of tar oils has been extended to the production of tetrahydronaphthalene and *trans*-decahydronaphthalene from crude and refined naphthalene, and the removal of sulphur from anthracene and phenanthrene.

Besides these grants, two special grants were made towards heavy capital expenditure. One of them, not exceeding £100,000 and conditional on special contributions of £200,000 from industry, was approved towards the new laboratory at Leatherhead of the British Electrical and Allied Industries Research Association where, besides its main work on the generation of electrical energy, the economical transmission and distribution and the most efficient

utilization of such energy and the reliability of equipment, the Association carries out a substantial amount of fundamental research, in which a general theory of electrons in dielectrics has been established so far as concerns the method of approach; and work on the relation between permittivity, loss angle and structure has shown the importance of texture in determining the properties of a dielectric. In rural electrification, good progress is reported in research on the drying of grain, seeds and fodder crops, and promising results were obtained in preliminary work on the destruction of pests in grain by high-frequency electric fields. The second grant, also not exceeding £100,000 and conditional on not less than £300,000 from industry, was to the British Coke Research Association towards a full-scale oven plant to test the possibilities of producing satisfactory coke from blends of coal, including those individually unsuitable.

During 1952 there were forty-one research associations, with an income of four million pounds, of which £1.3 millions came from the Department, compared with twenty-one research associations with an income of £480,000 (£178,000 grant) during 1939. Of the work of the remaining associations, no more can be said here than brief comments on four associations. The formation of the Rayon Section of the British Cotton Industry Research Association in 1928 has contributed largely to the ability of the industry to deal with the new man-made fibres, and the Association has contributed a considerable number of successful devices to improve output or conditions. The Hosiery and Allied Trades Research Association has devised a practical means for synchronizing the rate of feed of yarn to hosiery knitting machines, and a method of impregnating chrome leather with rubber latex, devised by the British Leather Manufacturers' Research Association, permits leather to be waterproofed without losing its ability to transmit water vapour. The Printing, Packaging and Allied Trades Research Association has been concerned with developing the techniques for measuring and comparing odour with the object of assessing the possibility of odour contamination from materials used in making the packing.

The annual report of the Department thus presents a picture of widely varied activities affecting almost every aspect of industry and national welfare. It is a picture, too, of increasing co-operation and of an organization which is intimately interlocked with the national research effort in Great Britain as a whole, whether concerned with defence, the development of atomic energy or the fundamental research in progress at the universities. The wise direction of this expenditure of effort is a matter of continuing concern to industry and the universities as well as to Parliament, and the present annual report goes far to provide a basis for sound judgment as to the wisdom with which the Department's activities are planned and its objectives selected. The very complexity of the relations disclosed, however, demonstrates the shortsightedness and wastefulness of some of the reductions in expenditure imposed on the Department during recent years. The material supplied in this latest annual report should be used by scientific workers and industrialists to make sure that in future the activities of the Department are guided and modified by views of a sufficiently long range to avoid wasteful repercussions and secure that the nation reaps some return from activities to which it has once been committed.

OBITUARIES

Dr. G. P. Bidder

GEORGE PARKER BIDDER died on December 31, 1953, in his ninety-first year—for many years president of the Marine Biological Association, sometime president of Section D (Zoology) of the British Association, secretary of the Linnean Society during 1928–31 and vice-president in 1924 and 1932, a founder of the Association of British Zoologists, and a distinguished authority on the sponges. He was a man to whom more than one generation of biologists were indebted for counsel and for help. At no time a professional scientist, he was perhaps the last of his kind—that of the great amateur biologists of the past century.

He was the grandson of his namesake, the famous 'calculating boy', and had something of the same remarkable quality of memory. At the first council of the newly formed Society for Experimental Biology in 1923, the secretary disclosed that the blackboard on which was written the constitution had been wiped clean without any record in writing. Dr. Bidder adjourned the meeting for fifteen minutes: he then wrote out from memory the entire constitution; and the secretary then read the minutes.

Bidder had his first taste of biology as a boy at Harrow, a taste confirmed when in 1881 he spent a year under Ray Lankester at University College, London. He then went up to Trinity College, Cambridge. This was just after the tragic death of Francis Maitland Balfour at the height of his power as comparative anatomist and embryologist: as Bidder once said, "a great and exciting laboratory—ruled by a ghost". On leaving Cambridge in 1886 he occupied the University Table at the Stazione Zoologica, at Naples. So began his long association with marine biology.

In 1890 he married Miss Marion Greenwood, a biologist who had already done elegant work on the physiology of *Hydra*. Many Cambridge biologists remember with fresh regret her death in 1932. For a few years they lived at Plymouth, while he worked at the Plymouth Laboratory in close touch with Dr. H. J. Allen. They settled in 1902 at Cavendish Corner, Cambridge. Unfortunately, he soon became seriously ill and was a semi-invalid for more than ten years. But he was not a man to be put down by circumstance, and after his illness he returned to assume the active position in biological affairs which he retained for the rest of his long life.

He did this in his own way. By present standards he was unconventional—or it were better to say that he had the patrician ability to make his own system of conventions. Few young biologists to-day would suddenly decide to buy a Neapolitan hotel—'Parker's'—as he did in 1889; and to run it successfully and for some time. Also few to-day could happily and successfully organize a life in which the active day started towards evening, and one did not retire until the early hours of the next morning. But unlike the Watertons and the Frank Bucklands of the past century, he used his freedom from convention and his independent and disinterested position to seize the moment to do things essential for biological advance—things that could not be done by the professional scientist, and which can never be done simply and in time by official bodies. In the early days of the Plymouth Laboratory it was scientifically necessary to buy a vessel for fishery work. There

were official difficulties about doing this. Bidder himself borrowed the money to buy a ship, hired it to the Association for the work, and ultimately arranged for it to be sold at a profit—characteristically using the proceeds to found the Ray Lankester Investigatorship. Such long-sighted and timely action was characteristic of his life. It was action of this sort by him that perhaps more than any other single factor helped the Stazione Zoologica at Naples to survive two world wars and to regain its present great position in international science.

Two major scientific periodicals, the *Quarterly Journal of Microscopical Science* (of which he became for long the owner) and the *Journal of Experimental Biology*, owe their continued existence to his help and wise advice. These were only some of his many-sided activities. He was no narrow specialist, but a man of culture with major interests spreading far outside biology. For many years he was managing director of the Cannock Chase Colliery.

Bidder enjoyed conversation and scientific speculation; but his interest was in real phenomena rather than ideas alone. For that reason, his scientific contributions were not just the elegant speculations of a dilettante, but a real influence on current biological thought; particularly those concerned with the form of organisms. Though, to the regret of many of his friends, he was never elected into the Royal Society, he will, I believe, prove to have been one of the most interesting figures of early twentieth-century science. He was a lasting example of how much good can be done by the individual action of a shrewd, kind, disinterested and able man. More than one generation of biologists learnt from him the value of approaching research, not in a spirit of narrow specialization but in one which is best summed up in a characteristic opening phrase of his own—"It has often occurred to me to wonder . . .".

C. F. A. PANTIN

Mr. S. F. Ashby

SYDNEY FRANCIS ASHBY was born on December 31, 1874, at Rockferry, Cheshire. His father was a gifted artist and his mother the daughter of a naval officer. He studied first at the University of Liverpool, then at Edinburgh, where he graduated. Afterwards he proceeded to the Universities of Halle and Göttingen and spent some time in Denmark studying the bacteriology of water. He returned to England and worked at the Rothamsted Experimental Station as Carnegie Research Fellow under Sir Daniel Hall. While there he was offered the post of microbiologist to the Government of Jamaica, which he accepted in 1906. He married in January 1910 Miss Cork, daughter of Mr. William Cork, supervisor of revenue, and returned to England in June 1910. He studied in London until 1912, when he went back to Jamaica, specifically to see what could be done about the dreaded Panama disease of bananas, caused by the fungus *Fusarium oxysporum* var. *cubense*, which had been introduced into the Island in 1911. He remained in Jamaica until February 1921, when he was appointed professor of mycology at the Imperial College of Tropical Agriculture, Trinidad. He occupied the chair for a little over five years and returned to England in April 1926 as senior mycologist at the then Imperial Bureau of Mycology. On the resignation of the late Sir Edwin Butler in 1935 he was appointed director of the Imperial Mycological Institute, as it was then known. He relinquished this post in 1939 on retire-

ment. Early in the Second World War he suffered the grievous loss of his son, who was killed in his first operational flight as an observer in the Royal Air Force.

Throughout his scientific career Ashby was thorough and reliable in his work. His first research concerned the assimilation of nitrogen by a soil bacterium. In Jamaica he studied banana diseases and within six months published a valuable account of the work in the Bulletin of the Department in 1912, including a section on Panama disease. For the control of the disease he recommended the isolation of all infected areas, the boundary being set one chain distant from the nearest diseased plant. This treatment was immediately successful and no diseased plants were found outside the boundary line seven to nine months after treatment. Every diseased tree within the affected area was cut down, the stool dug up, and the whole burnt. There is no question but that Ashby's prompt and sound action saved the Jamaica banana industry from ruin and allowed the farmer a means of keeping the disease in check. Unhappily, in the course of years farmers became impatient at having to leave so much land out of cultivation and ultimately Ashby's policy had to be moderated and finally abandoned as the disease gradually got out of control. If his method had been consistently followed the progress of Panama disease would have been impeded much more than it actually was; but in any event, the slowing up of the spread of the disease allowed planters valuable time to consider alternative crops. While in Jamaica, Ashby also published in 1920 notes on a disease of coconut caused by *P. palmivora* and another by *P. parasitica*, and in 1921 an account of sugar-cane mosaic.

Throughout his life he maintained his interest in the important genus *Phytophthora*. In 1925 he became interested in *Stilbum flavidum* on coffee and succeeded in isolating and growing the fungus in culture, proving conclusively that the *Stilbum* is a state of the perfect form *Omphalia flavida*. In 1928 he published with W. Nowell a joint study on the fungi of Stigmatomycoses, a classic paper on a peculiar group of fungi attacking cotton bolls, one of which, since named *Erasmiothecium ashbyi*, proved during the War to be a producer of riboflavin. His next important contribution was on bacterial wilt of

bananas, which he showed was due to *Bacterium solanacearum* (Kew Bull., 14; 1927). In 1929 Mr. Ashby visited Dominica in connexion with the outbreak of red rot disease of limes and was able to assure the authorities that the prevalent fungus *Sphaerostilbe repens* had been present in the island since 1911 and was not a virulent pathogen. On his return he concluded an important paper on leaf scald of sugar-cane, naming the causal organism *Bacterium albilineans*. Two papers on *Phytophthora* followed, concerned with the production of sexual organs, and one on *Gloeosporium* strains isolated from bananas. When Mr. Ashby retired in 1939 he had accumulated on behalf of correspondents a vast amount of knowledge about the genus *Phytophthora*; but he did not put this information in print. He died on March 6 after a prolonged period of illness and is survived by his widow and one son. S. P. WILTSHIRE

Mr. J. G. R. Elbo

JOHN GREGGERS ROSENSTAND ELBO died on March 11 at Carlton, near Cambridge, at the early age of thirty-one. He joined the staff of the Scott Polar Research Institute in 1946 as part-time assistant in Scandinavian studies, and specialized in the problems of northern Scandinavia, Svalbard and Greenland. He took his degree in modern languages at Cambridge in 1950, and then decided to study for a research degree in Eskimo philology. Meanwhile, the first sign of serious illness had become evident as early as 1948; despite apparently successful treatment his health slowly deteriorated, until in September 1953 the last illness began.

We regret to announce the following deaths:

Mr. Roland Austin, during 1927-48 joint editor of *Antiquity*, aged seventy-nine years.

Mr. E. Graham Clark, C.B.E., secretary of the Institution of Civil Engineers, a post from which he was due to retire this year (see *Nature*, March 6, p. 427), on April 23, aged sixty-four.

Prof. Methodi Popov, director of the Institute of Biology, University of Sofia, on April 20, aged seventy-three.

NEWS and VIEWS

The Australian Academy of Science

THE Australian Academy of Science was founded in 1952 (*Nature*, 170, 549; 1952); on February 16, H.M. the Queen, during her visit to Australia, presented a Royal Charter to the officers and Council-elect of the Academy. This is the first time in nearly 300 years that a reigning British sovereign has founded a scientific society, the only previous occasion being the founding of the Royal Society of London by Charles II. The names of the Council-elect are announced in the *Australian Journal of Science* for February; these have to be ratified at the first general meeting of the Academy during April 6-7 when twenty-seven new Fellows will be elected. Also to be ratified at the meeting are the nominations of the following officers: *President*, Prof. M. L. Oliphant; *Treasurer*, H. R. Marston; *Secretary (Physical Sciences)*, Dr. D. F. Martyn; *Secretary (Biological Sciences)*, Dr. A. J. Nicholson.

New Zealand Science Review

To commemorate the recent visit of H.M. the Queen and H.R.H. the Duke of Edinburgh, the January issue of the *New Zealand Science Review* is a "Royalty and Science" number (12, 1; 1954). After a brief editorial article welcoming the Royal couple, the address entitled "Science and the Scientific Worker" given by the Duke before New Zealand scientists on January 13 is reported in full. This meeting was organized by the Royal Society of New Zealand, with its president, Dr. W. R. B. Oliver, in the chair. During his speech, the Duke conveyed greetings to the Royal Society of New Zealand from the Royal Society of London and the British Association for the Advancement of Science. Then follows an informative article reviewing the history of the interest shown by royalty in science. I. D. Dick contributes a more specialized article on "Royalty and Science in New Zealand". It was also a happy

thought to include in this number the complete presidential address delivered by the Duke before the British Association meeting in Edinburgh in 1951, for that address is still recalled by many as one of the most forcible speeches made in recent years. Dr. Oliver gives a historical account of the Royal Society of New Zealand, which was founded in 1867 as the New Zealand Institute. In the same issue it is announced that publication of a new series of *N.Z. Science Abstracts* is to begin shortly, and that it is hoped that an abstract will appear within a month of the publication of each paper.

Memorial to Dr. W. G. Duffield at Canberra

A MEMORIAL tablet to the late Dr. W. G. Duffield was unveiled by his daughter Miss Joan Duffield, in St. John's Church of England, Canberra, on January 3. Dr. Duffield was the founder and first director of what is now the Commonwealth Observatory, Mt. Stromlo, Canberra, holding office from 1924 to the date of his early death in 1929 at the age of fifty years. The service was held in the presence of many who had been associated with the early development of Canberra. Lessons were read by the present director and Commonwealth Astronomer, Prof. R. v. d. R. Woolley, and the Right Rev. E. H. Burgmann, Bishop of Canberra and Goulburn, who also dedicated the tablet. Sir Robert Garran, in an address recalling the foundation of the Observatory, referred to the earnestness of purpose with which Dr. Duffield fought for so long and for so hard to realize his life's dream. The tablet, in bronze, displays an engraving of the solar tower telescope at Mt. Stromlo which had been one of Dr. Duffield's major interests.

Botany at Swansea: Prof. Florence Mockeridge

PROF. FLORENCE MOCKERIDGE is retiring at the end of the present session from the chair of biology at the University College of Swansea which she has held since 1921. She was the first holder of the chair and was appointed shortly after the establishment of the College. Naturally she found nothing in existence and she had to lay the very foundations of a Department while simultaneously coping with the demands of teaching. No one who has not had such an experience can readily imagine the sheer hard work involved in such an undertaking, which few of the present generation have had to face and which fewer still will have to face in the future. Our forbears who started scientific teaching in the universities a century ago had none of the complex needs of modern laboratory work to cope with, while students were few and the pace was more leisurely. Prof. Mockeridge devoted her whole energy to the task, which made heavy inroads upon her slender reserves of strength, but she has the unselfish satisfaction of looking back upon a job well done for the benefit of others. She leaves a flourishing organization of well-equipped laboratories, growing numbers of students and an increasing research output.

The Department is primarily botanical with herself as head. Zoology has not hitherto been taken up to full degree standard and was under a zoological lecturer, although Prof. Mockeridge was responsible. Her successor will not have this dual responsibility, as zoology is soon to become independent. Prof. Mockeridge was trained under the late Prof. Bottomley at King's College, London, and did much of the work in investigating the chemistry of his 'auximones', which anticipated the discovery of the

auxins. Always young in heart, she has retained a close interest in and sympathy with the work of younger people and has stimulated the research she could no longer do herself. She has been a kind and generous colleague and a wonderful hostess to her fortunate visitors.

Prof. H. E. Street

DR. H. E. STREET, who succeeds Prof. Mockeridge, was born in 1912. He graduated in 1938 at Nottingham as an external student of the University of London, with first-class honours. His first post was on microbiological control work in industry; meanwhile, he enrolled as an evening research student at Birkbeck College under Dr. F. O. Steward. Upon this foundation Dr. Street has built an impressive amount of research on cell metabolism, distinguished for its thoroughness and its grasp of the fundamental problems of chemical physiology. Since going to Manchester in 1949, Dr. Street has established a vigorous research school and has made his laboratory a centre for the study of metabolism in excised roots. He brings to his new post experience as lecturer in the Universities of Nottingham and Manchester, a wide knowledge of modern techniques in plant physiology, and a store of energy and enthusiasm which will be of great benefit in the programme of development which is about to begin in the biological sciences at University College, Swansea.

Katharine Berkan Judd Awards for Cancer Research

THE Katharine Berkan Judd Awards of the Memorial Center for Cancer and Allied Diseases and its research unit, the Sloan-Kettering Institute, have been made to the following for their outstanding contributions in the field of cancer research: Dr. Everts A. Graham, of the Washington University School of Medicine, St. Louis; Dr. George O. Gey, of the Johns Hopkins University School of Medicine, Baltimore; Dr. L. H. Gray, of the Mount Vernon Hospital, Northwood, Middlesex, England; and Dr. Sidney Farber, of the Harvard Medical School, Boston. Dr. Graham's Award is in recognition of his work in cancer surgery and in medical education; he was the first surgeon to remove an entire lung in the treatment of cancer, the patient being still alive to-day twenty years after the operation, and he was also one of the first to work on a possible relationship between lung cancer and tobacco smoke. Dr. Gey's contributions have been in the field of tissue culture, which is important not only for cancer but also for studies of poliomyelitis and other medical research, and in particular he made the long-term culture of human cancer cells known as the HeLa strain, which has been used as a medium for the growth of the polio virus all over the world. Dr. L. H. Gray is a physicist whose speciality is the investigation of the effect of ionizing radiations in normal and cancer cells and the application of this knowledge to radiation therapy. The complementary side of Dr. Gray's treatment by physical methods is represented by Dr. Farber's work in the field of cancer treatment by chemicals; among Dr. Farber's most notable achievements have been his demonstrations that certain chemicals can preferentially damage the cells of certain types of acute leukaemia in children, and this has opened a new field in cancer chemotherapy. The Awards are given in memory of Katharine Berkan Judd, who left a portion of her estate to the Memorial Center for recognition of achievements in the field of cancer, and the recipients, who by

tradition are members of other institutions, are selected by the Sloan-Kettering Division of Cornell University Medical College, the executive faculty of the Memorial Center.

Gulmarg Research Observatory, Kashmir

THE Universities of Aligarh and of Jammu and Kashmir have jointly established a high-altitude research station at Gulmarg in Kashmir, to be known as the Gulmarg Research Observatory, and the Observatory was officially declared open on April 4 by Prof. A. H. Compton, chancellor of Washington University. The Observatory, which is under the direction of Prof. P. S. Gill, head of the Department of Physics, Aligarh, is at a height of 9,000 ft., which, as Prof. Compton pointed out, compares favourably with other high-altitude laboratories such as Mexico City (7,500 ft. and about the same magnetic latitude), Huanacayo, Peru (10,500 ft.), Echo Lake, Colorado (10,000 ft.) and Jungfraujoch, Switzerland (11,800 ft.). Work at higher altitudes is also possible at Khillan Marg (11,000 ft.), which is one hour distant, and at Apharvat (14,000 ft.), which is three hours distant. Prof. Compton, who was the first to initiate cosmic-ray studies in India when he carried out cosmic-ray measurements at Tosh Maidan, Kashmir, in 1928, continued: "The latitude and longitude are of special significance in cosmic-ray measurements, in comparing results with those obtained elsewhere. The latitude is that at which most rapid cosmic-ray changes occur with changing latitude. The longitude is close to that where maximum effects of the earth's magnetic field are felt. Comparison of results found here with those from other stations are thus of special significance with regard to the effects of the earth's magnetic field on the primary cosmic rays, a subject of major theoretical interest".

Suffolk Naturalists' Society: Schools Supplement to Transactions

THE encouragement of younger people in field natural history and practical biology should not be left entirely to the schools, especially since most observational work and recording has to be done at nearly all times of the year and out of school hours. Apart from this, there are certain institutions, especially local natural history societies, which can obviously offer keen enthusiasts special local information and other facilities which are not to be found elsewhere. Some natural history societies do much to encourage young people by inviting them to meetings and organizing excursions. The Suffolk Naturalists' Society has already done much in this connexion by establishing contact with the local schools and making them members; and now it has taken an even more effective step by publishing for the first time a Schools Supplement to its own *Transactions* (8, Part 3; 1953). The Supplement is intended to be a Schools' Natural History Societies' Journal, in which can be published observations and notes received from member schools—together with suggestions of simple work which schools or young naturalists may undertake. In this first issue is a very practical article on "Field Work on Hedges", giving an easily read account of the plant and animal ecology of hedges. This is followed by an article on "Mice and Voles", which not only informs but is also calculated to inspire and stimulate interest. Two shorter articles follow, on "Moles on Flooded Land" and "The Geology of Suffolk" (Part 2). Practical instructions are then given on how to use a micro-

scope for explaining everyday experiences (in this case, why a nettle-leaf stings). Birds naturally loom large in the field naturalists' interest, so a short article on "Bird Identification in the Field" will prove very useful. There are two reports of biological work by young people: (1) "Investigations into Pellets of the Short-eared Owl" by John Petford; (2) "A Weed Study" carried out by Form IIB of Halesworth Area School.

This is an excellent journal from all points of view and will undoubtedly do much to encourage the development of interest in natural history in Suffolk and, it is hoped, well beyond the borders of the county. It is to be published twice a year. Further information concerning the objectives of the Suffolk Naturalists' Society and the Schools' Supplement to its *Transactions* can be obtained from the Earl of Cranbrook, Great Glenham House, Saxmundham, Suffolk.

"Standardized Plant Names" in Australia

THE booklet bearing this title is the revised version of a list, originally published in 1942, of standard common names for the more important Australian grasses, other pasture plants and weeds (Bull. No. 272, Commonwealth Scientific and Industrial Research Organization, Melbourne, Australia, 1953; n.p.). This new index, which runs to some 132 pages, is a thorough revision of the earlier work, the information having been drawn from all the many reliable sources available. The approved botanical name, its synonyms and the standard common names for each species are given in two lists which permit of simple cross-reference.

Veterinaria Italiana

THE first number of *Veterinaria Italiana*, a review of animal hygiene, prophylaxis and therapy, edited by the General Directorate of Italian Veterinary Services with Prof. Giuseppe Caporale as responsible editor, is an attractively produced journal, issued from the Experimental Zooprophyllastic Institute, Teramo (No. 1, January 1954; obtainable from the Institute at c.o. postale N. 20/988; no price). It is a monthly journal containing scientific and practical articles, together with news of veterinary medicine in Italy and the rest of the world. It is intended that the original articles shall have summaries in English, French and German; but in the first issue some articles are in Italian only. This first number is divided into a scientific and a practical part. In the scientific part Dr. L. Badiali writes on the use of isonicotinic acid hydrazide for the prophylaxis of bovine tuberculosis; Dr. A. Mantovini on the culture of canine distemper virus on the chorio-allantoic membranes of eggs; Prof. V. Cilli on animal diseases transmissible to man; and Dr. G. Guarini on the complement deviation reaction for the diagnosis of infective anaemia of the horse. The practical part of the journal contains notes on the therapy of a number of diseases, and the number is completed by reviews of books, abstracts of current veterinary literature and veterinary news. Veterinarians and others interested in the remarkable recent advances in veterinary science will watch the progress of this new journal with interest.

Geographical Studies

WITH the geographical staffs in United Kingdom universities now almost double their pre-war numbers,

and with the publication space of most geographical and closely related journals almost halved as a result of war-time restrictions and rising costs, the emergence of a new journal to cope with the increasing flow of research material now available is not surprising. *Geographical Studies* has been founded very largely by younger geographers to meet this need. The first number, running to some forty thousand words, is well produced apart from an over-reduction of some of the maps and diagrams: it includes research articles from six contributors ranging over a wide field, and also contains notes of geographical interest. Prof. F. K. Hare deals with the boreal conifer zone, while Prof. P. R. Crowe attempts, in an article on the effectiveness of precipitation, a graphical analysis of Thorntwaite's climatic classifications. Dr. G. J. Butland describes the changing land occupancy in southern Chile, and Dr. W. R. Mead, in an article on the language of place, draws some interesting conclusions from a study of two Finnish dictionaries. Geomorphology is represented in an ingenious article from Miss Alice Coleman on the use of the height-range diagram in morphological analysis, and in conclusion J. H. Hubbard contributes some new data on the rainfall of the Gold Coast. It is proposed to issue *Geographical Studies* at least once and possibly twice a year initially. The journal is published from Birkbeck College, Malet Street, London, W.C.1 (price 10s.), and inquiries should be addressed there to Dr. G. H. Dury.

British Mathematical Colloquium

THE sixth British Mathematical Colloquium was held at Cambridge during April 6-8. Among the hundred and seventy members were Prof. A. Zygmund, at present working in Cambridge, and Prof. L. Schwartz, of Paris, who attended as foreign guest of honour. The first day was devoted to algebra, and the following papers were read: Dr. D. Rees, an aspect of multiplicative ideal theory; Dr. W. Ledermann, some recent work on group characters; Mrs. H. Neumann, Hopf's problem; Dr. C. H. Dowker, dimension of metric spaces. The day devoted to analysis included papers by Prof. Zygmund on Hilbert's transform and its generalizations, Mrs. D. Stone on measure algebras, Dr. H. G. Eggleston on extremal geometrical problems, and Prof. Schwartz on distributions and applications to partial differential equations of hyperbolic type. The geometry (third day) discussed was chiefly algebraic: Prof. J. G. Semple, on enumerative geometry and the method of degenerate collineations; Dr. D. B. Scott, on self-correspondences on algebraic curves and surfaces; Dr. J. A. Todd, on canonical systems on algebraic varieties; Prof. D. G. Northcott, on some local and global aspects of the foundations of geometry. The 'splinter groups' worked with enthusiasm during the intervals available from the main programme, and exchanged much information on problems now being actively investigated. On the afternoon of April 7, a visit was paid to the University Mathematical Laboratory. It is hoped to hold a seventh colloquium in 1955, at the University College of the South-West, Exeter.

Wittgenstein's Philosophical Views

In January 1929, Prof. Ludwig Wittgenstein returned to Cambridge after an absence of more than fifteen years. His return was largely due to the influence of Prof. F. P. Ramsey, who described him

as "a philosophic genius of a different order from anyone else I know". Wittgenstein began lecturing in 1930 and continued until 1933. Records of the lectures and subsequent discussions were kept by Prof. G. E. Moore, who has prepared an account of them in a recent issue of *Mind* (63, No. 249; January 1954). Among the topics considered were some general questions about language, some special questions in the philosophy of logic and mathematics, as well as behaviourism, solipsism, idealism, realism, "the grammar of the word 'God' and ethical and aesthetic statements". The journal also contains a detailed critical notice of Wittgenstein's book "Philosophical Investigations" by P. F. Strawson.

Leicester Museums and Art Gallery: Annual Report for 1952-53

THE forty-seventh annual report of the City of Leicester Museums and Art Gallery for the year April 1, 1952-March 31, 1953 (pp. 44+4 plates; 1953), reflects the steady and continued achievement of this institution. It is an attractive, illustrated production and records faithfully the consolidation that has taken place after the period of considerable reorganization undertaken since the end of the Second World War. The year has been one of close and friendly liaison with local cultural societies, and much extra-mural work has been accomplished in collaboration with the appropriate department in the University College. This means that the Museum buildings are in use on most evenings during the week. The outstanding acquisition of the year was a fine overmantel and oak panelling from Ragdale Hall, Leicestershire, made possible through the generosity of the trustees of the Friends of the Museum Fund.

Non-Destructive Testing Group of the Institute of Physics: Meeting in Birmingham

WITH the appearance of new techniques for proving or sorting materials and components, some of which are complementary to radiography, the Industrial Radiology Group of the Institute of Physics has changed its name to the Non-Destructive Testing Group, and, under its new title and with extended terms of reference, the Group is holding a summer meeting, which will be on a wider field of physical methods of non-destructive testing than on previous occasions. The meeting will be held in the Chancellor's Hall, University of Birmingham, during July 7-10 and will be open both to members and non-members of the Group, subject to the limit of lecture-room capacity of about three hundred persons. Prof. A. J. Murphy, professor of industrial metallurgy in the University of Birmingham, will give an address on the evening of July 7, and on the succeeding three days six papers will be presented dealing with the following topics: isotope techniques; image intensifiers; diffraction mottling; theory and application of electrical and magnetic methods of non-destructive testing; propagation of elastic waves in solids; and selected topics in ultrasonic testing. Abstracts of the contributed papers will be circulated shortly before the meeting, and the proceedings will be reported in the bulletin of the Group and in the *British Journal of Applied Physics*. Enrolment forms (to be returned by May 31) and further information can be obtained from the Deputy Secretary, Institute of Physics, 47 Belgrave Square, London, S.W.1.

Earthquakes during January

EARTHQUAKES caused minor property damage on January 12 near Wheeler Ridge, California (magnitude 6), and on January 25 in the island of São Miguel in the Azores. Earthquakes were also reported as 'felt' on January 2 at Arenas del Rey in Spain; on January 17 in Central Honshu, Japan; on January 18 near the west coast of Greece; and on January 27 and 28 near the coast of Guerrero, Mexico. The greatest earthquakes during the month were on January 12 and 13 (magnitudes 7 and 7½) off the South Island of New Zealand; and other shocks of magnitude 6 and greater occurred, in addition to those mentioned, on January 1 in the Sawee Sea, on January 20 in the Pacific Ocean south of Mexico, and on January 21 in Kenya. Reports have been received from individual stations at Durham, Lwiro (Belgian Congo), Pasadena, Strasbourg, Toledo and Uccle; and from the United States Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association.

The Night Sky in May

New moon occurs on May 2d. 20h. 22m., U.T., and full moon on May 17d. 21h. 47m. The following conjunctions with the moon take place: May 4d. 13h., Venus 3° S.; May 5d. 20h., Jupiter 2° S.; May 16d. 07h., Saturn 8° N.; May 21d. 08h., Mars 1° S. In addition to these conjunctions with the moon, Mercury is in conjunction with Aldebaran on May 19d. 11h., Mercury being 7.2° N.; Venus is in conjunction with Jupiter on May 23d. 12h., Venus 1.5° N.; and Mercury is in conjunction with Jupiter on May 31d. 19h., Mercury 2.2° N. Mercury, in superior conjunction on May 8, is too close to the sun to be seen in the early part of the month; on May 15 and 31 it sets at 20h. 25m., and 22h., respectively, but in the former case this is only 40 minutes after sunset. Its close approach to Jupiter on May 31 has already been pointed out. Venus is an evening star, its times of setting on May 1, 15 and 31 being 21h. 25m., 22h. 05m. and 22h. 30m., respectively. The visible portion of its illuminated disk varies from 0.922 to 0.856, and its stellar magnitude from -3.3 to -3.4. Mars rises at 0h. 10m., 23h. 30m. and 22h. 35m. on May 1, 15 and 31, respectively. It has an eastward motion in the constellation Sagittarius until May 23 when it is stationary, after which its motion is westward. Jupiter sets at 23h. 15m., 22h. 30m. and 21h. 45m. on May 1, 15 and 31, respectively. Its eastward movement from east of ζ Tauri to west of η Geminorum is easily detected. Saturn rises at 18h. 35m., 17h. 35m. and 16h. 25m. at the beginning, middle and end of the month, respectively, and is close to α Virginis; it can be seen until the early morning hours. No occultations take place during May. The η Aquarid meteors are active at the beginning of the month, attaining a maximum about May 6; the radiant is at R.A. 22h. 24m., Dec. -1°, very close to η Aquarii, from which the shower derives its name. For a long time it was believed that it was associated with the debris of Halley's Comet, but there is now some doubt about this.

Announcements

THE Royal Meteorological Society announced the following awards at the annual general meeting held on April 28: Buchan Prize for the period 1949-53

to Dr. R. S. Scorer for his outstanding contributions to dynamical meteorology; Hugh Robert Mill Medal and Prize for 1954 to Mr. C. K. M. Douglas, for his outstanding contributions to our knowledge of the causes of rain. Darton prize awards were also announced as follows: First Prize, for 1953, Messrs. B. J. Mason and R. Ramanadham. Canadian Prizes for 1953: First Prize, Dr. W. L. Godson; Second Prize, Mr. G. W. Robertson.

THE Worshipful Company of Clockmakers (Candlewick House, 116 Cannon Street, London, E.C.4) has decided to institute an award for outstanding achievement in the field of horology. It will take the form of a gold medal, to be known as the Tompion Medal of the Worshipful Company of Clockmakers, and will be awarded, without regard to nationality, not more than once a year.

COLONEL S. J. M. AULD has been elected president of the Institute of Petroleum for the year 1954-55. Colonel Auld was previously president of the Institute in 1937-38.

MR. K. B. ROSS, who until 1951 was general refineries manager for the Anglo-Iranian Oil Co. at Abadan, and has since then been on the Board of Messrs. Costain-John Brown, Ltd., has been appointed director of production in the Industrial Group of the Department of Atomic Energy at Risley. Mr. P. T. Fletcher, chief engineer of the Ministry of Works, has been appointed deputy director (engineering services) in the Industrial Group.

THE following appointments have been made in the University of London: Dr. F. E. Camps, lecturer at the London Hospital Medical College, to the part-time University readership in forensic medicine tenable at that College; Dr. G. E. Francis, senior lecturer at St. Bartholomew's Hospital Medical College, to the University readership in biochemistry tenable at that College.

THE Committee of Privy Council for Agricultural Research and Nature Conservation has appointed Mr. David Lowe, a prominent Scottish horticulturist, and, after consultation with the President of the Royal Society, Mr. J. N. Ritchie, chief veterinary officer of the Ministry of Agriculture and Fisheries, to fill two vacancies on the Agricultural Research Council.

FOLLOWING the resignation of Mr. A. G. Peacock, for seven years secretary of the Scientific Instrument Manufacturers' Association, Mr. E. D. Hart, for many years with Marconi Instruments, Ltd., and lately with the Equipment Division of Mullard, Ltd., has been appointed deputy director of the Association. Miss G. E. Moss, formerly clerk to the Council, has now taken the position of secretary.

THE Section of Mathematical Statistics of the Australian Commonwealth Scientific and Industrial Research Organization has now become the Division of Mathematical Statistics, with headquarters in Adelaide, and its officer-in-charge, Dr. E. A. Cornish, is now chief of the new Division. The main task of the Division is to provide research workers of the Organization with special help in planning their researches and analysing and interpreting their experimental results.

ERRATUM. In the communication entitled "Proposal for a New Ether-Drift Experiment", by Dr. L. Essen (*Nature*, April 17, p. 734), line 23, for "± 1 part in 10¹⁰" read "± 1 part in 10¹¹".

EXTENSION TO THE METALLURGY DIVISION OF THE NATIONAL PHYSICAL LABORATORY

THE extension to the Metallurgy Division of the National Physical Laboratory, which was opened by Sir Lawrence Bragg on April 6, has been made necessary by the continuous development of techniques for the examination of the fine structure of metals and by the growth of interest in the properties of materials at very high temperatures. It consists of a two-story building having a total floor area of about 11,700 sq. ft., of which about 8,800 sq. ft. is experimental working space. Its purpose is to accommodate three Sections of the Division—the Ceramics Section, the X-Ray Section and a new Radioactive Tracer Section. Each portion of the building has been designed to meet the requirements of the particular type of work that will be undertaken in it.

The Ceramics Section is on the ground floor and consists of five laboratories and offices, together with a large furnace room. The Section is mainly concerned with the development and production of refractory ware for use under exacting conditions, especially those involving very high temperatures. Facilities are available for crushing, grinding, forming and drying ware, and the furnace room will permit firing on a considerable scale. Space is also available for physico-chemical research and for the needs of specialized experiments and measurements.

Also on the ground floor is a set of rooms for experimental work on the application of radioactive tracer techniques to metallurgical problems. The purpose is to provide a place where these techniques can be applied under suitable conditions to metallic samples, and to assess their value in metallurgical research. The plan underlying the design and equipment of the Section has been to provide facilities for carrying out on metals of all but the highest activity most of the operations normally applied to metals in a research laboratory. The main feature is the foundry, a lofty, well-lit room equipped with melting furnaces, casting equipment, heat-treatment furnaces, a small bar- and sheet-rolling mill and a suitably protected safe for storing active isotopes. Provision has been made to handle active metal in quantities up to about 6 lb. Next to the foundry is a combined workshop and laboratory for metallographic preparations, and next again is a combined chemical and physical laboratory in which chemical analyses and measurements of activity will be carried out. The Section is approached through a semi-sealed door and changing rooms, and is provided with its own air-conditioning system arranged so as to produce a slightly negative pressure. This avoids the possibility of contamination passing to the rest of the building, which is kept at a slightly positive pressure by its own system of air circulation. At selected points in each room, openings to the extract duct are provided, to which extensions to hoods over machines and other equipment may be attached. The rooms are designed to be easily washed down, and have floor ducts and sinks down which all active liquid passes to delay tanks situated under a separate pump house. Separate sinks and drains are provided for non-active liquids (for example, cooling water from pumps, etc.). Warning bells and klaxon alarms are incorporated

in the air-conditioning and delay-tank systems to indicate any abnormal feature of their operation.

The upper floor is designed for X-ray diffraction studies of metals and for electron microscopy. The main feature is a single, very large room divided by means of easily removable partitions into a number of cubicles and small laboratories, each of which is intended to contain a single piece of equipment and can be independently darkened. In this way the need of the individual worker to have sole control of his own equipment is combined with adaptability. As a corollary to the use of removable partitions, all services in the Section are carried in a carefully planned system of wall and floor ducts. In addition to the standard services provided throughout the building, there are, in this Section, a circulating system of clean distilled water at 50 lb./sq. in. pressure and 20–25° C. temperature for cooling purposes, and a quiet phase of 230-volt a.c. for apparatus requiring short-term mains stability. Among the pieces of equipment at present installed may be mentioned units primarily intended for standard X-ray techniques, two sets for Geiger-Müller counter work for high-precision measurements of diffraction-line intensities and preferred orientation, one set for work requiring a fine-focus source of radiation, electron microscope and a soft X-ray spectrograph with a recording microphotometer.

In his opening address, Sir Lawrence Bragg referred to the history of the Division, going back to 1901 and to the succession of eminent men who had filled the post of superintendent—Sir Harold Carpenter, Dr. W. Rosenhain, Dr. C. H. Desch, Dr. C. Sykes and, at present, Dr. N. P. Allen. He then went on to say: "I am particularly pleased to be opening the new extension, because all three of its main interests are related to interests of my own. One Section will be devoted to X-ray work, particularly on metals, and I should like to remind you how greatly our country has contributed to this field; in fact, it has been at times almost a British monopoly. Brilliant work on alloys was started by Westgren and Phragmen in Sweden in the early days, but it fell to Owen and Preston here, and to Bradley, who was then with me in Manchester and afterwards came here, to develop the patient study of the structure of alloys which has helped us so much to understand them. Sykes also made contributions to the theory of alloy structure. His experiments and the theories developed by Williams enabled us at Manchester to start the investigations into the order-disorder phenomena, which have exerted a great influence in the study of many other problems of the solid state. The X-ray study of alloys is a rich field to explore, and it is proper that there should be a strong centre of this work at the National Physical Laboratory.

"Another fascinating line which you are to develop here is the application of tracer techniques to problems of metal physics. Metal physics is an extraordinary subject; there is such a vast accumulation of empirical knowledge about the behaviour of metals and so little satisfactory theory behind it. It is an extraordinary position for a subject which has such

immense technological importance. This seems to me to be an ideal activity for the National Physical Laboratory. You will have a special laboratory designed for the purpose and will find by experience how this new technique can be applied. You will be marking a trail which it will be easier for others to follow".

Sir Lawrence then said it must appear he was claiming a finger in every pie; but ceramics are really artificial minerals, and mineral structures have long fascinated X-ray analysts. Minerals are structures of great stability and resistance to change, and these are just the qualities needed for refractories. The juxtaposition of the ceramics and X-ray sections seemed to him completely appropriate, and collaboration between them should be very fruitful. He concluded: "The National Physical Laboratory was founded to keep the country's standards, but it has come to have another function, that of setting standards in experimental investigation. It ought to preserve a judicial and impersonal attitude, contain equipment which is a model of its kind, and be a centre to which one can go for advice, advice which depends upon an impartial review of what is going on all over the country and a readiness to adopt the best ideas whatever their source. With its unique position it has a great part to play in the interchange of ideas and the improvement of standards".

The opening of the main door of the building was performed by Sir Lawrence using a presentation key, made in the Division, of titanium and ornamented with eight other metals, each of which represented some major research or development activity of the Division during the fifty-three years of its existence.

H. A. SLOMAN

UNIMOLECULAR GAS REACTIONS

A MEETING to discuss the theory of gas-phase unimolecular reactions and its applications to specific reactions was held in the Department of Chemistry, University College, London, on December 4. Dr. N. B. Slater (Leeds) opened the discussion by describing his approach to the problem. If it is assumed that a molecule has a few unstable states (r) of high energy which have lifetimes L_r^{-1} , then if p_r is the probability of the r th state, ω the effective collision frequency per molecule and k the rate-constant,

$$k = \sum_r \frac{p_r \omega L_r}{L_r + \omega} \quad (1)$$

At high pressures ($\omega \gg L_r$) the majority of energized molecules will be deactivated, and (1) reduces to (2):

$$k = \sum_r p_r L_r \quad (2)$$

The reaction-rate is thus the rate at which a molecule possessing at least an energy E_0 attains a critical configuration. The critical configuration may be taken as a large extension of one of the internal co-ordinates of the molecule. Treating the latter as a classical vibrating system, it can be shown¹ that the rate of reaction is given by

$$k = \nu \exp(-E_0/RT), \quad (3)$$

where

$$\nu = \frac{\sum_i \alpha_i^2 \nu_i^2}{\sum_i \alpha_i^2}, \quad E_0 = \frac{q_i^2}{\sum_i \alpha_i^2} \quad (4)$$

The ν_i are the vibration frequencies of the molecule and α_i the amplitude factors, both of which are constants of the molecule in question; q_i is the critical extension of the co-ordinate corresponding to decomposition, and E_0 the activation energy. No attempt is made in the theory to calculate E_0 .

At low pressures the rate of dissociation becomes of the same order of magnitude as the rate of deactivation, and so (1) no longer reduces to (2). However, on the basis of the present theory, it is possible to develop from (1) an expression for k/k_∞ , the ratio of the rate at any pressure to the limiting rate at high pressure². Calculations have shown that small molecules should show first-order kinetics only at impossibly high pressures, six or more atoms being necessary to give first-order rates below a pressure of one atmosphere. Dr. Slater showed that the rate as given by (3) and (4) is essentially reproduced at high temperatures by a quantum treatment and that these expressions are little altered by taking account of anharmonicity of the vibrations. The relation of the theory under discussion to that of Kassel and to the transition state theory was described.

Dr. A. F. Trotman-Dickenson (Manchester) gave a critical survey of the experimental field. He stated that, in his opinion, only eight decompositions have been reasonably fully investigated over a large range of pressure, which undoubtedly exhibit quasi-unimolecular behaviour: they are nitrous oxide, dinitrogen tetroxide, nitrogen pentoxide, fluorine oxide, CH_3NNCH_3 , C_2H_6 , *cyclo*- C_3H_6 , and *cyclo*- C_4H_8 . The last two decompositions³ provide the most straightforward examples of the dependence of a unimolecular rate-constant on pressure. The observations could not be explained on the original Hinshelwood-Lindemann theory. But either the Kassel theory or the Slater theory will fit the results for cyclopropane very well, though the latter theory is much to be preferred because no arbitrary parameters are introduced. A table of the relative efficiencies of various inert gases in maintaining the rates of five reactions was shown by Dr. Trotman-Dickenson, from which it can be inferred that 'kinetic theory' collisions between two complex molecules result in an equilibrium distribution of internal energy between the molecules, whereas equilibrium is attained in only one collision in ten of nitrogen with a complex molecule.

The pyrolyses of alkyl chlorides were discussed by Dr. K. E. Howlett (Bedford College, London). Although two mechanisms—unimolecular and radical chain—have been observed, about ten compounds studied have proved to be pure unimolecular. In each case, critical pressure regions exist, and the number of degrees of freedom required to account for these are reasonable⁴. Inert gases, while having no effect upon the high-pressure rates, are capable in various degrees of restoring the low-pressure rate to the high-pressure value. Ethylene has been found to be the most efficient in transferring energy, and helium the least⁵. Further, the efficiencies appear to be of the same order as predicted by the kinetic theory, in marked distinction to the calculations of O. Zener. It is also observed that the range of efficiencies is never very great. Finally, Dr. Howlett reported that Miss A. M. Goodall has found the inhibited decomposition of trichlorethylene to be a homogeneous second-order, non-chain process, in accord with Slater's predictions for small molecules.

Dr. F. J. Stubbs (Oxford) dealt with the pyrolysis of hydrocarbons. A limiting reaction-rate in the presence of inhibitors is observed, which is independent of the nature of the inhibitor and identified with a molecular process. The rates are found to be pressure-dependent. Two modes of decomposition are found, as typified by ethane and *n*-pentane. In the former case the activation energy is independent of pressure, and there is a single transition from second to first order as the pressure rises. In the latter case the activation energy falls as the pressure rises, and the reaction order changes from two at low pressures to one, then towards two and finally reaches one again at high pressures. For compounds like *n*-pentane, the rate can be divided into two terms each corresponding to a unimolecular reaction, one of which (predominant at low pressures) is characterized by a high H and A , and the other (predominant at high pressures) is characterized by a low H and normal A . In the latter case, it is suggested that the activation process is essentially confined to a C—C bond, whereas, in the former, C—H activation is involved as well. This is assumed to give rise to a multiplicity of reaction paths, corresponding to the carbon nucleus being surrounded by a mobile sheath of hydrogen atoms. The magnitude of A and H can be interpreted on this basis.

The pyrolysis of mercury alkyls in the presence of nitric oxide as a chain inhibitor was described by Dr. B. Gowenlock (Swansea). Under these conditions both a nitroso compound and an oxime were obtained in the products. In the case of dimethyl mercury* the activation energy was about 6 kcal. mole⁻¹ less than the energy required to break both bonds, and this is considered to be the energy required to break the first Hg—C bond; the frequency factor was about 10¹³ sec.⁻¹. However, with di-*n*-propyl mercury* and di-isopropyl mercury¹², H corresponded to the energy required to break the two bonds and A was of the order of 10¹³ sec.⁻¹. The increase in the frequency factor corresponds with the spreading of the activation energy over two bonds.

Further evidence in this connexion was provided by Dr. E. Warhurst (Manchester). While diphenyl mercury behaves like the dipropyl mercury compounds, phenyl mercuric chloride and bromide show the same type of behaviour as dimethyl mercury. This series of compounds shows an interesting type of behaviour as the number of oscillators in the reacting molecule increases. Further evidence for frequency factors of 10¹⁴–10¹⁵ sec.⁻¹ coupled with 'high' activation energies is provided by a series of carbonyl-containing compounds studied by M. Szwarc and his co-workers.

Dr. H. O. Pritchard (Manchester) pointed out that an explanation of the observed differences in behaviour of dimethyl mercury and di-isopropyl mercury upon pyrolysis would probably have to await a further interpretation of the vibrational spectra of mercury di-alkyls. Again, uncertainties in the strengths of C—H bonds make it possible that the activation energy for the di-isopropyl mercury decomposition may be significantly greater than the sum of the energies required to break the two Hg—C bonds. Such behaviour is actually observed in azomethane, where the activation energy is approximately double the sum of the dissociation energies for the two N—CH₃ bonds. However, in this case it is reasonable to assume that the activation energy

is all concentrated in one N—CH₃ bond, since the frequency factor is only 10¹⁴ sec.⁻¹.

The case of dimethyl mercury was referred to again by Dr. L. H. Long (Exeter), who reported an activation energy for the unimolecular decomposition in excellent agreement with that of Gowenlock, although obtained by a different technique. As was also noted by the previous two speakers, the frequency factor tends to rise with increasing pressure.

Dr. J. O. Hirschfelder (Wisconsin) emphasized the importance of a theoretical calculation of energy transfer at surfaces. There is strong experimental and theoretical evidence to indicate that molecules obtain their energy of activation by collision with the walls rather than with other molecules in the gas phase. This would require a considerable modification of the Slater theory and lead to somewhat different results. In connexion with the Eyring theory of bimolecular reaction-rates, Dr. Hirschfelder underlined the necessity of allowing for rotation in the activated complex. With the H₂I₂ complex, for example, unless this factor is allowed for, the rate comes out too small by a factor of about 1/300. A value in better agreement with experiment is obtained if rotation is considered. It is to be hoped that the future development of reaction-rate theory will include both unimolecular and bimolecular reactions in a uniform treatment.

Some results of experiments on the pyrolysis of alkyl bromides carried out by Drs. J. H. S. Green and P. J. Thomas and Mr. G. D. Harden were described by Dr. A. Maccoll (University College, London)¹¹. Whereas secondary and tertiary bromides decompose cleanly by a unimolecular mechanism, the primary compounds decompose by a mixed chain-unimolecular mechanism, the chain part of which, however, may be eliminated by the use of cyclohexene as an inhibitor. In all cases of unimolecular decomposition, the frequency factors are of the order of 10¹³ sec.⁻¹. An interesting series is that of the normal bromides, for which (apart from ethyl) the activation energy is constant and the rates appear to approach a limiting value as the chain-length increases.

Prof. H. C. Longuet-Higgins (King's College, London) outlined a quantal attack on the problem of reaction-rates, which he has been developing in collaboration with Mr. P. W. Higgs. In the case of a molecule capable of dissociation and which cannot be considered as being in a pure quantum state, the outward flux across a given value of a co-ordinate may be calculated. For an assembly of simple harmonic oscillators in thermal equilibrium, such a calculation leads to the quantal expression for the reaction-rate. It is found that at high temperatures (the classical limit) equation (3) is recovered, but at intermediate temperatures the rate expression departs from (3); in particular, a finite rate is predicted at 0° K. It was suggested that perhaps the theoretical criterion of reaction $q > q_c$ would need to be re-examined in the light of the experimental criterion, which is the appearance of new chemical species. The full solution of the problem in the case of many degrees of freedom is not yet available.

The flexibility of the Eyring treatment in its ability to account for a wide variation in v was referred to by Dr. B. Atkinson (Imperial College of Science and Technology, London). High value of v can be interpreted in terms of a 'loosening' of the molecule in the transition state and low values in terms of a 'stiffening'.

A number of points emerged as to the present state of knowledge of unimolecular reactions. In the first place, there now seems to be a large number of well-established gas-phase unimolecular reactions. Secondly, experimental investigations of the low-pressure region have enabled relative collision efficiencies for energy transfer to be estimated. Thirdly, there appears to be quite a wide range of frequency factors. Fourthly, it is desirable to extend the theoretical treatment along quantum lines. Finally, recognition of the possible multiplicity of reaction paths may be a fruitful line of approach.

The meeting closed with an expression of gratitude to Prof. C. K. Ingold, of University College, London, through whose interest the conference was made possible.

SCIENTIFIC AND TECHNICAL DOCUMENTATION IN TURKEY

TECHNICAL Assistance projects in Turkey, some of them operating, others to come into operation if and when funds are available, cover a great variety of subjects: public administration, economic research, civil aviation, statistics, maternal and child health, diseases control, water resources development, oil resources development, fisheries development, hydrogeology, seismology, and various others. Bibliographical and documentation services, needed by many of them, are also included.

The National Bibliographical Centre is one of three Unesco projects under the Expanded Programme of Technical Assistance in Turkey. It was set up in 1952, with the assistance of two library experts: a specialist in bibliography, from France, and a specialist in documentation, from the United Kingdom. The Centre is housed at the National Library in Ankara and, apart from co-operating with Technical Assistance projects, maintains close contact with government departments, university faculties, scientific societies, educational institutes, research stations, industrial undertakings and, of course, other libraries.

The main objective of the Bibliographical Centre is to assure the availability of information to all Turkish programmes for scientific, technical and economic development. This emphasis on Turkish affairs does not, however, preclude it from collaborating in a system of international exchanges of scientific information and so render valuable service to the region, and to the world.

With financial aid earmarked for the purpose by Unesco Technical Assistance, the Centre brought together a much-needed collection of handbooks, monographs, bibliographies, catalogues and other

library tools in many different languages. This useful reference library, open to *bona fide* research workers, has meanwhile become indispensable to staff and readers alike.

Under its regular programme, Unesco has established in Istanbul a branch office of its Middle East Science Co-operation Office, the headquarters of which are located in Cairo. The Istanbul Office acts as an outpost of Unesco in Turkey, and among its activities has been the *ad hoc* supply of scientific information requested by Turkish scientific workers. The United States Information Service offers similar facilities within the range of United States sources. The Middle East Science Co-operation Office in Cairo issues an abstracting journal in the English language which covers the Middle East countries and includes several periodicals published in Turkey.

Fuller coverage of Turkish periodicals in the pure and applied sciences, technology and so on, is now provided by "Türkiye Makaleler Bibliyografyası" ("Bibliographie des articles parus dans les périodiques turcs"), issued by the National Bibliographical Centre. It is published at irregular intervals, is arranged by Universal Decimal Classification numbers, with the titles of articles in Turkish and French, and has an author index. Translations or abstracts of specified papers, and microfilms of the original texts, are supplied on request.

As a means of meeting and co-ordinating incoming demands for foreign articles which may be available in Turkey, the Bibliographical Centre has compiled, and keeps currently up to date, a union catalogue of foreign periodicals in Turkish libraries. It is now in its second edition.

Scientific papers published in other journals are obtained as microfilms from abroad, against payment in Unesco coupons or, mostly, on an exchange basis. The first exchange arrangement was concluded in March 1953, between the National Bibliographical Centre in Ankara and the Centre National de la Recherche Scientifique in Paris. This placed at the disposal of Turkish men of science a substantial part of the world's scientific literature, and makes Turkish contributions available to scientists in the West. The microfilm laboratory at the Turkish National Library, previously almost exclusively engaged on the copying of manuscripts, has adjusted itself admirably to the new tasks, and a microfilm camera and microfilm reading machines have been imported from Britain.

Approach to documentation may be two-fold—short-term and long-term—one taking care of immediate needs and the other making provision for potential requirements. It has been the policy of the Centre to prepare for both, trying to do justice at the same time to border-line cases, of which there are many.

Inquiries for documentation were received from quarters interested in subjects as widely apart as: palaeontological research; fish culture and fish industry; methods of preserving and utilizing agricultural products; and industrial accidents and workmen's compensation—to mention only a few. It had, moreover, been agreed between Unesco and the World Health Organization, also represented in Turkey, that every possible help should be given to medical libraries and medical documentation in Turkey. The Bibliographical Centre was also called upon to act as liaison for a direct approach between research and study projects in Turkey and their opposite numbers elsewhere. An agricultural research

station was referred to the Food and Agriculture Organization; an industrial information unit put in touch with the Department of Scientific and Industrial Research; a chemistry department with the Gmelin Institut für Anorganische Chemie; and a government agency with the International Organization for Standardization. Such liaison has been essential, for, through it, has been created a broader footing for scientific and technical documentation; in the terms of Technical Assistance, "the activity started on the right lines".

LUCIA MOHOLY

LATERITES AND BAUXITES OF ANTRIM

THE first memoir to be published by the Geological Survey of Northern Ireland*, prepared by Mr. V. A. Eyles and other workers, will be widely recognized as a contribution to the geochemistry and mineralogy of laterite and bauxite of outstanding importance and permanent value. Equally welcome will be the promised companion volume on the detailed geology of these rocks as they occur in the Interbasaltic Horizon of Co. Antrim. The present work deals with the nature of the chemical changes concerned in the process of lateritization and of the composition of the Interbasaltic lateritic rocks themselves. The latter were formed during a prolonged pause in the Tertiary volcanic activity responsible for the Antrim basalts. At an early stage in this Interbasaltic period there was a brief recrudescence of activity characterized by the eruption of highly silicic lavas. Intense erosion followed, with removal of most of the rhyolites and complementary deposition of thin sediments largely composed of rhyolitic debris. Towards the end of the lateritization period a thin coal seam was formed from the vegetation that flourished over the area. An interesting note records that Dr. J. B. Simpson finds the floral remains from a coal associated with bauxite near Portrush to be of essentially the same age as the corresponding horizon in Mull, to which he is inclined to ascribe a late Miocene or early Pliocene age. This is so much later than has hitherto been thought probable that the publication of Dr. Simpson's palaeobotanical researches will be eagerly awaited. The Interbasaltic period was terminated by the outpouring of the Giant's Causeway and later basaltic flows. At the same time, or later, basaltic dykes were intruded, and these, cutting through the lateritic rocks, affected marked metamorphic changes.

The Irish laterites and bauxites were formed in two distinct stages: (a) alteration to lithomarge, consisting of kaolinite or halloysite; and (b) lateritization, involving further desilication with formation of gibbsite ($\text{Al}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$) together with oxides of iron and titanium. With long-continued operation of the process the iron oxides tend to concentrate towards the surface, forming an increasingly ferruginous laterite and eventually a workable iron ore, overlying a layer of richly aluminous laterite or bauxite. In Ireland, unfortunately, neither complete desilication of lithomarge nor clean separation of aluminous from ferruginous laterite has occurred over more than

limited areas. The prevailing types are lateritic lithomarges and ferruginous or siliceous laterites. It appears that quartz, originally present in a parental rock, may persist unchanged; the possibility of, and the conditions governing, the total elimination of quartz still require further investigation. A chemical method, devised and described by Mr. O. O. Harvey, is given for the quantitative determination of quartz in the presence of combined silica.

Much valuable information has been obtained from the application of the X-ray diffraction technique to selected specimens. The chief minerals recognized include meta-halloysite and kaolinite; gibbsite and boehmite (but not diasporite); hematite, goethite and magnetite; and anatase. Chamosite has been found in certain parts of the laterite horizon which exhibit a greenish tinge. Since the formation of chamosite requires reducing conditions, its occurrence implies that it is a secondary mineral relative to the lateritic minerals with which it is now associated. The abundance and distribution of various minor elements has been determined by Dr. S. Landergrén, whose results demonstrate enrichment of the laterites in vanadium and probably in chromium.

Discussing the geological conditions influencing the formation of the several hydrated oxides of aluminium, Mr. Eyles points out that the widespread distribution and prevalence of the gibbsite type of bauxite suggests that this is the variety normally developed. He presents detailed evidence to justify the tentative conclusions: "(i) that the formation of monohydrates in large amounts results from a change of geological environment superimposed on gibberitic laterites after the formation of the latter; (ii) that increased pressure resulting from subsidence, or dynamic action, or both, and not rise in temperature alone, may often be the main, though possibly not the sole, factor causing the large-scale development of monohydrates of alumina; (iii) that while igneous intrusions or lava flows alone may cause localized development of boehmite in laterite deposits, pressure is probably essential for the formation of diasporite in large quantities".

Mr. Eyles and his colleagues have made this a model investigation of its kind. It is to be hoped that their lead will be followed, so that it may no longer be necessary to direct attention to the fact that "descriptions of foreign laterite are not always sufficiently complete to permit generalizations to be drawn from the facts presented".

A. HOLMES

CARNEGIE TRUST FOR THE UNIVERSITIES OF SCOTLAND

ANNUAL REPORT FOR 1952-53

THE fifty-second annual report of the Carnegie Trust for the Universities of Scotland, covering the academic year 1952-53*, deals with a period before the most recent regulations of the Scottish Education Department for the award of bursaries by Scottish education authorities became effective so far as the Trust is concerned; but the executive committee to the trustees points out that the amounts awarded in terms of these regulations constitute a

* The Composition and Origin of the Antrim Laterites and Bauxites. By V. A. Eyles, with mineral determinations by X-ray methods by F. A. Bannister (British Museum, Natural History) and G. W. Bendley and J. Goodyear (University of Leeds). (Memoir of the Geological Survey of Northern Ireland.) Pp. vi+90. (Belfast: H.M. Stationery Office, 1953.) 12s. 6d.

* The Carnegie Trust for the Universities of Scotland. Fifty-second Annual Report (for the Year 1952-53). Submitted by the Executive Committee to the Trustees on 22nd February, 1954. Pp. iv+72. (Edinburgh: T. and A. Constable, Ltd., 1954.)

difficult problem for the Trust. Applications are now being received from students whose parents or guardians in the earlier years of its history would not have had recourse to the Trust, and each application presents a case in itself. Moreover, since individual education authorities frequently withdraw the bursary for a further year if the student fails to pass all his degree examinations at the appropriate time, the student often applies to the Trust for assistance towards his class fees, and the whole circumstances attendant on failure must be reviewed. While, for the time being, the executive committee has awarded class fees when there seemed to be a reasonable prospect of the student's being able to reinstate himself, it shares with the education authorities considerable anxiety as to the total effect of these bursary regulations emanating from the Education (Scotland) Act, 1946. The 1,301 students assisted during 1952-53 received £20,003 compared with £15,089 to 1,028 students during 1951-52; repayments by former beneficiaries were £2,062 from 34 beneficiaries, compared with £1,985 during 1951-52.

The amount devoted to the research scheme during 1952-53 was £32,646, or some £5,000 less than during 1951-52, and scholarship awards were made more rigorously. The special fund for assisting the publication of work embodying original research now stands at £9,059. Both the scheme recently introduced to give opportunity for senior members of university staffs to go abroad for periods of research up to one year, and the block grants to the four universities to enable members of their staff to use their vacations fruitfully in research, whether at home or on the Continent of Europe, are regarded as successful. Grants were also made to Scottish learned societies, to "A Dictionary of the Older Scottish Tongue", "The Scottish National Dictionary", "The Scottish Historical Review", and, through the universities, to "The Third Statistical Account". Appended to the report are lists of publications by fellows, scholars and recipients of grants received since September 1952, of recipients of grants and of assisted papers, and a résumé of reports upon the work of investigators under the research scheme.

In the mathematical, physical and engineering section, Sir Richard Southwell comments particularly on Dr. W. Paul's work on the effect of high pressures on the properties of semiconductors, Dr. A. G. Mackie's work on the hodograph method for the problem of compressible-flow around sharp corners, and Mr. P. B. MacFarlane's study of Pleistocene changes of sea-level. In medicine, I. A. Macpherson has made marked progress in studying haemagglutination by viruses and its inhibition by bacterial polysaccharides, and J. Grieve on the treatment of experimental peritonitis in rats with phthalylsulphathiazole.

In chemistry, Dr. T. R. R. McDonald's work on the crystal structure of ammonium bifluoride promises to yield valuable information about the nature of the hydrogen bond. Dr. A. R. M. Gibb has made excellent progress in synthesizing tropolone derivatives in his work on the preparation of compounds, structurally related to colchicine, which might possess its antimitotic effects but not its poisonous properties; Miss Evelyn E. B. Smith has discovered several new reactions involving uridine pyrophosphate derivatives, and her investigation of the enzymic mechanisms concerned has now gained her a Beit fellowship for medical research to study enzymic mechanisms at the University of Glasgow. Other investigations in chemistry noted in the

advisers' report are those of W. J. Bremner on the flow of gases through a porous plug; A. J. Sorrie on the synthesis of benzotropolone, in which he has discovered the effectiveness as a condensing agent of a fused mixture of sodium chloride and aluminium chloride; R. Logan on the use of radioactive phosphorus to find the rates at which phosphorus is taken up into the different nucleotides in the constituents of the cytoplasm of the liver cells in the domestic fowl; and G. A. J. Goodlad on the enzymes found in the liver which effect transformations of sugar phosphates.

In biology, Dr. J. W. H. Lawson has commenced a lengthy investigation on the systematics and biology of aquatic species of the Chironomids, G. D. Scott is investigating the ecology and physiology of lichens, Miss Janet E. O. Towers has studied the chromosomes in amphibian oocytes, D. C. W. Smith has done much work on the endocrine control of osmoregulation in Salmonids and E. A. Salzen has made a good beginning in a study of the rate of growth of insect embryos at different stages of development.

AVERAGES OF BRIGHT SUNSHINE AND TEMPERATURE FOR GREAT BRITAIN AND NORTHERN IRELAND

THE Meteorological Office has recently published two pamphlets giving, respectively, averages of sunshine and of temperature for Great Britain and Northern Ireland during the period 1921-50*. The sunshine measurements are all made by the Campbell-Stokes instrument, which does not record sunshine below a certain level of intensity, so that the averages refer to 'bright' sunshine. The pamphlet gives average annual and monthly totals and daily means for the months and the year for 187 stations distributed all over Great Britain and Northern Ireland. The records show that, on the average, the Isle of Wight and the Sussex coast are the sunniest areas, with an annual average of more than five hours a day. This area is sunniest in summer as well as in winter. The least sunny rural areas are north and mountainous districts of Scotland, in which some stations average a little less than three hours a day. Sandown had most sunshine in the period with an annual average of 1,840 hr., but was very closely followed by Worthing, Ventnor and Eastbourne. The publication contains useful material for the study of the loss of sunshine in the centre of great cities. It is noteworthy that Bunhill Row in the City of London averaged 3.45 hr. a day against the 4 hr. of Kew and Hampstead, and Manchester (Whitworth Park) 2.9 hr. against 4.1 hr. at Hoylake and Southport. The loss of sunshine in cities is greatest, both absolutely and relatively, in winter. The publication includes a table comparing the averages for 1901-30, 1906-35 and 1921-50 at seven well-distributed stations. The mean daily sunshine at Birmingham, 3.56 hr., was the same in 1921-50 as 1901-30, but the other stations show reductions of up to 0.09 hr.

* Air Ministry: Meteorological Office. *Averages of Temperature for Great Britain and Northern Ireland, 1921-50* (M.O. 571); pp. 11+36; 2s. *Averages of Bright Sunshine for Great Britain and Northern Ireland, 1921-50* (M.O. 572); pp. 11+33; 2s. (London: H.M.S.O., 1953.)

The pamphlet on temperature contains monthly and annual averages of maximum, minimum and mean, half (maximum plus minimum), temperatures in degrees Fahrenheit. The lowest annual average temperature recorded, 43.5° at Braemar (1,111 ft.), is 9 deg. below the highest, 52.5° at Scilly. The mean July maximum ranges from 73.4° in London to 57.8° at Lerwick. In January Cornwall has the highest maxima, with means of 48–50°, but over most of England and Scotland mean maxima are between 42 and 45°. It is necessary to go to stations at heights of more than 500 ft. to find mean January maxima below 40° (Braemar 39.4°) or mean January minima below freezing point (Balmoral 28.4°). Comparisons between the monthly and annual averages for the periods 1901–30, 1906–35 and 1921–50 are given for seven stations. At all the stations there was an increase in mean annual temperature of about 0.5 deg. from the first to the third period. The increase, at about 1 deg., was most marked in summer. Spring and autumn also were slightly warmer; but winter was slightly colder. It is particularly interesting that the difference between the mean annual temperature of the two periods should be so uniform over the whole country.

CORPUSCULAR ECLIPSE IN THE F_2 -LAYER AND ITS ASSOCIATION WITH SOLAR FLARES AND M-REGIONS

By Dr. PRABHAT K. SEN GUPTA

Meteorological Office, Safdarjung Airport, New Delhi
and

S. N. MITRA

Research Department, All India Radio, New Delhi

THE fact that certain intense magnetic storms tend to occur about a day after the visual observation of eruptions (flares) on the sun has led to the belief that these storms are caused by the arrival of fast beams of corpuscles (which taken as a whole are neutral) from the sun having velocities of the order of 1,000–2,000 km./sec. The most direct evidence of the presence of fast incoming particles has been provided by the observations of Mainel¹ during an intense auroral display on August 18–20, 1950. By pointing his spectrograph towards the magnetic zenith and comparing the result with that obtained with the spectrograph towards the magnetic horizon, he found that the $H\alpha$ line had a violet shift (λ 71 Å. for the wing and λ 10 Å. for the maximum) which corresponded to a velocity of 3,200 km./sec. for the incoming protons.

In the ionospheric regions the effect of the solar flares is manifested in the form of Dellinger type of fade-outs, which synchronize with the time of the flares, indicating that it is the ultra-violet light emitted from the solar flare which is responsible for the effect. S. N. Mitra and Mazumdar² found from an analysis of Delhi records for the years 1946–49 that a number of the flares were followed 20–40 hr. later by further fade-outs. For example, out of thirteen flares of type 3 and 3+, four were accompanied by simultaneous fade-outs, and in three cases, fade-outs occurred 20–40 hr. later. The other six

flares were not, however, attended by simultaneous or later fade-outs. During the same period, twenty-three flares of type 2 had been reported, and they found one of these flares to be associated with simultaneous fade-out; in two cases the fade-outs were delayed by 20–40 hr. and the rest of the flares were apparently ineffective in causing fade-out.

The delayed fade-outs which are found to set in about one or two days after the visual observation of a solar flare may be attributed to the action of fast neutral beams of corpuscles originating from the flares, and speeding towards the earth with velocities of the order of 1,600–800 km./sec. Chapman³ pointed out that if a portion of the ionization in the ionospheric layers is caused by the impact of a solar corpuscular stream, an effect should be observable during solar eclipses. He showed that a corpuscular eclipse should occur about two hours earlier than the optical eclipse if the velocity of the corpuscles is taken to be 1,600 km./sec. Later, Chapman⁴ gave reasons why the ideal conditions for the corpuscular effect to be recorded are not likely to be present every time. We wish to point out that there are a number of eclipse observations on record where the investigators have directed attention to the presence of a corpuscular eclipse in accordance with Chapman's ideas: for example, those of October 1, 1940, at Queenstown by Pierce⁵; January 25, 1944, at Huancayo by Ledig *et al.*⁶; February 25, 1952, at Delhi by S. N. Mitra⁷, and on the same occasion at Banaras by S. S. Banerjee *et al.*⁸. In Fig. 1, a few examples have been reproduced with the values of f_oF_2 prepared from the observations, plotted against L.M.T. A corpuscular effect is clearly seen in Figs. 1 (b) and 1 (c) about 2–2½ hr. before the optical eclipse.

Source of Corpuscular Streams

The presence of the corpuscular eclipse about two hours before the optical eclipse provides evidence that fast corpuscles are coming with velocities of the order of 1,600 km./sec.; but it does not indicate whether these corpuscles are associated with solar flares or other disturbed regions of the sun. Judging from the high percentage of magnetic storms and simultaneous radio fade-outs which do not seem to be associated with any observed flare at all, it appears that there may be some other agency on the sun which emits the corpuscles in question, for S. N. Mitra and Mazumdar² found that out of 122 fade-outs recorded during the years 1946–49 at Delhi, 81.2 per cent apparently had no connexion with any flare at all. This encourages us to link up the corpuscular radio fade-outs with *M*-region activity.

It is well known that some of the moderate magnetic storms which seem to have no connexion with visible solar flares have a tendency to recur every 27 days with the synodic rotation of the sun. These magnetic storms, also known as *M*-storms, have been attributed by Bartels⁹ to unidentified active regions of the sun which he calls *M*-regions. The physical nature of the *M*-regions has not yet been established with certainty, nor have the *M*-regions been yet clearly associated with any prominent physical feature on the sun. Waldmeier¹⁰ originated the idea that the intensity of the *O*-regions, that is, the coronal regions of bright line emission (particularly λ 5303), could be used as an index of the activity of *M*-regions. The analysis of Shapley and Roberts¹¹ for the years 1942–44 during a period of sunspot minimum indicated that the appearance of

Fig. 1. Variation of the F_2 -layer ion density during solar eclipses

a bright coronal patch (C -region) at the east limb of the sun was followed three to four days later by the onset of M -storms. Trotter and Roberts¹³ and Müller¹² confirmed the ideas of Shapley and Roberts from the records of 1952 (which is close to the next period of sunspot minimum) and also estimated the lag to be about three days. Allen¹⁴ has associated the onset of M -storms with the central meridian passage of coronal streamers, and is of the opinion that the corpuscles responsible for the M -storms take about one day for intense storms and longer for moderate storms to reach the earth. Von Klüber¹⁵ supported Allen's views from his observation of the solar corona during the total solar eclipse on February 25, 1952, at Khartoum, when a long and intense streamer was seen at the east limb of the sun. Waldmeier¹⁶ suggested from a scrutiny of the 1939-40 observations that the M -storms occurred about one day after the central meridian passage of the bright coronal patches. Later he¹⁶ expressed the view that the bright coronal regions were only partly responsible for M -region activity, which he believed on further consideration to originate in the neighbourhood of large sunspot groups after the disappearance of the spots. He also directed attention to the fact that as long as new spot groups did not appear, the areas vacated by spots were associated with stationary prominences and coronal streamers. Maxwell¹⁷ cited an example when M -region activity developed 27 days after an intense radio emission, which was associated with a decaying sunspot group.

The lesson of these observations appears to be that the mystery of the M -regions on the sun is still

unsolved. But they bring out clearly the inference that the M -storms develop as a result of a corpuscular effect, the corpuscles taking, according to different views, about one to three days to reach the earth. (Wulf and Nicholson¹⁸ have, however, suggested that the M -storms are caused by intense ultra-violet light from areas of bright calcium and hydrogen flocculi when appearing at the east limb of the sun.) The corresponding velocities would be of the order of 1,600-600 km./sec. The strength of the storm would obviously be governed by the speed and intensity of the corpuscular stream.

The moderate M -storms have been known to persist for months through several rotations of the sun, indicating apparently that the slower corpuscles with velocities of 800-600 km./sec. are predominantly emitted by the M -regions. These slower particle streams, if they exist, should give rise to a similar corpuscular eclipse in the variation of f_2P_2 , about four to six hours earlier than the corresponding optical eclipse, provided such particles are able to penetrate the F_2 -layer. Fortunately, the analysis of a number of ionospheric data secured by different observers at widely different stations, and quite independent of each other, confirms this view. A glance at Figs. 1 (a) and 1 (c) quoted above shows that at about 5 hr. before the time of maximum of optical eclipse there was a significant drop in the curves, which could be interpreted as a corpuscular eclipse due to corpuscles having velocity of the order of 640 km./sec. Smith-Rose¹⁹ has also reported that the observations carried out near Moscow during the eclipse of July 9, 1945, indicated the presence of a corpuscular eclipse corresponding to velocities of the order of 450-600 km./sec. Only a few cases were available for which the expected time of occurrence of corpuscular eclipse happened to lie within the daylight hours. It was also found that in a good many cases the observations had not been extended to cover the period when a corpuscular eclipse could be detected; such an effect at about five to six hours before the time of optical eclipse was not expected. But the records of Harang²⁰ (Fig. 1a), S. N. Mitra⁷ (Fig. 1c) and the report of Smith-Rose provide positive evidence that the slower corpuscles responsible for the effect take about three days to travel from the sun to the earth.

A feature of considerable interest is brought out in the observations of S. N. Mitra⁷ (Fig. 1c), which shows the presence of two corpuscular eclipses, at about 2½ hr. and 5 hr. respectively before the time of maximum of the optical eclipse on February 25, 1952. This result indicates that there were two predominating groups of corpuscles on that occasion, one of which had a velocity of about 1,300 km./sec. and started one day earlier on the sun, and the other group a velocity of about 640 km./sec. and started about 2½ days earlier on the sun. S. S. Banerjee *et al.*⁸ obtained the effect due to a corpuscular eclipse at about 2½ hr. earlier than the optical eclipse on the same occasion at Banaras; his records do not extend sufficiently to show the other corpuscular eclipse. It may be mentioned in this connexion that according to the observations of the Solar Observatory, Kodaikanal, there were no solar flares during February 1952, and therefore neither of the corpuscular eclipses could be associated with any flare activity. But marked magnetic and ionospheric disturbances prevailed on February 23, 24 and 25, 1952, no doubt under the influence of corpuscular streams associated with M -regions.

It may be noted that some of the velocities given above are less than the critical velocity of 616 km./sec. required for escape of a particle from the sun's surface (for example, 600 km./sec. required for a three-hour delay); but the reason may be that particles emitted with such velocities may describe very elongated ellipses, which may carry them beyond the neutral point of gravitational attraction between the sun and the earth and thus may enable them to enter the earth's domain. For a velocity slightly smaller than the critical velocity, the path may be widely different from a straight one, and thus it may be greater than the actual sun-earth distance. This may cause considerable reduction of the velocity. In conclusion, the suggestion is made that in future eclipse expeditions the observation of the F_2 -layer of the ionosphere should be started at least seven hours earlier than the moment of totality.

Our thanks are due to Prof. M. N. Saha for his interest.

VASCULAR PLANTS COMMON TO THE ARCTIC AND THE BRITISH ISLES

By DR. NICHOLAS POLUNIN

Gray Herbarium, Harvard University, Cambridge, Mass.

SOME fourteen years ago I published^{1,2} an attempted analysis of "Arctic Plants in the British Isles", which was based on one hand on the existing, but partly outdated, British floras and, on the other, on such vascular plants as were known to occur north of lat. 75° N. Sixty-two species or geographical varieties (subspecies) in the native British flora as then known were recognized as being undoubtedly arctic in their affinities, in the absence of proper criteria for a more adequate computation. Of these, no less than forty were characteristic of open soil or rock crevices, seven more were plants of sea-shores or lake margins (making a total of forty-seven characteristic of open habitats), a further eight were characteristic of other habitats but frequently found in open areas in both regions (making a total of fifty-five which are to be found in open habitats), and only the remaining seven of the sixty-two were

marsh or 'heath' plants usually confined to these or other closed communities. Thus the great majority (75.8 per cent) grew chiefly in the absence of competition and no less than 88.7 per cent are frequently found in at least ecologically 'open' situations both in the north and in the south, while some of the remainder may occasionally be encountered in such habitats in the Arctic.

Apart from more floristic exploration in the British Isles and the Arctic, in both of which a great deal has been accomplished since 1939, the main needs before a more worthy analysis of the situation could be made were (1) a proper or at least 'working' delimitation of the Arctic, (2) a modern flora of the Arctic based on such a delimitation, and (3) an up-to-date British flora. With (1) I have long been concerned and, although far from satisfied with the result, have latterly ventured to publish my suggestions (by special request, "although suspecting that in time increased knowledge of local flora, precipitation, total heat, and the incidence of frosts as well as the combination of wind and cold known as 'windchill' will add solidity to the picture, and knowing full well that increased local knowledge will add to its precision"). The accompanying map indicates the southern boundary of the Arctic and proposed subdivision of the latter for phytogeographical citation into ten sectors (the longitudinal subdivision into low-, middle-, and high-arctic zones cannot yet be indicated). At (2) I have been working off and on since 1940, with the result that I now have virtually completed a "Circumpolar Arctic Flora" (to be published by the Oxford University Press) of all the families, genera and species of vascular plants that are known to reach the Arctic as delimited in (1): a proper critical treatment involving lower taxa will have to await the availability of far more Siberian material than is at present open to the Western world. Prerequisite (3) has recently been covered by the publication of Clapham, Tutin and Warburg's welcome "Flora of the British Isles"⁴, to which should already be added further pertinent species⁵. Consequently, a far more adequately based analysis of the species of vascular plants common to the Arctic and the British Isles can now be made.

Taking in general a rather broad, 'conservative' view of specific limits, I have computed that 874 species of vascular plants are so far known to inhabit the Arctic (according to my largely *ad hoc* delimitation). Of these, 833 are native and 41 appear to be established aliens. Of the latter, 33 occur as natives in the British Isles according to the latest reckoning⁶, as does probably another not recognized therein, 3 more occur in the British Isles as aliens, while at least 3 native arctic species seem to be well-established introductions in Britain. There appears to be only a single recognized arctic alien that is unknown in Britain in anything approaching a wild state, though probably others will be recognized when the northern parts of Siberia, particularly, become better known to Western botanists.

Of the 833 species of native arctic vascular plants at present recognized, no less than 267 occur in the native British flora, in which they consequently form a very substantial 'element' and, in addition, two more used to occur but are now apparently extinct. To arrive at the main figure, occasional compressions have had to be made to get over differences of opinion as to specific limits, especially where insufficient herbarium material was available for practical

Fig. 1. North polar regions, showing proposed delimitation and subdivision of the Arctic

clarification; the result when we add introduced plants is that 309, or more than 35 per cent, of the species of vascular plants so far known to inhabit the Arctic occur also in the British Isles. This excludes supposedly extinct species but includes aliens; even if the latter, too, are excluded, just over 32 per cent of native arctic vascular species are known in the present-day native British flora. Of the remainder, stimulated by news of several recent discoveries, I have selected the fifty which seem to me most likely to be found in the British Isles in the future*. The majority of these are plants of open soil or other habitats where there is little or no competition with other species, and almost all are able to grow in such situations in the Arctic.

It remains to make an analysis, primarily along the lines attempted previously from much less adequate data¹, of the 309 species of vascular plants at present accepted as common to the Arctic and the British Isles. Representing introduced species are all those supposedly transported by man to the regions concerned—whether by the Norsemen many centuries ago or by others quite recently—so long as they appear to have become established in a more or less wild state, and whether introduced to the Arctic or Britain or both. In cases of serious doubt, as, for example, where a normally introduced species could, so far as the habitat or collection-label indicated (or failed to indicate), be considered as perhaps locally native, it has been counted as introduced, so as not to weigh unfairly on the side of the natives. But when a normally introduced species appears to be native in even one place in the Arctic it has been counted as native therein.

The following categories and representations were recognized in this new analysis.

(1) Plants commonly of open soil or rocky, etc., habitats with little or no competition (although humus may be plentiful). (a) Found in all three latitudinal arctic zones and of wide distribution meridionally in the Arctic (occurring in at least 5 of the 10 sectors indicated in the map). Total 47 (all native). (b) Occurring northward at least to the middle-arctic zone, and found in at least 3 sectors (cf. map). Total 23 (all native). (c) Limited to the low-arctic zone or otherwise of restricted distribution in the Arctic. Total 59 (including 25 introductions, namely, 19 introduced in the Arctic, 1 in Britain, and 5 in both).

(2) Plants of sea-shores or lake, etc., margins (including aquatics) with little or no competition. Total 43 (all native).

(3) Plants to be found in open areas but characteristic of closed habitats. Total 80 (including 15 introductions, namely, 13 introduced in the Arctic, 1 in Britain, and 1 in both).

(4) Plants usually restricted to closed habitats. Total 48 (including 2 introductions,

namely, 1 introduced in Britain and 1 in the Arctic).

It is thus seen that, of the species of vascular plants common to the Arctic and the British Isles, a total of 172 or 55.66 per cent are to at least a considerable extent 'open soil' plants or their competition-ecology equivalents, and a further 89 (making a total of 84.46 per cent) are fairly frequently to be found growing in such circumstances. Although these percentages are lower than those formerly computed from a much more limited flora²—as was to be expected particularly in view of the preponderance of open habitats in the Far North—the latter one is only slightly lower. This confirms the earlier suggestion that the majority of British vascular plants which reach high latitudes grow largely where there is little or no competition, while the vast majority of them are fairly frequently to be found in such circumstances—in the south where closed vegetation is the general rule as well as in the Arctic where it is not. Even of the 48 remaining species normally restricted to heathy, marshy, or other closed habitats, a considerable proportion are occasionally to be seen growing in 'open' areas.

Further notes and details will shortly be published in *Watsonia*—including, in line with the policy followed on the previous occasion, lists of the species of plants in each of the above categories.

Radio Emission from the Perseus Cluster

A RADIO source the position of which coincides closely with the cluster of extragalactic nebulae in the constellation of Perseus has been observed by Ryle, Smith and Elsmore¹, by Mills² and by Hanbury Brown and Hazard³. The last-named authors have

Observations with the new Cambridge radio telescope⁴ have been made on a wave-length of 3.7 m. using interferometer apertures of 14 λ and 157 λ. On the assumption that the radio emission was produced by the integrated effect of all the component members of the cluster, the angular distribution of intensity was calculated from optical counts of nebulae in the cluster. For a source having this distribution, the apparent intensity which would be observed with an aperture of 157 λ would be 7 per cent of that obtained with a 14 λ aperture. If, on the other hand, the radiation originated in NGC 1275,

Figure showing the position and limits of error of the radio source obtained with the 157 λ aperture in relation to (a) NGC 1275 and (b) the Perseus cluster as a whole. (Epoch 1950.0)

suggested that the observed radio emission is to be associated with the cluster as a whole, and they have pointed out that on this hypothesis there is an important discrepancy between the average radio emission of the individual galaxies of the cluster and that of nearby galaxies. Baade and Minkowski⁵, on the other hand, have suggested that the radio source should be identified with NGC 1275, one of the members of the cluster. This nebula, like that associated with the intense radio source in Cygnus, is probably another example of two galaxies in collision; the optical spectrum contains lines of high excitation and the structure suggests that a collision has taken place between an elliptical and a spiral nebula.

Experiments to decide which of these two hypotheses is correct are important since they might provide information concerning the radio emission accompanying a collision of this type; alternatively, if the radiation were found to originate in the cluster as a whole, it would have importance in connexion with the relation between the visual and radio magnitudes of extragalactic nebulae.

The angular diameter of the whole visible cluster is approximately 2°, whereas that of NGC 1275 is only 0.7'. Measurements of the angular diameter of the radio source should therefore be important in distinguishing between the two possible interpretations. If the source proved to have small angular size, its association with NGC 1275 might be confirmed by accurate positional measurements.

the intensities observed with the two apertures would be the same to within 1 per cent. The results obtained are summarized as follows:

Aerial spacing	Apparent intensity
14 λ	$16 \times 10^{-26} \text{ W.m.}^{-2} (\text{c/s.})^{-1}$
157 λ	$12 \times 10^{-26} \text{ W.m.}^{-2} (\text{c/s.})^{-1}$

These results show that about 75 per cent of the radiation originates in a source of small angular size; the close agreement between the position obtained with the high resolving power and that of NGC 1275 shown in the figure provides strong confirmation of the identification made by Baade and Minkowski.

The intensity produced by the remaining galaxies of the cluster is approximately $4 \times 10^{-26} \text{ W.m.}^{-2} (\text{c/s.})^{-1}$; this is in good agreement with that derived on the assumption that there is a constant ratio between the optical and radio emission of extragalactic nebulae.

These observations were undertaken as part of a programme of research supported in the Cavendish Laboratory by the Department of Scientific and Industrial Research, to which one of us (J. E. B.) is indebted for a maintenance allowance.

Intensities of Discrete Radio Sources in Cygnus and Cassiopeia at 22.6 Mc/s.

It is important both for the understanding of the nature of the localized radio sources and the determination of interstellar radio absorption to extend the measurement of the spectra of the sources to as low radio-frequencies as possible. Ionospheric transmission sets a limit, but by choosing frequencies not too close to the critical frequency, and restricting observations to days of low ionospheric disturbance, reasonably accurate measurements may be obtained. In this way, we have recently made measurements at a frequency of 22.6 Mc/s. ($\lambda = 13.3$ m.) by means of an interferometer consisting of two aerials spaced in the east-west direction at 20 wave-lengths apart, thus producing lobes in the aerial pattern at intervals of about 3° . Each aerial consists of an array of six full-wave dipoles giving a vertically directed beam of width $\pm 22^\circ$ and $\pm 9^\circ$ in the north-south and east-west directions respectively. The recording apparatus is a simplified form of the type described by Machin, Ryle and Vonberg¹, whereby the receiver is continually switched to a standard noise diode source which is automatically adjusted by a servo-mechanism to equalize the received radiation.

Recordings of the intensity of the discrete radio sources in Cygnus and Cassiopeia were made between June and November 1953. Ionospheric conditions frequently caused violent amplitude fluctuations, and at times there were not only severe decreases of intensity but also increases from the undisturbed value by a factor of two or three. In determining the absolute intensity of the sources, only those records were used where the fluctuations were of negligible amplitude, and this occurred on more than thirty days during the period of observation. The absolute intensities of Cassiopeia and Cygnus were respectively 9.4×10^{-23} and 4.6×10^{-23} watts m.⁻² (c/s.)⁻¹ with an r.m.s. error of less than 20 per cent, excluding a possible systematic error in aerial gain. If the sizes of the sources are taken to be those determined by Hanbury Brown, Jennison and Das Gupta^{2,3} at 125 Mc/s., the brightness temperature of Cassiopeia at 22.6 Mc/s. is about 6×10^6 deg. K. and that of Cygnus about 3×10^6 deg. K.; it is possible that the sources may be more extensive at the lower frequency and the brightness temperature correspondingly reduced.

The values we have obtained at 22.6 Mc/s. have been plotted in Fig. 1, together with the intensities at higher frequencies published by Stanley and Slee⁴, Ryle, Smith and Elmore⁵, Hanbury Brown and Hazard⁶, and Mills⁷, and the results indicate that the intensity continues to increase as the frequency is decreased. The spectrum of Cassiopeia follows a law of intensity proportional to (frequency)^{-1.2}. The spectrum of Cygnus, on the other hand, closely follows the same law as Cassiopeia at higher frequencies but, at low frequency, appears to deviate by about 20 per cent. The accuracy of the measurements of absolute intensity are probably only of this order, but the reality of this deviation can be tested by comparing the more accurate relative values of the intensities of the two sources obtained by those observers who, on their particular frequency of observation, have used their apparatus to measure both sources. These ratios are shown in Table 1, which again indicates that, although at the higher frequencies the ratios of the intensities of Cygnus and Cassiopeia are equal, at the lowest frequency

Fig. 1. Spectra of the discrete sources in Cygnus and Cassiopeia. The straight lines represent the law of intensity $\propto$ (frequency)^{-1.2}. $\circ$, Stanley and Slee (ref. 4) (intensities tabulated by Piddington and Minnett, ref. 13, are plotted); $\times$, Ryle, Smith and Elmore (ref. 5); Δ , Hanbury Brown and Hazard (ref. 6); $+$, Mills (ref. 7); $\square$, present results.

the intensity of Cygnus is reduced by about 20 per cent in comparison with Cassiopeia.

Baade and Minkowski⁸ have recently associated the source in Cassiopeia with unusual nebulous filaments of gas at a range not greater than 500 parsecs; the source in Cygnus appears to be due to the collision of two nebulae and is at a range of 34 megaparsecs on the old distance scale. The source in Cassiopeia is a member of the galactic system, and although close to the galactic equator, it is a near source which shows no evidence of visual obscuration. The Cygnus source is extra-galactic and situated at low galactic latitude near the edge of the 'zone of avoidance', the region in which the numbers of observed extra-galactic nebulae are reduced by visual obscuration. Observations of the 21-cm. line emission^{9,11} also indicate the occurrence of a considerable depth of hydrogen in the ground-state in this direction. If the interstellar gas is appreciably ionized, absorption may be expected at the lower frequencies. As the high-frequency spectra of the two radio sources are similar, and both seem to have their origin in low-density clouds with high internal velocities, it is possible that their emission spectra may be fundamentally the same but that the intensity of Cygnus at 22.6 Mc/s. is reduced by interstellar absorption. Alternatively, part of, or all, the reduction may be characteristic of the spectrum at the source. As it appears unlikely that the slope of the frequency spectrum would increase in magnitude,

Table 1. INTENSITIES OF THE RADIO SOURCES IN CYGNUS AND CASSIOPEIA

Observer	Frequency (Mc/s.)	Intensity in units of 10^{-23} watts m. ⁻² (c/s.) ⁻¹		Ratio of Cygnus/Cassiopeia
		Cassiopeia	Cygnus	
Hanbury Brown and Hazard (ref. 6)	158.5	9.25	5.7	0.62
Ryle, Smith and Elmore (ref. 5)	81.5	23.0	13.5	0.61
Present results	22.6	9.4	4.6	0.49

the 20 per cent intensity reduction of Cygnus is an upper limit to the galactic absorption. The integrated product of path-length times absorption coefficient is consequently not more than 0.2; and as the galactic latitude of Cygnus is 4.9° , the comparatively low absorption is a further confirmation of the findings of Scheuer and Ryle¹² that, if appreciable ionized interstellar gas is present in the galaxy, it is confined within narrow limits to the galactic equator.

Temperature Distribution in an Electrically Heated Filament

THE distribution of temperature in a filament electrically heated *in vacuo* has been studied by several previous authors. The differential equation defining the steady state is:

$$\frac{dT}{dx^2} + \frac{5}{2} a (T_m^4 - T^4) = 0, \quad (1)$$

in which T is the temperature at a distance x from one of the ends, T_m is the value to which the temperature T_l at the centre tends as the length $2l$ of the filament is increased indefinitely, keeping the heating current the same, and a is a constant determined by the cross-section of the filament, its thermal conductivity and the emissivity of its surface. Using the boundary conditions $T = \theta$ when $x = 0$, and $dT/dx = 0$ when $x = l$, one obtains¹

$$x = \int_0^T [\delta a T_m^4 (T_l - T) - a (T_l^4 - T^4)]^{-\frac{1}{2}} dT, \quad (2)$$

the value of T_l occurring in (1) being determined by the condition that, when the upper limit of the integral is made equal to T_l , x should become l .

In a recent paper² it was shown that though the integral cannot be evaluated directly, it can be expanded as a convergent power series. The filament can be divided for this purpose into two distinct regions, region A comprising a certain length near the middle, and region B outside it, the power series referred to being different in the two regions.

Now, denoting $T_m - T$ by Δ , it can be shown that:

$$\Delta \exp f(\Delta) = \exp \pm x\sqrt{A} \quad (3)$$

are solutions of (1), where

$$A = 10 a T_m^3 \quad (4)$$

and

$$f(\Delta) = \frac{1}{2} \frac{\Delta}{T_m} + \frac{1}{16} \frac{\Delta^2}{T_m^2} - \frac{1}{240} \frac{\Delta^3}{T_m^3} - \dots \quad (5)$$

The effect of the finite temperature coefficient of the thermal conductivity, and of the other constants, can also be taken into account by replacing the factors $\frac{1}{2}$, $\frac{1}{16}$, $-\frac{1}{240}$, ... by A_1 , A_2 , A_3 , ... which can be calculated. For a tungsten filament with $T_m = 2,400^\circ \text{K}$, $A_1 = 0.75$, and the other A 's are much smaller.

In the region where $\exp f(\Delta)$ is close to unity, a general solution for the finite filament can be obtained by suitably combining the two particular solutions given by (3). The corresponding two terms in the general solution are obviously such that one of them increases rapidly and the other decreases rapidly as we move away from the centre of the filament. If $T_m - T_l$ is sufficiently small, the latter term may become negligible in comparison with the former, while Δ still remains small enough to permit our combining the two particular solutions. When this has happened, the need to keep $\exp f(\Delta)$ close to unity disappears. We thus obtain a *practical* general solution that is applicable over the whole length of the filament, namely:

$$\begin{aligned} \Delta \exp f(\Delta) &= \Delta_0 \exp f(\Delta_0) [\exp -x\sqrt{A} + \exp \{- (2l-x)\sqrt{A}\}] \\ &= \Delta_0 \exp f(\Delta_0) \exp -l\sqrt{A} (\exp q\sqrt{A} + \exp -q\sqrt{A}), \end{aligned} \quad (6)$$

where $\Delta_0 = T_m - \theta$, and $q = l - x$ is the distance measured from the centre.

Now for a filament for which $T_m - T_l$ is small in comparison with T_m , which we shall refer to for convenience as a 'long' filament, the limit of the A -region is given by $\Delta_0 \sim 3(T_m - T_l)$. At this point it is found that the ratio of the second term inside the brackets in (6) to the first term has decreased to about $\exp(-3.6)$, that is, below 3 per cent. Taking for convenience this fraction, namely 0.03, as small in comparison with unity, we can readily investigate how small $T_m - T_l$ should be in comparison with T_m in order that (6) may hold over the whole length of the filament to at least this degree of accuracy.

It may appear at first sight that the criterion for our being able to combine the two particular solutions, namely, that $\exp f(\Delta)$ should be close to unity, will become increasingly difficult to satisfy as Δ increases. But actually, owing to the disparity in the magnitudes of the two terms to be combined, which increases rapidly as one moves away from the centre, the working criterion becomes $f(T_m - T_l) < 0.03$, or $(T_m - T_l) < 0.04 T_m$. When this is secured, (6) will fit with observation to a much closer accuracy than 3 per cent, the accuracy increasing rapidly as one moves away from the centre of the filament.

The results obtained earlier for such a filament, on the basis of the series-expansion of the integral—namely, the parabolic variation of temperature in the A -region, the closeness of the distribution outside the A -region to that of a similar infinitely long filament heated by the same current and the logarithmic distribution at the top of this range—all come out as special cases of (6).

By putting $x = l$ in (6), one obtains a useful relation for the temperature T_l at the centre of a long filament, as a function of its length, namely:

$$T_l = T_m - 2\Delta_0 \exp f(\Delta_0) \times \exp -l\sqrt{A}, \quad (7)$$

in view of which (6) may also be written in the convenient form,

$$\Delta \exp f(\Delta) = \frac{1}{2} (T_m - T_l) (\exp q\sqrt{A} + \exp -q\sqrt{A}), \quad (8)$$

which is applicable over the whole length of a long filament.

A New Technique for Investigating Surface Flow in Metal-working Processes

DURING the plastic deformation of metals in shaping processes, there is relative movement between the flowing metal and the tools. An attempt was made by Siebel and Osenberg¹ to deduce this relative movement by noting the distortion of a grid scribed

to the first, and a curved scratch is produced. The final shape is like that of a fish-hook. Fig. 1 shows stages in the development of scratches through the arc of contact. The specimen was prepared by interrupting the rolling process and removing the strip for examination.

A preliminary investigation based on the measurement of surface scratches has led to several conclusions regarding the rolling process.

(1) The projected length of scratch in the rolling direction is close to the length predicted by a simple theory based on the assumption that the deformation is homogeneous.

(2) The neutral position, which is related to the frictional conditions in rolling, can be directly observed.

(3) The spread of elements in the surface can be measured by observation of the length of the scratch projected in the lateral direction.

(4) Since the direction of the growing end of a scratch within the region of contact coincides with the direction of the frictional force at that point, maps of frictional force direction in the region of contact may be constructed. In theories of rolling it has always been assumed that the frictional forces are parallel to the rolling direction. Observations have shown that even with small lateral spread (less than 1 per cent) this is far from being the case.

Fig. 1. Surface scratches on partly rolled copper strip (3 in. wide $\times$ 0.2 in. thick: reduction, 15 per cent)
(a) Between entry and neutral position; (b) near neutral position; (c) at exit. $\times$ 150

on the surface of strip before further rolling. The accuracy was not high, however, and the method yielded little information on surface flow.

It occurred to us that small projections on the surface of the rolls or tool faces might give rise to ploughed tracks on the surface of the metal undergoing deformation, and that such markings might provide illuminating evidence regarding the relative movement. We have observed that tracks or surface scratches are, in fact, produced by the adventitious minute projections normally present on rolls and platens. These surface scratches provide a valuable means of investigating the topography of surface flow during deformation.

When a metal strip is reduced in thickness by passing it between cylindrical rolls, its speed, on entering the zone of deformation, is less than that of the roll periphery. The strip is accelerated until, at some 'neutral position' within the region of contact, roll and strip surfaces are moving with the same velocity, and the strip finally emerges moving more rapidly than the rolls. The relative movement which takes place generates the surface scratches mentioned above. Spreading in the lateral direction adds a second component of relative velocity at right angles

Further work using the technique described here is in progress.

Refractive Index of Concentrated Protein Solutions

AN accurate knowledge of the specific refraction increment α , or dn/dc , of proteins is important in measurements which involve the use of the ultracentrifuge, electrophoresis and light-scattering. Recently, it has become important in connexion with cytological methods of refractometry¹ and mass determination² of living cells. The refraction increment has hitherto usually been measured only at rather low concentrations. The highest concentration reported seems to be by Howard³ in 1920, who found that the variation of refractive index with concentration of haemoglobin was linear up to about 17 per

cent. Armstrong *et al.*⁴ found that α for crystalline serum albumin was constant up to a concentration of 14.6 per cent. Since in cytology considerably higher concentrations may be encountered, and it is well known that the refractive indices of some substances, for example sugars, do not vary quite linearly with concentration, we have measured the refractive indices of bovine serum albumin solutions up to concentrations exceeding 50 per cent. In order to avoid the difficulties associated with the measurement of protein concentrations by dry-weight or nitrogen determinations, we have obtained a factor proportional to the concentration by measuring the optical density at 278 m μ , using a Hilger 'Uvispek' ultra-violet spectrophotometer. Deviations from the Beer-Lambert law were avoided by diluting all samples accurately by different amounts to give approximately the same final optical density. The final concentration was about 0.2 per cent in each case, giving optical densities between 1.0 and 1.3 for a 1-cm. path-length.

Fig. 1 shows the results obtained with non-crystalline bovine serum albumin fraction V (Armour) dissolved in distilled water. Refractive indices were measured at 20° C. in an Abbe type refractometer at λ 5780 Å. Optical density values were converted to protein concentration by using the published figure⁵ of 6.6 for $E(1\%, 1 \text{ cm.})$. The probable errors increase with concentration because of the difficulty in manipulating and measuring very viscous solutions. Nevertheless, the refractive index increases linearly with concentration up to at least 45 per cent. The value of α obtained was 0.00182. This is in reasonably good agreement with values found by others^{4,6}; but in view of possible uncertainties in the extinction coefficient and hence in the protein concentrations, no claims for high accuracy are made. The main purpose of this investigation was to determine whether α remained constant with increasing concentration.

Excellent linearity has also been obtained in the case of peptone (Evans bacteriological) up to 50 per cent concentration. The value for α in this case was

Fig. 1. Variation of refractive index (n) of bovine serum albumin solution with concentration (C)

0.00174, but this was based on the weight of peptone as supplied. Since the moisture content of this product is approximately 5 per cent, the corrected value for α would be 0.00183, again in good agreement with values obtained for proteins.

These results suggest that: (1) unlike the sugars, at least some proteins and protein derivatives have constant values for α over a wide range of concentrations; (2) the breakdown of proteins into components of lower molecular weight has very little effect on α . This confirms the observation of Robertson⁷ that complete digestion of sodium caseinate by trypsin had no detectable effect on the refractive index. We have also been unable to detect any change in refractive index during the digestion of bovine serum albumin by pepsin.

We wish to thank Dr. P. W. Kent for the loan of the refractometer. This work was assisted by a grant from the Medical Research Council to one of us (S. T.) and by grants from the Royal Society and the Rockefeller Foundation.

Cobalt as a Carcinogen

The effects of various metals on living cells in tissue culture are being investigated in this Laboratory, and a non-lethal disturbance of normal mitosis produced in chick fibroblasts by cobalt (as chloride) has already been reported¹. This effect, which is characterized by the persistence of the nucleoli in mitotic cells throughout prophase into meta-, ana- and telo-phase, appears to be specific for cobalt, inasmuch as no comparable effect is produced by nickel, iron, zinc, chromium, manganese or beryllium in sublethal concentrations.

The cobalt is added to give a concentration of approximately 10×10^{-6} gm./ml. cobalt, to ordinary hanging-drop cultures after 24-hr. growth, when mitosis is approaching its peak; under these conditions, the effect reaches a maximum some 10-14 hr. later, when almost all dividing cells display persistent nucleoli. This type of culture begins to deteriorate after about 48 hr. unless the tissue is transplanted, and hence the prolonged action of cobalt on the cells cannot be studied. With the Maximow technique (double-cover slip method), in which the tissue can be washed and replenished with fresh medium without disturbing the cells, it is possible to prolong the life of the culture so that by adding the cobalt at some convenient point in the procedure, the effect can be observed over a longer period.

Some preliminary experiments on these lines produced at 72 hr. many giant cells in metaphase, each carrying one or more large cytoplasmic nucleoli.

Observation of such living cells in the warm chamber by phase-contrast illumination showed that they became reconstructed into mononucleate cells without any division taking place; the cell retains one or more large cytoplasmic nucleoli. These persistent cytoplasmic nucleoli are clearly demonstrated when the cultures are fixed in methyl alcohol or acetic-alcohol and stained with methyl green-pyronin. Stained by this method, the giant metaphase cells also show many pyronin-staining granules in the cytoplasm, which would appear to indicate an accumulation of ribonucleic acid.

These cellular changes produced *in vitro* were not lethal, and it seemed interesting to see what would happen if cobalt was allowed to act locally on an animal tissue *in vivo*. Accordingly, some pure 400-mesh cobalt powder was mixed with fowl serum, and a quantity of 0.028 gm. cobalt in 0.4 ml. serum was injected into the thigh muscles of rats 2-3 months old of the hooded strain. Ten male and ten female rats were so treated and a further ten male and ten female animals of the same strain and age were similarly injected with fowl serum only. There was little or no reaction immediately after the injection, and nothing was observed for some five months, when two male rats began to develop tumours at the site of injection. One month later, these tumours measured approximately 3 cm. $\times$ 3 cm. and at autopsy were found to be malignant neoplasms. I am indebted to Dr. A. Glücksmann of this Laboratory for the following report on the histological characteristics. One tumour was a highly cellular and fairly undifferentiated rhabdo-myo-fibrosarcoma and the other a cellular rhabdo-myo-fibrosarcoma with slightly better differentiation. The first one produced a definite lymph node metastasis. Sections of these tumours stained with methyl green-pyronin showed persistent nucleoli in a few of the mitotic cells. In addition to these two tumours in males, at six months one female began to show a tumour at the site of injection; this is still growing and is now approximately 3 cm. in diameter. At the present time—seven months from injection of the cobalt—two more females have tiny nodules at the site of injection.

Further experiments are in progress to repeat these observations and also to extend the work to other metals. The neoplastic process evoked may not be related in any way to the cytological effects observed *in vitro*. The fact that nickel can produce rat tumours¹ and yet does not cause the persistent nucleolar effect *in vitro* would seem to argue against any such relationship.

This work is being done with the support of the British Empire Cancer Campaign.

Note added in proof. The tumour in the female rat reached a size of approximately 4 cm. $\times$ 3 cm. at 7½ months, and histological examination by Dr. A. Glücksmann showed it to be a moderately differentiated fibrosarcoma with giant cell formation. This tumour was transplanted into other rats of the same strain, and so far 5 'takes' out of 20 have occurred. One of the nodules mentioned in a female rat developed into a cellular fibrosarcoma, and a further large tumour is growing in another male rat.

Soluble Feather Keratin

The stability of feather keratin in the solid state is due to cross-linking of the polypeptide chains by hydrogen bonds, disulphide linkages and electrostatic forces, and under conditions where these bonds are broken solutions of the protein are obtained. The molecular characteristics of the particles in solution are of interest because of their relevance to the interpretation of the data obtained by the diffraction and scatter of X-rays by solid keratin, and the interaction of the particles in solution is relevant to the problem of the manufacture of fibres from the regenerated keratin. I wish to present here data of this sort for soluble feather keratin and in particular to identify the keratin monomer, which it was considered would be a particle in which bonding between the polypeptide chains due to hydrogen bonds, disulphide linkages and electrostatic attraction was absent.

80-85 per cent of chicken feather keratin dissolves in 10 M urea, 0.1 M bisulphite, 0.05 M phosphate (pH 8.5) after 18 hr. extraction at 40° C. The soluble protein, SH-keratin, remains in solution when the urea concentration is reduced to 5 M, and in this solution the cysteine-cystine ratio of the keratin is a function of the pH (Table 1).

When these solutions of SH-keratin are dialysed against water, a solution, or, when the protein concentration is greater than about 3 per cent, a gel, is produced. The solution or gel can be dried by sublimation to give a solid which contains no cysteine and 90 per cent of the cystine in the original feather; this is taken as evidence that few thio-ether or other stable cross-linkages are formed from the cystine and bisulphite. Treatment of this solid with performic acid gives a solution from which a protein (cysteic acid-keratin) can be recovered that contains neither cystine nor cysteine. In 0.05 M sodium carbonate, cysteic acid-keratin migrates with a single boundary on electrophoresis.

The graphs relating the osmotic pressure-concentration ratio to the concentration of SH-keratin in 5 M urea, 0.1 M bisulphite, 0.05 M phosphate, at pH 8 and at pH 8.5, and of cysteic acid-keratin in this solvent at pH 8.5, extrapolate with different slopes to the same value at zero concentration corresponding to a molecular weight of 10,000. Cysteic acid-keratin exhibits ideal behaviour in the concentration range 0.1 per cent, but SH-keratin deviates from ideal behaviour, indicating that association occurs with increasing concentration. In Table 1 the extent of the association is given as the ratio of the values of the osmotic pressure-concentration ratio at zero and 1 per cent concentration.

Measurements of light-scattering give confirmation of the association of SH-keratin at pH 8.5 and give a value of the weight average molecular weight of 11,000 in infinitely dilute solution.

From the intrinsic viscosity the axial ratio of SH-keratin in 5 M urea, 0.1 M bisulphite, 0.05 M phosphate (pH 8.5) and of cysteic acid-keratin in 5 M urea, 0.1 M sodium chloride, 0.05 M phosphate (pH 8) is 13 (calculated from Simha's equation², assuming that the proteins are unsolvated and are prolate ellipsoids). The specific viscosity of cysteic acid-keratin is independent of concentration in the range 0.1 per cent, but that of SH-keratin increases with increasing concentration; this is taken as evidence for the formation of increasingly asymmetrical particles by association.

Table 1. OSMOTIC PRESSURE AND CYSTEINE-CYSTEINE CONTENT OF KERATIN IN UREA SOLUTION

The numbers of —SH and —S—S— groups are calculated on the basis of each monomer having a molecular weight of 10,000 and six potential SH groups. The molecular weight is obtained from the value of P/C at zero concentration

Solute	Solvent	pH	Mol. wt.	$\frac{*P/C: C=0}{P/C: C=1}$	No. of —SH groups in monomer	No. of S—S groups in monomer
SH-Keratin	5 M urea	8	10,200	1.08	5.2	0.4
SH-Keratin	0.1 M bisulphite	8.5	9,500	1.45	2.2	1.9
	0.05 M phosphate					
	5 M urea					
SH-Keratin	0.1 M bisulphite	8.5	9,500	1.58	2.4	1.8
	0.05 M phosphate					
	0.2 M ethanol					
SH-Keratin	5 M urea	8.5	9,700	1.00	—	—
	0.1 M bisulphite					
	0.05 M phosphate					
Cysteic acid-keratin	0.2 M mercapto-ethanol	8.5	10,200	1	0	0
	5 M urea					
	0.1 M bisulphite					

* P, osmotic pressure; C, concentration

SH-keratin in urea, bisulphite, phosphate (pH 8.5), and cysteic acid-keratin in urea, sodium chloride, phosphate (pH 6) each sediment with a single symmetrical boundary on ultracentrifugation in the synthetic boundary cell of Pickels, Harrington and Schachman². Corrected for water at 20° as solvent, the sedimentation constant of each in infinitely dilute solution is 1.05 Svedberg units. This value, with the frictional ratio obtained from the viscosity data, gives the molecular weight as 10,100.

If the cysteine residues are equally distributed among the polypeptide chains of SH-keratin, then each particle of molecular weight 10,000 has potentially six SH groups. In Table 1 are given the number of —SH and —S—S— groups in each particle of keratin. Consideration of these results, together with the degrees of association that the osmotic pressure and light-scattering measurements reveal, suggests that the association only occurs when there are present both —SH and —S—S— groups. The addition of *B*-mercaptoethanol to a solution of SH-keratin in urea, bisulphite, phosphate at pH 8.5 decreases the degree of the association, whereas the addition of ethanol does not (Table 1). It is therefore possible that, with increasing concentration of SH-keratin, intermolecular —S—S— bonds form at the expense of intramolecular bonds through the intermediary action of the —SH groups³. The —S—S— bonds in SH-keratin in infinitely dilute solution are intramolecular, since the protein under these conditions has the same molecular weight as cysteic acid-keratin, which contains no cystine.

Further osmotic pressure measurements have shown that the molecular weight of keratin in infinitely dilute solution is constant in the range of urea concentration 10–5 M, of ionic strength 0.17–0.64, and for preparations which contain 0.2–9 gm. mol. cystine per 10,000 gm. keratin. It is therefore probable that under these conditions cross-linking of the polypeptide chains is absent and that we are indeed measuring the molecular size of the monomer.

I wish to thank Prof. K. J. Mysels for his advice during this work, which was done during the tenure of the Rubberst Fellowship of the University of Southern California and a Fulbright travel grant. The ultracentrifugation was done at the Sloan-Kettering Institute for Cancer Research, New York, and I am indebted to Dr. Mary L. Petermann for her hospitality and instruction. Full details of these

experiments will be published in the *Biochemical Journal*.

Physical State of Deoxyribonucleic Acid in Rat Thymus Homogenates

In a recent communication, Anderson¹ has shown that when the thymus of the freshly killed rat is homogenized and then dissolved in *M* sodium chloride, extremely viscous solutions are obtained. It is clear that the high viscosity is primarily due to the deoxyribonucleic acid present, but it is much greater than that of solutions containing the same amount of deoxyribonucleic acid isolated by the usual technique. To explain this discrepancy, Anderson suggested that in freshly prepared tissue homogenates deoxyribonucleic acid has a much higher molecular weight than the chemically isolated substance. This explanation is valid only if the deoxyribonucleic acid is molecularly dispersed in the tissue homogenates and does not interact with any other compound present. Using rat thymus homogenized in 0.14 M sodium chloride, filtered through nylon cloth and then diluted with an equal volume of 2 M sodium chloride, evidence has been obtained which suggests that the deoxyribonucleic acid is probably present in the form of aggregates in which nucleic acid molecules are cross-linked by protein bridges.

The homogenates, containing 0.020–0.003 per cent of deoxyribonucleic acid, were centrifuged at 80,000 *g* for five minutes. In all cases a clear non-viscous supernatant was obtained which could easily be poured off from the small gel-like pellet of sediment. Tests using the Dische diphenylamine reaction² showed that no deoxyribose was left in the supernatants. This high rate of sedimentation means that either aggregates are present or that the molecular weight of the deoxyribonucleic acid is far greater even than that suggested by Anderson.

The original homogenate in 0.14 *M* sodium chloride was centrifuged at low speed to remove debris and the insoluble deoxyribonucleoprotein, and the concentration of protein left in the supernatant was determined using the Mehl biuret method³. This was then compared with the concentration of protein in the supernatants obtained by centrifuging the *M* sodium chloride solutions at high speed as described above. It was found that the amounts of protein were the same to within 2 per cent. Since complete dissociation of the deoxyribonucleoprotein would have increased the protein concentration by 20 per cent, it can be concluded that either most of the histone has sedimented along with the deoxyribonucleic acid and therefore that in *M* sodium chloride dissociation is far from complete, or that any histone liberated by dissociation of the nucleoprotein has been replaced by other proteins.

Further evidence that the protein associated with the nucleic acid contributes to the viscosity has been obtained by hydrolysing it with chymotrypsin. Three solutions of the homogenate in *M* sodium chloride, one containing chymotrypsin and one deoxyribonuclease, were incubated at 25° C. for 16 hr. The presence of deoxyribonuclease reduced the viscosity to one-quarter of that of the solution containing no added enzyme, while the presence of chymotrypsin reduced the viscosity to one-half.

Viscosity measurements with the *M* sodium chloride solutions are unsatisfactory, first because of their inhomogeneity and secondly because they exhibit thixotropy. Chymotrypsin and deoxyribonuclease greatly reduce the thixotropic nature of the solutions. The viscosities of the solutions treated with enzymes have been compared with the viscosity of the untreated solution after this has been run through the viscometer a sufficient number of times for the rate of flow to become reasonably constant. When compared with the viscosity of an untreated solution which has been run several times through the viscometer, the effect of X-ray irradiation roughly parallels the effect on solutions of isolated nucleic acid⁴. 80 r. produces a barely significant fall in viscosity, 800 r. an appreciable decrease, and 8,000 r. a marked decrease.

Since deoxyribonucleic acid is still associated with protein and the protein contributes to the viscosity of this system, the viscosities cannot be used directly for determining the molecular weight of the nucleic acid.

I thank Prof. J. A. V. Butler for his interest and advice during the course of this work. This investigation has been supported by grants to the Royal Cancer Hospital and Chester Beatty Research Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

Mutagenic Activity of Ethylenimine Picrate

RESEARCHES carried out during the past few years to investigate the precise mechanism of action of nitrogen mustards and related compounds suggest the

primary importance of the $\begin{array}{c} \text{CH}_3 \\ | \\ \text{—N—} \\ | \\ \text{CH}_3 \end{array}$ group, which

appears in the molecule of nitrogen mustard, when in aqueous solution, through an intramolecular cyclization process:

Nitrogen mustard-like actions have been demonstrated in monofunctional compounds containing either a preformed ethylenimic ring or capable of forming it, and in ethylenimine itself¹⁻⁴.

On the other hand, Goldacre, Loveless and Ross⁵ suggest that the presence of at least two functional groups in the molecule of mustard and related compounds is required to permit the molecule to react at two distinct points situated either on a single one or on two contiguous protein chains. There was therefore the possibility that cross-linkage could play a primary part in the mechanism of action of nitrogen mustards and related compounds.

In order to evaluate the importance of a single ethylenimic group for the inhibition of aerobic glycolysis in neoplastic tissues, I began studying the action of ethylenimine picrate (kindly prepared by Simes Research Dept., Milan) during 1951. This substance was chosen from among several possible monoethylenimic compounds because of its relatively higher stability.

Tests carried out, according to the Warburg technique, demonstrated that the inhibition-rates of Rous sarcoma and benzopyrene sarcoma glycolysis obtained by ethylenimine picrate were comparable to those obtained by methyl-bis(2-chloroethyl) amine, while inhibition obtained by picric acid is small⁶.

It therefore became clear that the presence of a single ethylenimic group was sufficient to permit an inhibition-rate of aerobic glycolysis in tumour cells comparable to that produced by bifunctional nitrogen mustards.

Consequently, it appears that, contrary to the hypothesis of cross-linkage, the presence of two or more functional groups is not required for a strong inhibition of neoplastic cell glycolysis.

Extending our researches on the mustard-like properties of ethylenimine picrate, we carried out investigations in *Drosophila melanogaster* in order to determine whether that substance has mutagenic activity.

The rate of mutation was estimated by the incidence of sex-linked lethals detected by the *ClB* test. The substance was mixed with the food of the larvae in a concentration of 1×10^{-4} . The emerging ♂♂ were treated again by spraying the substance in a concentration of 1×10^{-3} for 8–10 min. and then mated to fresh ♀♀ virgin *ClB*.

The results obtained (see accompanying table) indicate that, at the concentration employed, ethyl-

Ethylennimine picrate	526	10	1.9
Picric acid	520	1	0.18
Controls	511	0	0

ethimine picrate increases the sex-linked lethal mutation-rate quite significantly, while picric acid does not. Dubious, probably negative, data were obtained also by Auerbach and Robson⁹ employing picric acid.

The demonstration of the mutagenic activity of ethylennimine picrate, together with the demonstration of its inhibitory action on aerobic glycolysis in neoplastic tissues, confirms the importance of the ethylennimine ring in the mechanism of action of nitrogen mustards and ethylennimine compounds, and affords additional evidence in favour of the assumption that the biological activity of mustards and ethylennimine compounds is not essentially due to the cross-linkage mechanism.

Thanks are due to Prof. G. Montalenti for his many helpful suggestions, and to Profs. R. Dohrn and G. Montalenti for their kind hospitality.

Denitrification of Nitrite by a Species of *Achromobacter*

THE effect of oxygen on the process of denitrification continues to be a subject of research, and it may, therefore, be of interest to record some observations made in the University of Melbourne with a species of *Achromobacter*. The organism, which was isolated from soil, reduced nitrite but not nitrate to nitrogen gas.

The organisms were harvested, after incubation for 48 hr. at 25° C., from the surface of a medium which contained: 'Difco' peptone, 10 gm.; 'Difco' yeast extract, 5 gm.; sodium chloride, 5 gm.; agar, 20 gm.; tap water, 1 litre; sodium nitrite (when supplied), 2 gm. The pH of this medium was between 6.8 and 7.2. Anaerobic incubation was carried out under nitrogen or hydrogen in anaerobic jars.

After harvesting, the cells were washed twice and suspended in M/15 phosphate buffer, pH 8. Borate buffer was not used because the nitrite reduction-rate was lower, although it was found that the oxygen absorption on sodium lactate remained unchanged. Cell suspensions obtained in different conditions were adjusted to the same turbidity for comparison of activity. The activity of cell suspensions was expressed as the rate of reduction of sodium nitrite in p.p.m./hr.

Table 1

Conditions of growth	Rate of reduction of sodium nitrite
Aerobic with sodium nitrite	180 p.p.m./hr.
Aerobic, no sodium nitrite	180 "
Anaerobic (hydrogen), with sodium nitrite	1,080 "
Anaerobic (hydrogen), no sodium nitrite	600 "
Anaerobic (nitrogen), with sodium nitrite	1,140 "
Anaerobic (nitrogen), no sodium nitrite	840 "

These rates were determined by following the disappearance of nitrite from the suspensions with sodium lactate, in excess, as the substrate. Suspensions were placed in a constant-temperature bath at 25° C. and were rendered anaerobic by the passage of a stream of nitrogen gas. Nitrite was estimated colorimetrically by the sulphanilic acid- α -naphthylamine method. Nitrite was added to give an initial concentration of about 200 p.p.m., and this initial concentration was estimated.

Table 1 shows the effect of the presence and absence of oxygen on cultures growing with and without nitrite.

These results indicated that the absence of oxygen was a more important factor than the presence of nitrite in the production of highly active cells. Under anaerobic conditions, growth was very slight; but highly active cells could be produced in good yields if a period of anaerobic growth followed an initial aerobic growth. Anaerobic incubation of washed suspensions of cells grown aerobically did not result in increased activity.

A pronounced reduction of 'nitritase' activity was found in media rendered deficient in iron, and the addition of 0.5 p.p.m. of iron, supplied as ferrous sulphate, resulted in cells of normal activity. Owing to the use of solid media, the iron requirement is not accurately known.

Spectroscopic examination of cell suspensions of widely different 'nitritase' activity did not show any relation between the intensity of cytochrome bands and the degree of activity.

The rate of reduction of nitrite did not differ when the reaction was carried out under hydrogen and nitrogen. It therefore did not appear likely that hydrogenase was involved.

Some inhibitor studies were made both with whole cells and with cell-free extracts which were prepared by shaking heavy suspensions with Ballotini beads. The cell debris was removed by centrifugation. The results given in Table 2 are regarded as an initial

Table 2

Inhibitor	Concentration	Preparation	Inhibition
Potassium cyanide	M/10,000	whole cells	73
Potassium cyanide	M/1,000	whole cells	100
Potassium cyanide	M/1,000	extract	85
Hydroxylamine	M/500	whole cells	50
Hydroxylamine	M/500	extract	90-100
Sodium azide	M/500	whole cells (18 hr. exposed)	40
Sodium azide	M/200	extract	73
8-Hydroxyquinoline	M/1,000	whole cells	inhibited and partly reversed by light
Carbon monoxide	qualitative	whole cells	inhibited
Hydrogen sulphide	qualitative	whole cells	inhibited
Copper sulphate	M/1,000	whole cells	99
Silver nitrate	M/1,000	whole cells	96
Phenylmercuric acetate	M/2,500	whole cells	84
Phenylmercuric acetate	M/5,000	extract	80-100
m-Amino p-hydroxy-phenylarsenoxide	M/500	whole cells	93
m-Amino p-hydroxy-phenylarsenoxide	M/1,000	extract	85

survey only. The inhibiting compounds have not been tested over a range of concentrations. Differences have been found in the behaviour of whole cells and extracts. Evidence was also found that the pH optimum of cell extracts was nearer pH 7 than 8. It should be noted that azide interferes with the colorimetric estimation of nitrite in such a way as to give lower than actual inhibition figures. To avoid this difficulty, the percentage inhibition for azide with a cell extract was derived from the measurement of nitrogen production manometrically. The results quoted are the percentage inhibition of the rate of nitrite reduction.

Inhibition by the last two compounds was relieved by the addition of thioglycolic acid. Tryparamide did not inhibit. It is possible that a part of the enzyme system involves an active sulphhydryl group which is produced under anaerobic conditions. This may not be specifically related to the 'nitritase' system, since an increased activity followed anaerobic growth in the absence of nitrite.

Effect of DDT on the Metabolism of Khapli Wheat Seedlings

JOHNSON¹ reported that DDT (dichlorodiphenyl-trichloroethane) affected the metabolism of Khapli wheat so that the seedling leaves became susceptible to a race of *Puccinia graminis* var. *tritici* to which they are normally resistant. The response to DDT was highly specific, as only one other of the resistant wheats tested (Arnautka) showed any indication of susceptibility consequent on spraying.

To determine the specific nature of the response of Khapli wheat leaves to DDT, alcoholic extracts were obtained from DDT-treated and non-treated leaves, 2, 6, 9 and 14 days after treatment. The extracts were concentrated *in vacuo* and, after a short period of storage in toluene, they were chromatographed using *n*-butanol-formic acid-water mixture as used by Wiggins and Howarth². A visual comparison of the spots on the chromatograph revealed a marked change, as a consequence of the leaf being sprayed with DDT solution, in the con-

centration of amino-acids present in sufficient quantity to be detected by 0.1 per cent ninhydrin. Whenever an amino-acid is present in both the extract from the control and the treated leaves, it is present in greater amount in the latter.

Preliminary results with the chromatography of the simple sugars present in the alcoholic extracts reveal that they also are present in greater quantities in the DDT-treated leaves than in the non-treated leaves.

This study is part of an attempt to determine the nature of rust resistance. Evidently the DDT alters the metabolism in such a way that free amino-acids and simple sugars accumulate in the leaf. The effect may be due to an inhibition of synthesis of proteins and carbohydrates. However, the dry weight of the treated seedling leaf increases more rapidly than does that of the non-treated leaf (see Fig. 1). This would suggest that certain substances that normally are transported during the ontogeny of the leaf are not translocated from the treated seedling leaf. In any event, the observations recorded here prove that DDT extensively alters the metabolism of the Khapli wheat seedling. Further study should reveal which, if any, of these alterations are responsible for the increase in susceptibility of the seedling.

Development of the Syncytial Endosperm of *Cocos nucifera*

DUTT¹ has recently summarized her investigations on nuclear behaviour in the developing endosperm of *Cocos nucifera*. Several of her observations are at variance with statements we have previously made^{2,3} and with some of our more recent findings⁴. Since these divergent opinions arise in part from a difference in terminology and in part from misinterpretations of the anatomical structure of the coconut, we wish to present several points to clarify this matter.

Following fertilization, the embryo sac of *Cocos* enlarges rapidly and becomes filled with a clear watery fluid (milk) in which large amoeboid nuclei and fine cytoplasmic particles are suspended. This milk will be referred to as the 'liquid syncytium'. Dutt has not been able to detect free nuclei in this liquid syncytium in the early stages of its development; but they may be easily demonstrated by centrifuging the milk and examining the sediment. Since they are widely dispersed in the liquid they might easily be overlooked in unconcentrated milk. After fertilization, and until the fruit reaches an overall length of approximately 150 mm., an examination of the sac cavity reveals that its boundary is composed of a closely packed layer of isodiametric cells which represents the specialized wall of the inner integument. According to Quisumbing and Julian⁵, the nucellus is digested prior to fertilization, and therefore this specialized cell layer probably represents an integumentary tapetum or endothelium. The endothelium is in direct contact with the milk and there is no cellular endosperm present at this stage. We have previously referred to this layer as

Fig. 1. The effect of DDT, during ontogeny, on the dry weight of the seedling leaf of Khapli wheat

the nucellus under the mistaken impression that this tissue was persistent. As the fruit reaches an overall length of approximately 100 mm. a number of large spherical cells suddenly appear suspended in the liquid syncytium. These cells, which may range from 50 to 300 μ in diameter, show varying numbers of nuclei (1-40). Our observations indicate that these cells, or endosperm vesicles, are formed in the liquid syncytium by the coalescence of cytoplasmic particles around nuclei or groups of nuclei which are floating free in the milk. Dutt has not mentioned these endosperm vesicles.

At a later stage when the fruit is approximately 150 mm. in length these endosperm vesicles and the free nuclei of the liquid syncytium commence to settle out of the milk and attach themselves to the surface of the endothelium. This deposition of vesicles and free nuclei commences at the lower end of the embryo sac cavity and progresses upward around the walls of the sac, thus forming a gelatinous syncytium in which the nuclei are very closely packed. This gelatinous mass of nuclei and cytoplasm soon becomes cellular, forming the meristem which develops the solid endosperm or familiar coconut meat. Dutt states that this meristem develops first at the micropylar end of the sac cavity and creeps progressively over the face of the endocarp, finally covering the entire wall of the cavity. She is apparently under the impression that the micropyle is located at the lower end of the cavity. Actually, however, since the ovule of *Cocos* is anatropous the micropyle lies directly below the hilum or soft eye at the stem end of the nut. As would be expected, the embryo is seated directly below the micropyle. Therefore, the stylar end of the fruit is oriented downwards as the fruit hangs on the palm, and the endosperm meristem is initiated at the antipodal end of the sac. Also, as pointed out above, this meristem forms on the endothelial surface and not on the endocarp, which is separated from the cavity by two thick integuments.

There is also some divergence between our observations⁸ and those of Dutt on the mode of nuclear division in the ripening embryo sac, since we have never been able to detect any mitotic divisions in the free nuclei of the milk, in the endosperm vesicles or in the younger stages of the gelatinous syncytium. In Dutt's opinion, mitosis occurs during all these stages, and she figures a nucleus in mitosis in a drop of milk. Since she claims not to have found any free nuclei in the milk "until a little of the endosperm, if only the barest film, has begun to form", it is probable that the nuclei she pictures were torn from the meristematic endosperm during the opening of the nut. We have frequently noted at this stage that large plates of meristematic cells will detach themselves from the endothelial walls, break up and float free in the milk if the nut is shaken. In the young cellular meristem at this stage mitoses are frequent. On the other hand, in the stages prior to formation of the meristem, we find that constricted or fragmenting nuclei are very abundant in both milk and endosperm vesicles. We have, however, found no evidence of spindle formation in connexion with these constricting nuclei, which leads us to believe that amitosis rather than mitotic division is characteristic of the syncytial stages. In addition, there are always numerous pycnotic nuclei here, which is suggestive of amitosis. While it is possible that the amitotic figures observed actually represent stages of nuclear fusion, this does not seem likely since the

greatest frequency of amitotic figures in the liquid syncytium is encountered at the same stage in development when the maximum number of nuclei appear there.

On all other features of the development of the fertilized embryo sac Dutt's observations and ours are in agreement.

This investigation has been aided by a grant from the American Cancer Society upon recommendation of the Committee on Growth, National Research Council.

Control of Mitotic Activity

THE mechanically active phase of nuclear reproduction is closely associated with the appearance of polymerized deoxyribonucleic acid (DNA) on the chromosomes. Furthermore, it has been shown that cells containing little or no DNA do not divide¹ and that continued synthesis of this form of nucleic acid is essential for further nuclear reproduction². The actual synthesis of DNA appears to take place during interphase^{3,4}, although it is not yet fully established whether it is produced directly from the store of ribose nucleic acid (RNA) or from other sources. But whatever the processes involved, any modification leading to the disappearance or reduction of deoxyribonucleic acid from the cell will act as a mechanism whereby nuclear division may be regulated.

Such a mechanism appears to operate in the embryo sacs of *Vicia faba*, *V. sativa* and *Lens esculenta*, which I have been studying in relation to fertilization and embryo development. The differentiated egg and central fusion nuclei, which are not required to divide until the time of fusion with the male gametic nuclei, contain little or no DNA. With these nuclei, Feulgen gives a completely negative reaction while the methyl green-pyronin technique indicates the presence of ribonucleic acid only.

In the mature pollen grains, on the other hand, the generative nucleus is Feulgen-positive while the vegetative nucleus gives a negative reaction. This is similar to the observations of Painter⁵, Koller⁶ and Le Cour⁷ on the pollen grains of *Tradescantia*. Thus, during the process of differentiation the vegetative nucleus, which does not undergo further division, loses the ability to synthesize DNA. Support for this concept is provided by the case of *Sorghum*⁸, where the presence of supernumerary heterochromatic chromosomes, with a different DNA cycle, brings about the continued division of the vegetative nucleus, resulting in what has been called an 'encapsulated tumour'.

Thus, in contrast to the absence of DNA from the mature egg, central fusion and pollen tube nuclei which do not divide further, we have the generative

nucleus, which contains DNA, invariably dividing to produce two male gametic nuclei, both of which also contain DNA. Here it is interesting to note that Coulter and Chamberlain³ as far back as 1903 were able to differentiate between the female and male nuclei in the embryo sac on the basis of staining reactions without, however, realizing its significance.

From these observations we may further suggest that the division of the fertilized egg and central union nuclei is initiated by the re-introduction of DNA by the male nuclei. A similar explanation would also apply for the normal development of sea urchin eggs, where again only the sperm nucleus appears to contain deoxyribonucleic acid.

This view that DNA synthesis provides a regulating mechanism for nuclear activity has wider implications, of which the following may be mentioned.

(a) The reference by Darlington and Mather⁴ to the apparent development of vetch plants from lentils seed can now be seen in a different light. Only the male vetch nucleus contains the DNA necessary for further development on failure of fertilization, thus supporting the suggestion of androgenesis (male parthenogenesis).

(b) If the egg nucleus in the embryo sac never contains DNA, then it is difficult to understand how an embryo can develop in apomictic forms of reproduction where the male gametic nuclei play no part. There is some evidence, however, that the egg in apomictic forms of *Rubus*⁵ does contain DNA, and this may be associated with the fact that the embryo sac has developed directly from a somatic cell.

Further work is in progress in an attempt to establish more precisely the conditions which determine, on one hand, a discontinuance of nuclear division in the haplophase and, on the other, the resumption of division in the diplophase. It forms part of an investigation being carried out with the aid of a grant from the Agricultural Research Council and under the helpful guidance of Prof. P. T. Thomas.

Chemical Composition of the Cell Wall of *Coccidioides immitis*

THE taxonomic position of *Coccidioides immitis*, the causative agent of coccidioidomycosis, has been debated for some time. It is evident from the method of endospore formation exhibited both in the parasitic phase and under certain cultural conditions^{1,2} that the mature *Coccidioides* cell is a sporangium and the endospores, sporangiospores. This indicates a probable relationship with the Phycomycetes^{3,4} and even possibly with the sub-class, Zygomycetes⁵. However, certain characteristics inconsistent with such a rela-

tionship, including the development of a richly septate mycelium and the absence of definite sporangia, present some taxonomic difficulties. Nevertheless, as noted by Emmons⁶, the sporangia of many of the Zygomycetes (for example, *Mortierella* and *Syncephalis*) present so many anomalies that *Coccidioides* may well find a place within the group. Frey⁷ has shown that the Phycomycetes may be divided into two distinct groups: the one having cellulose (Oomycetes), the other having chitin (Blastocladales and Zygomycetes) as skeletal material of their cell walls. Therefore, we thought it might be of interest to isolate and identify the non-water-soluble polysaccharide forming the skeleton of the cell wall of *C. immitis*.

A mixture of strains 2150 and 2200, both of which had been received originally from Dr. N. F. Conant, of Duke University Medical School, Durham, North Carolina, were grown at room temperature in shake culture in two half-litre Fernbach flasks in 1 litre of a tryptic digest of beef-heart medium containing 2 per cent glucose. The pH of the medium was 7.6. Massive amounts of growth were obtained on this medium in 3-5 days. The cultures were killed on the fifth day by autoclaving at 10-lb. pressure for thirty minutes and the growth was harvested by filtration. The material was washed repeatedly with distilled water on a Buchner funnel to remove the adhering medium and the mycelium was then dried in an oven at 90°-110° C.

The dried mycelium was extracted and oxidized as described by Scholl⁸. Debye-Scherrer diagrams of the isolated substance were very kindly prepared for us by Dr. W. Epprecht, Eidgenössische Materialprüfungs- und Versuchsanstalt, Zürich. These showed the typical powder pattern for chitin; there were no diffraction lines for cellulose. Nitrogen determinations confirmed these findings (N = 5.68, 5.85 per cent).

The isolation of chitin from the mycelium of *C. immitis* is consistent with Frey's findings in the Zygomycetes. It does not allow any definite conclusion as to the taxonomic position of this organism since chitin forms the skeletal material of fungi other than the Phycomycetes. Nevertheless, it does show that all fungi pathogenic for man and animals, whether they parasitize the keratin of hairs, skin or nails or the deeper tissues, have chitin as skeletal material of their cell walls^{9,10}.

A Cyanocobalamin-Protein Complex from Sow's Milk and Desiccated Pig Stomach

We have already reported the partial purification from sow's milk and desiccated pig stomach of proteins which combine with cyanocobalamin and the vitamin B₁₂-like substances having different nucleotide groups¹. Purification of the protein from sow's milk whey was achieved by continuous electrophoresis on paper². Because of the labile nature of the protein itself, we found it easier to saturate the impure concentrate with cyanocobalamin labelled with cobalt-60 and to isolate the cyanocobalamin-protein complex. Purification of this complex by continuous electrophoresis on paper³ was followed by repeated fractionation with isopropyl alcohol at -5°. A recent preliminary note by Wijmenga, Thompson, Stern and O'Connell⁴, concerning a similar cyanocobalamin-protein from pig gastric mucosa, has prompted us to give a brief account of the properties of our substance isolated from sow's milk. Full experimental details will be published elsewhere.

The pink protein complex from sow's milk has the absorption spectrum shown in Fig. 1. The absorption at 278 mμ is largely due to protein ($E(1\%, 1\text{ cm.}) = 15.1$) and at 362 mμ to cyanocobalamin ($E(1\%, 1\text{ cm.}) = 5.7$). The total nitrogen (micro-Kjeldahl) is 16.1 per cent, and 1 mgm. of the complex contains 23.6 μgm. cyanocobalamin. From these figures, and assuming that one molecule of protein combines with one molecule of cyanocobalamin (mol. wt. = 1,300), the molecular weight of the protein would be 55,000. Qualitative examination of the hydrolysed complex shows an amino-acid pattern typical of proteins. Spectroscopic investigations, by the method of Holiday⁵, shows the rather high tyrosine content of 17.6 per cent. The presence of 7 per cent hexosamine suggests a glycoprotein rather than a mucoprotein.

Cyanocobalamin exists in the milk of the sow, woman, rat, goat and cow in bound forms. Gregory, Ford and Kon⁶ showed that sow's milk, but not cow's milk, combined with added cyanocobalamin. However, this procedure involved heating the milks with the assay medium. We have since developed an ultra-filtration method which shows that all these milks when raw and untreated can bind some added cyanocobalamin. Compared with sow's milk, the amount bound by the other milks is small. The electrophoretic mobility of the naturally occurring bound cyanocobalamin in all the milks and of the complexes formed by adding cyanocobalamin to these milks or to desiccated pig stomach was -3.1×10^{-5} cm.² V.⁻¹ sec.⁻¹ at pH 8.6, $\mu = 0.05$.

We have also investigated the mode of linkage between cyanocobalamin and the protein. Removal of the nucleotide and the most labile amide group from the cyanocobalamin molecule⁷ did not prevent its combination, but hydrolysis to the hexa- or hepta-acids⁸ gave a substance which could no longer be combined with the protein. The absorption curve (Fig. 1) with a peak at 362 mμ suggests that the complex contains cyano- rather than hydroxycobalamin. When ¹⁴CN-labelled cyanocobalamin was added to the partially purified binding protein from pig stomach and the whole was dialysed, no radioactivity could be detected in the dialysate. After purification (as described above), the pink protein complex still contained carbon-14 activity, indicating that the protein did not displace the cyanide during combination with the vitamin.

Specific groups on the molecule of the protein isolated from sow's milk were blocked by various reagents, and the capacity of the modified protein to bind cyanocobalamin was measured. Free -SH groups were not necessary for the binding. An -NH₂ or >NH group may be involved since, after reacting with fluorodinitrobenzene, the protein no longer bound cyanocobalamin. However, milder treatments for blocking -NH₂ groups, such as 3 per cent formaldehyde at pH 8 or an acetylation procedure using acetylthioethylacetamide at pH 10, did not interfere with the binding.

For a quantitative microbiological estimation of the cyanocobalamin in the complex, preliminary digestion with pepsin or trypsin is necessary. Enzyme digestion converts the microbiologically inactive cyanocobalamin complex into a form fully active for *Lactobacillus leichmannii* when heated with the assay medium but having only 20 per cent of this activity when assayed unheated. Furthermore, ultra-filtrations of the unheated and heated digests showed that not more than 10 per cent of the total cyanocobalamin had become ultra-filtrable. Since cyanocobalamin itself can be ultra-filtered quantitatively, it appears possible that the digest contains peptide conjugates of cyanocobalamin.

There seems no doubt that the substance isolated by us from sow's milk is very similar to the cyanocobalamin-protein isolated by Wijmenga *et al.* from hog gastric mucosa. The only discrepancy is that we find that 1 mgm. of the complex contains 23.6 μgm. cyanocobalamin, whereas Wijmenga *et al.* find only 12.3 μgm.

We wish to thank Dr. E. Lester Smith (Glaxo Laboratories) for gifts of ⁶⁰Co cyanocobalamin and ¹⁴CN cobalamin and the cyanocobalamin hydrolysis products, and Dr. S. K. Kon for his advice and interest in this work.

Odour and Chemical Constitution

NOTHING is known of the mechanism by which small amounts of odorous material can trigger nervous impulses leading to smell sensations, because the characteristic odour of a substance has not hitherto been securely correlated with any other characteristic property of its molecules.

Some years ago, G. M. Dyson¹ concluded that odour must be related to a characteristic molecular vibration pattern, and he assigned certain odours to certain Raman frequencies ("oemic frequencies") in the general range 1,500–3,000 cm^{-1} . In this region, Raman lines are correlated strongly with particular functional groups (OH, SH, OO, etc.), so that if odour could be correlated with these frequencies it could equally well be correlated with the corresponding functional groups and there would be no need for a vibrational theory of odour. On the other hand, Raman lines below about 1,000 cm^{-1} appear to depend upon the whole configuration of the molecule more than on the constituent groups. Odour also appears to depend more on the whole configuration of the molecule, so that a correlation of odour with vibration would be more reasonable at low frequencies than at high. Moreover, the Planck formula shows that only normal vibrations with a wave number considerably less than 1,000 cm^{-1} have a significant probability of being active at body temperature.

Dyson's 'oemic frequencies' are therefore excluded on both chemical and quantum grounds, and any correlation between odours and molecular vibration patterns must be looked for at frequencies below about 700 cm^{-1} corresponding to absorption in the infra-red beyond about 15 microns. This region does not seem to have been previously searched for odour correlations.

A panel of fifteen observers was used to select sixteen compounds with an odour resembling that of nitrobenzene. Of these compounds, all but one (nitrothiophene) were benzene derivatives, and all but one (isocoumarane) had multiple bonds in the side-chain conjugated with the ring. Apart from this general similarity of type, the compounds had such varied functional groups as nitro, nitrile, aldehyde, ketone, ester, etc. When the low-frequency Raman shifts of these compounds were scrutinized, there was some evidence of a statistically significant correlation between the odour and the pattern of the Raman lines. This work is being reported in detail elsewhere.

The Raman frequencies below 800 cm^{-1} of three of these compounds (nitrobenzene, nitrothiophene and benzonitrile) are shown in Fig. 1. A search of the literature for substances with unrelated structures but similar Raman spectra showed that butyronitrile met the requirements fairly well. In the opinion of six observers, its odour is somewhat almond-like. The successful selection at the first attempt of an aliphatic compound with the same general type of odour as a group of sixteen aromatic substances is

something which no other theory of the physical basis of odour would enable one to do.

A correlation of odour with the pattern of molecular vibrations may therefore be possible if the frequency-range below 1,000 cm^{-1} is studied. The Raman effect is at the present the most convenient tool for the purpose.

R. H. WRIGHT

Division of Chemistry,

¹ Dyson, G. M., *Perf. Essenc. Oil Record*, 18, 456 (1928); 23, 13 (1927); *Chem. and Indust.*, 16, 647 (1938).

In the early 'twenties when the first work on this aspect of oemics was under active consideration our knowledge of the Raman lines below 1,000 cm^{-1} was rudimentary, and while correlation between structural groups and the higher frequencies is now fairly well established, the need for a vibrational theory of odour does not, in my view, automatically disappear.

The interesting results established by Mr. R. H. Wright prove, if they prove anything, that the original hypothesis correlating odour specificity with molecular vibration was sound in principle, but that I was wrong in assuming the frequencies concerned to be those in the higher Raman ranges. He has made a valuable advance in this field by focusing attention on the significance of the lower frequencies; they relate to the molecule as a whole and this, in itself, is an attractive development of the original thesis. There are, however, several groups of compounds which must come under review before the theory can be fully accepted: I refer in particular (a) to the group $R.C_6H_4.NCS$ which, when $R=H$, $o-CH_3$, or $o-Cl$, retains the mustard-like odour associated with allylthiocarbimide, but when $R=CH_3$, $p-Cl$, $p-OCH_3$, acquires a strong odour resembling anisaldehyde (on *passant*, 4-cyanophenylthiocarbimide has a strong almond component to its odour); (b) the 'camphor-like' groups in which such diverse substances as camphor, hexachloroethane, benzene hexachloride and perchloronaphthalene have closely related odours; and (c) the 'tea-rose' thiazoles of Bogert, which have odours reminiscent of phenyl acetaldehyde or the esters of phenylacetic acid.

Effect of Flight on Behaviour of *Aphis fabae* Scop.

AFTER a preliminary period of quiescence newly moulted alate alienicolae of *Aphis fabae* Scop. take flight, in suitable physical conditions, whatever the quality of the host they are on. When they alight on a host plant after a sufficient flight they do not take off again immediately¹ as they do before sufficient flight², and they may settle down and bear young. Moericke³ thought that this indicated two phases in the life of alate aphids, the *Zugphase* and *Befallsphase*, and Müller and Unger⁴ attributed the transition from one to the other to exhaustion. The following experiments show that the change can be brought about by flight itself, and that it is not necessarily permanent.

The experiments were carried out in a greenhouse and the laboratory at temperatures between 20 and

Fig. 1

30° C., on alate from laboratory cultures and natural infestations of broadbeans (*Vicia faba* L.).

The aphids were given flight exercise by attaching them by the thorax to small pins with water-colour paint, and also by permitting untethered flight in the greenhouse. In this way it was shown that a very short flight of an average of about 20 sec. was sufficient to result in the changed behaviour when the aphids were returned to their host plants. The change could be induced by longer periods of activity other than flight, as when the aphids were kept in the light for several hours in a narrow glass tube in which they were able to crawl but unable to fly.

Aphids alighting on a host plant after sufficient flight wander about for several minutes and whether they stay or leave is influenced by the host suitability. Flown aphids placed on highly suitable hosts (6 cm. high broadbean seedlings) settled and remained there until they had lost the ability to fly; on less suitable hosts (isolated mature broadbean leaves) they took off again. Aphids placed on young plants of broadbean 1 metre high showed a considerable variation in behaviour after wandering; a few remained but most of them took off again, this agreeing with the field observations of other workers^{1,4}.

Parturition occurs soon after the aphids settle down on seedlings after flight, or are confined after flight on mature leaves in the dark; its initial rate is influenced by the state of development of the embryos and not by the quality of the host⁴. Nor is it necessary for the aphids to feed for them to stay and bear young, contrary to the assumption of Kennedy and Booth⁴. When unflown aphids are confined on host plants by darkness from flight maturity, embryonic development continues but no larvae are born for two days or more, although several hours after reaching flight maturity the ovaries contain 8-12 fully formed embryos. Such aphids when flown commenced to bear young within an hour of settling, and a number of larvae were then born at half-hourly intervals; an average of 9.0 ± 0.24 larvae were born overnight ($n = 77$). Aphids flown as soon as they reached flight maturity gave birth to an average of only 3.4 ± 0.20 larvae overnight ($n = 50$). Anything, therefore, which delays the initial take-off of the aphids from their parent host plant will help to reduce the length of their flying life by increasing the number of larvae born in the first batch and so hastening the processes leading to the autolysis of the flight muscles¹.

Young aphids which have alighted on an unsuitable host or have been disturbed while feeding on a suitable host may take off again, and a further short flight is necessary before they will settle down to feed and reproduce.

This work will be published in detail elsewhere.

I am indebted to Dr. C. G. Johnson and Dr. J. S. Kennedy for reading this communication in draft.

The Marshes of the Medway Estuary In Romano-British Times

THE view has long been held that the Romano-British pottery and clay fire-bars which occur at various levels in the Scrobicularia Clay (that represents the bulk of the estuarine deposits which compose the marsh) constitute the output and appurtenances of contemporary potters' kilns which had been sited somewhere on the marsh.

The makers' stamps on the pottery cover a period ranging from the middle of the first century A.D. to the third quarter of the second century; though the greater number of the stamps fall within the Hadrian-Antonine phase, namely, between A.D. 117 to A.D. 161.

The present Ordnance Survey maps (scale 6 in. to 1 mile) of the area in question set across many of the saltings the following legend: "Roman Potteries (Site of)". Indeed, that of "Kent" (Sheet XX, N.E. Edition, 1908) shows no less than four such sites.

As the result of twenty-five years study of the deposits of the Uphurh Marsh, I write to suggest that this area could not possibly have supported a Romano-British pottery-making industry. The evidence upon which this suggestion is founded is two-fold—one geological, the other archaeological. There is overwhelming proof that shortly after the commencement of the second century A.D. the sea had obtained complete control over the whole district and that Scrobicularia Clay had been universally deposited to the level of 5 ft. above O.D.

At this stage Romano-British man occupied the intertidal surface of the marsh-clay for the purpose of making salt. This industry is reflected in the occurrence over widespread areas of a specific deposit containing briquetage, clay fire-bars which were required for the process of salt-making, broken pottery and animal bones.

Over this accumulation of refuse—which varies in thickness from 6 in. to 3 ft.—the sea continued its deposition of marsh-clay up to a height of 11 ft. above O.D., which forms the highest level of the present-day salting surface.

A detailed description of the various archaeological horizons which occur in these estuarine deposits will be furnished in a paper to be read later in the year.

Zoological Nomenclature

NOTICE is hereby given that the International Commission on Zoological Nomenclature has under consideration the following case involving the possible use of its plenary powers: *Caenites* Buckman, 1925 (Class Cephalopoda, Order Ammonoidea), proposed suppression of. Full particulars of this case are given in Part 12 of volume 6 of the *Bulletin of Zoological Nomenclature*.

Any comments on the above case should be sent to me as soon as possible and, in any event, should be dispatched in time to reach me not later than August 26, 1954, when voting on this case will begin.

FRANCIS HEMMING

(Secretary to the International Commission
on Zoological Nomenclature)

- 28 Park Village East,
Regent's Park, London, N.W.1.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Sunday, May 2—Friday, May 7

SOCIETY OF DAIRY TECHNOLOGY (at the Northern Counties Hotel, Portrush, Co. Antrim, Northern Ireland)—Summer Meeting.

Monday, May 3

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. T. R. Armstrong: "Northern Sea Route".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION AND FATS AND OILS GROUP (in the Chemical Society's Rooms, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Prof. T. P. Hilditch, F.R.S.: "The Fats: a Story of Nature's Art".

Tuesday, May 4

INSTITUTION OF POST OFFICE ELECTRICAL ENGINEERS, LONDON CENTRAL (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Annual General Meeting; Mr. D. W. Morris, Mr. W. G. Shadlock and Mr. R. W. Thurlow: "Short-Wave Directional Aerial Systems".

UNIVERSITY OF LONDON (in the Metallurgy Theatre, Imperial College of Science and Technology (Royal School of Mines), Prince Consort Road, London, S.W.7), at 5 p.m.—Prof. P. G. Kihlstedt (Stockholm): "The Economical Adaptation of the Beneficiation Processes". (First of four lectures on "Some Important Points in the Utilization of Low-Grade Ores by Mineral Dressing". (Further lectures on May 6, 10 and 11).)

SOCIETY OF CHEMICAL INDUSTRY, CORROSION GROUP (in the Lecture Theatre of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Annual General Meeting, followed by a discussion on "Corrosion and Design".

Wednesday, May 5

ROYAL MICROSCOPICAL SOCIETY (at Tavistock House South, Tavistock Square, London, W.C.1), at 11 a.m.—Symposium on the "Gold Apparatus".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Commander C. G. Mayer: "Colour Television".

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Commandant G. S. Houbt: "13,000 Feet Under the Sea".

UNIVERSITY COLLEGE LONDON (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. R. Partington: "Some Aspects of Seventeenth-Century Chemistry". (Further lectures on May 7 and 10).)

BRITISH INSTITUTION OF RADIO ENGINEERS, LONDON SECTION (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. P. M. Ratcliffe: "Microwave Measuring Equipment".

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Scientific report.

Thursday, May 6

LABORATORY ANIMALS BUREAU (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 10.45 a.m.—Symposium on "The Design of Animal Houses".

PHYSICAL SOCIETY, OPTICAL GROUP (at the Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Dr. R. H. Kay: "A Spectrophotometer for Estimating Ozone in the Atmosphere"; Mr. D. F. Feder: "Optics at the Bureau of Standards".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. J. H. Quastel, F.R.S.: "Soil Metabolism" (The Leeuwenhoek Lecture).

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. Peter Scott: "A Population Study of the Pink-footed Goose" (Illustrated by a film taken in Iceland). Dr. W. J. L. Sladen will give a preliminary report of the flora of the area, illustrated with coloured slides.

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. F. S. Collier: "The Forest Resources of the Colonial Territories and their Management".

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Dr. R. H. Marinko: "The Story of the Iodoquinoline Alkaloids" (Centenary Lecture).

SOCIETY FOR VISITING SCIENTISTS, LTD. (at 5 Old Burlington Street, London, W.1), at 7.45 p.m.—Discussion Meeting: "World Population—Views from Brazil, India and the United States". Chairman: Prof. L. Dudley Stamp, O.B.E. Speakers: Prof. H. O'Reilly Sternberg, Prof. George Kurlyan and Prof. George B. Cressy.

Thursday, May 6—Saturday, May 8

INSTITUTION OF CHEMICAL ENGINEERS, CHEMICAL ENGINEERING GROUP of the SOCIETY OF CHEMICAL INDUSTRY (joint conference with the ROYAL INSTITUTION OF ENGINEERS (Chemical Engineering Group) of the NETHERLANDS and the ROYAL NETHERLANDS CHEMICAL SOCIETY (Section for Chemical Technology, at Koninklijk Instituut voor de Tropen, Mauritskade, 63, Amsterdam))—Conference on "Oxidation Processes".

Friday, May 7

ROYAL INSTITUTION OF CHEMISTRY (joint meeting with the MICRO-CHEMISTRY GROUP of the SOCIETY OF PUBLIC ANALYSTS, in the Zoology Lecture Theatre, The University, Reading), at 7.45 p.m.—Symposium on "Microchemical Methods in Biochemistry".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. W. H. Thorpe, F.R.S.: "The Analysis of Bird Song".

Saturday, May 8

NUTRITION SOCIETY (in the Lecture Theatre, Department of Biochemistry and Physiology, The University, Glasgow), at 11 a.m.—Symposium on "Nutrition and the Liver". Chairman: Prof. J. N. Davidson.

SOCIETY FOR ANALYTICAL CHEMISTRY, WESTERN SECTION (at the Technical College, Newport, Mon.), at noon—Inaugural Meeting. Dr. D. W. Kent-Jones: "Alcohol Determination and its Medical Legal Aspects".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

NUCLEAR POWER ENGINEER (with a degree in physics or electrical engineering, and a knowledge of atomic physics, thermodynamics and metallurgy, and good practical experience), to organize and lead a new branch of the Chief Engineer's Department, which initially will be engaged on design studies of thermal reactors and the conversion of the liberated heat into electricity, and later will be required to design, construct and operate nuclear power stations—The Director of Establishments, British Electricity Authority, Winsley Street, London, W.1, quoting AB/476 (May 5).

ASSISTANT LECTURER (graduate or about to graduate, and with special qualifications in palaeontology and stratigraphy) in GEOLOGY—The Registrar, King's College, Strand, London, W.C.2 (May 8).

LECTURER in the DEPARTMENT of GEOLOGY and MINERALOGY—The Secretary, The University, Aberdeen (May 8).

LECTURERS or ASSISTANT LECTURERS in CIVIL ENGINEERING or SURVEYING, PHYSICS, VETERINARY MEDICINE and PHARMACOLOGY, at the University College of Khartoum, Sudan—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 9).

ASSISTANT LECTURER in PHYSICAL-ORGANIC CHEMISTRY, and a LECTURER in THEORETICAL PHYSICS—The Registrar, Queen Mary College, Mile End Road, London, E.1 (May 10).

LECTURER (with an honours degree in chemistry, and experience in industry, teaching or research) in CHEMISTRY—The Principal, Wigan and District Mining and Technical College, Wigan (May 10).

BIOCHEMIST to work on the proteins of eye tissues with particular reference to pathological conditions—The Secretary, Nuffield Laboratory of Ophthalmology, Walton Street, Oxford (May 14).

CHEMIST/BACTERIOLOGIST (with an honours degree in chemistry or member of the Royal Institute of Chemistry, and preferably with waterworks experience) in the Christchurch laboratory of the West Hampshire Water Company—The Chief Engineer, West Hants Water Company, 21 Stour Road, Christchurch (May 17).

JUNIOR FELLOW in APPLIED MATHEMATICS—The Registrar and Secretary, The University, Bristol (May 17).

SCIENTIST, Grade 3 (with an honours degree in mathematics or statistics) on the London Headquarters Staff of the Director of Scientific Control, for work which mainly consists of the design of experiments and the analysis of experimental data obtained by the Board's scientists in the coalfields—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/771 (May 17).

ASSISTANT LECTURER (with either a special qualification in connection with the mechanical testing of metals or experience in the chemical aspects of metallurgy) in METALLURGY—The Registrar, The University, Manchester 13 (May 22).

LECTURER in AGRICULTURAL BOTANY at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 22).

LECTURER in THEORETICAL PHYSICS—The Registrar, University College of North Staffordshire, Keele, Staffs (May 22).

RESEARCH FELLOW in CHEMISTRY—The Registrar, University College, Singleton Park, Swansea (May 22).

NUFFIELD RESEARCH FELLOW in PHYSICS, a RESEARCH PHYSICIST, and a RESEARCH ASSISTANT, for work in connection with the cyclotron and synchrotron programmes of the Nuffield Research Laboratory—The Registrar, The University, Birmingham (May 20).

LECTURER in EDUCATION at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (May 31).

LECTURER (preferably with qualifications in applied mathematics and/or engineering mathematics) in MATHEMATICS, at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (New Zealand, May 31).

LECTURER (with British university qualifications, or equivalent, and some experience in teaching geology in a University Department of Geology and Geography) in GEOLOGY, at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (May 31).

READER in APPLIED MATHEMATICS at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 31).

ASSISTANT LECTURER (graduate in physics, engineering or chemical engineering, and preferably with experience in the food industry)—The Registrar, National College of Food Technology, Cranwood Street, London, E.C.1.

Advertisers please note. You must add "Apply Employment Exchange" unless the "employment advertised or the workers referred are accepted under the Notification of vacancies Order."

DUNLOP RUBBER COMPANY HAVE vacancies on the tyre technical staff for young men, age 20 to 25, with (a) a degree in physics, mechanical engineering, or (b) Inter.B.Sc., or local certificate in applied physics or mechanical engineering. The positions provide good opportunities for gaining a thorough knowledge of rubber technology and tyre manufacturing methods, and will involve the carrying out of industrial research. There are good prospects of advancement either in the home or overseas situation. Applications will be considered from men who will be graduating this summer. Locations in writing, giving details of age, education, etc., to Personnel Manager, Dunlop Tyre Co., Ltd., Fort Dunlop, Birmingham, 24.

SENIOR METALLURGIST, WITH SOME years' postgraduate experience in light alloys, either in the aircraft industry or in the creation of components, and preferably with a knowledge of casting and forging, is required by English Electric Co., Ltd., Luton, for an existing position in a rapidly expanding industry. Applications to Dept. C.P.S., 336-7 Strand, W.C.2, quoting ref. 1112C.

CHEMISTS WITH GOOD HONOURS Degree required by The British Drug Houses Ltd. Development Research in fine chemicals and pharmaceutical substances. The posts are progressive and provide scope for advancement to managerial status. Commencing salary will be according to qualifications and experience. Fifty week. Pension and Profit Sharing Schemes. Interview and Sports Club.—Apply, stating age, qualifications, experience, and salary required, to the Staff Manager, The British Drug Houses Ltd., Graham Street, City Road, London, N.1.

BRITISH CELANESE LIMITED, MANUFACTURERS of Textiles, Plastics, and Chemicals, have a few vacancies in research, development, production work for well qualified and able chemists, Physicists, Mechanical Engineers, and the Technologists, aged between 25 and 35 years. Applications will be considered from graduates returning from National Service as well from those who are at present in industry. Opportunities for promotion are good for outstanding men who possess initiative, drive and devotion. Starting salary and increments will commensurate with the responsibilities undertaken. 1. Contributory pension fund and all the amenities.—Applicants should send full details of career and qualifications in confidence to Personnel Manager, British Celanese Limited, 43 Hanover Square, London, W.1.

VACANCIES OCCUR IN THE RESEARCH Development Laboratories of British Geon Ltd. for staff to undertake work in the following fields: 1. Polymerization Research.—Men having a good honours degree in chemistry or of Ph.D. standing, with experience in polymerization work allied organic research; 2. Plastics Development and Fabrication.—Men having a good honours degree, with and without experience in development and fabrication of plastic materials; 3. Process Development on the Semi-works.—Men having a good honours degree, and preferably with experience in problems arising from the transfer of synthetic organic chemical processes from laboratory scale to pilot-plant scale.—Apply to Staff Manager, British Geon Ltd., Hayes Road, Sully, Near Penarth, Glam., quoting ref. BG.2.

BRITISH TELECOMMUNICATIONS RESEARCH Ltd., a Company associated with the Automatic Telephone and Electric Co. Ltd. and British Insulated Callender's Cables Ltd., has a vacancy for a senior engineer for work on the development of specialized test equipment for telecommunication systems. There is a superannuation scheme and the Company works a five-day week.—Application should be made to the Director of Research, British Telecommunications Research Ltd., Taplow Court, Taplow, Bucks., giving age and full details of education, qualifications, experience and approximate salary required.

AIR FILTRATION. RESEARCH ENGINEER or Physicist required by leading Air Conditioning Company. Preference given to applicants with experience of air filtration work.—Please reply to D. J. Saxby, Tack Air Conditioning Ltd., Orton House, Longmoore St., London, S.W.1.

PHYSICIST REQUIRED TO JOIN SMALL section engaged in fundamental research on friction. Applicants should be under 28 years of age and must have good honours degree and at least two years' research experience. Mathematics bent an advantage. The selected applicant will be required to pass a medical examination and to join the company's superannuation scheme.—Please write, giving full details of age, experience and qualifications, stating salary required, to Personnel Manager, Ferodo Limited, Chapel-en-le-Frith, Via Stockport.

SENIOR ANALYTICAL CHEMIST, F.R.I.C., with experience in food chemistry, required to take charge of the Association's Analytical and Microbiological Assay Section. Some knowledge of bacteriology would be an advantage. Commencing salary of the order of £1,000 per annum, according to age and experience. F.R.S.U. pension scheme.—Apply, as soon as possible, to the Director of Research, British Baking Industries Research Association, Chorleywood, Herts.

GRANTS & SCHOLARSHIPS

BRADFORD EDUCATION COMMITTEE TECHNICAL COLLEGE, BRADFORD DEPARTMENT OF PHARMACY RESEARCH SCHOLARSHIPS

Research Scholarships of the value of £250 per annum are offered to suitably qualified students of British nationality, who may wish to undertake research in the Department of Pharmacy.

Further particulars and forms of application may be obtained from the Principal, Technical College, Bradford, 7, as soon as possible.

WOOLWICH POLYTECHNIC LONDON, S.E.18 Principal: J. S. Tait, Ph.D., B.Sc., A.R.T.C., M.I.E.E., A.M.I.Mech.E.

Applications are invited from honours graduates and from students entering for their final honours (special) degree examination in June next for Research Studentships in (i) Chemistry and (ii) Physics. The Studentship will normally lead to the Ph.D. degree (internal) of the University of London. Its value is £350 per annum, and is tenable for two to three years.

Particulars and application form from Clerk to Governors.

UNIVERSITY OF NOTTINGHAM POSTGRADUATE STUDENTSHIPS AND SCHOLARSHIPS

A number of awards of values varying up to £300 per annum will be made to candidates wishing to carry out research in any appropriate field of learning in arts, law, social science, education, pure science (including one award for cancer research), agriculture, horticulture, agricultural science, or applied science.

Further information and forms of application may be obtained from the Registrar, to whom the completed forms must be returned not later than July 1, 1954.

UNIVERSITY OF GLASGOW COATS FELLOWSHIP IN CHEMISTRY OR PHYSICS (FOUNDED IN 1948 BY MESSRS J. P. COATS, LIMITED)

Applications are invited for the above Fellowship, which is of the annual value of £300 and is tenable for two years. Candidates should be graduates in science of at least one year's standing of a British university. The successful applicant will be required to undertake research in chemistry or physics (excluding nuclear physics) in the University of Glasgow. Appointment will date from October 1, 1954.

Applications should be lodged with the Clerk of Senate, The University, Glasgow, W.2, not later than May 31, 1954.

UNIVERSITY COLLEGE OF HULL RESEARCH STUDENTSHIP

Applications are invited for a Research Studentship of the value of £300 per annum in the Department of Zoology, dating from October 1, 1954, normally tenable for two years. A Research Student will be expected to undertake a limited amount of demonstratorship.

Particulars may be obtained from the Registrar, to whom applications in triplicate should be sent not later than May 17, 1954.

C. MEGGITT,
Registrar.

UNIVERSITY OF DURHAM KING'S COLLEGE, NEWCASTLE UPON TYNE COCHRANE ENTRANCE SCHOLARSHIP IN METALLURGY

An Entrance Scholarship of the annual value of £95 is available this year to encourage the study of Metallurgy by a candidate of ability coming either direct from school or from employment in the Metallurgical Industry. This award is eligible for supplementation by the Ministry of Education up to the value of a State Scholarship.

Particulars and forms of application may be obtained from the undersigned, to whom applications must be returned not later than June 15, 1954.

G. R. HANSON,
Registrar of King's College.

ROYAL HOLLOWAY COLLEGE (UNIVERSITY OF LONDON)

POSTGRADUATE STUDENTSHIPS, 1954-55
Studentships of £40 eligible for supplementation by the Ministry of Education are offered for the Session 1954-55, with the possibility of renewal for a second year, to men and women who are graduates (in arts or science) of any university. Studentships of £60 eligible for supplementation by the Ministry of Education are offered for the Session 1954-55, with the possibility of renewal for a second year, to women who are graduates (in arts or science) of any university. Particulars may be obtained from the Registrar.

Applications should be forwarded to the Principal, Royal Holloway College, Englefield Green, Surrey, not later than June 8, 1954. The awards will be made in the latter part of July, 1954.

MANCHESTER COLLEGE OF TECHNOLOGY

The British Rayon Research Association offers a Research Scholarship of £300 per annum, plus college fees, tenable for three years, to enable graduates in physics or physical chemistry (first- or top-second-class honours) to work for the degree of Ph.D. of the University of Manchester. The successful candidate will be expected to work in the Department of Textile Chemistry of the College, under the direction of W. W. Barlow, D.Sc., F.Inst.P., on rheological problems connected with the interaction of water with assemblages of hygroscopic fibres.

Applications should be sent to The Registrar, College of Technology, Manchester, 1.

BRITISH OXYGEN COMPANY FELLOWSHIPS

Applications are invited for three postgraduate Fellowships of the annual value of not less than £350 each. Fellowships will be awarded for two years, with the possibility of renewal for a third year, and assistance will be given for equipment connected with the research. In 1954 two Fellowships will be awarded for research on subjects broadly relating to air separation and one for research relating to the use of oxygen in metallurgical operations.

Further particulars and application forms may be obtained from the Secretary, British Oxygen Fellowships Committee, Bridgewater House, Cleveland Row, St. James's, London, S.W.1.

FOR SALE AND WANTED

SCIENCE ABSTRACTS, A and B, 1902-1946. Journal of I.B.E., 1890-1950. Offers 7—Box 916. T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

MISCELLANEOUS

INSTITUTION OF CHEMICAL ENGINEERS

30TH (1954) ASSOCIATE MEMBERSHIP EXAMINATION

Application forms (returnable June 1, 1954) and particulars of the 30th Associate Membership Examination may be obtained from the Secretary, Institution of Chemical Engineers, 56 Victoria Street, London, S.W.1.

ANY COUNTRY'S PERIODICALS supplied regularly. Business, scientific, technical and general publications. You pay in sterling for all publications including U.S. and Canadian. FLUORITE OBJECTIVES

- × 50 (1/7 in.) Oil Immersion N.A. 0.95
 × 100 (1/12 in.) Oil Immersion N.A. 1.30

These new computations of outstanding merit are designed to be used with the NON-DRYING OIL supplied by us.

Compensating eyepieces × 6 and × 8 are available and should be employed to exploit fully the capabilities of these fine lenses.

Each objective is tested on the BAKER OBJECTIVE-TESTING INTERFEROMETER and only the finest selected material is used in manufacture.

BECK MICROMETER MICROSCOPE

Accuracy in measurement

Full particulars of:

R & J BECK LTD • 69/71 MORTIMER STREET
 LONDON, W.1

Catalogue Number NT. 11025.

BRIEF SPECIFICATION

Frequency Range.	20 c/s to 20 kc/s in three ranges.
Calibration Accuracy.	± 0.5 c/s up to 50 c/s. ± 1 per cent above 50 c/s.
Distortion.	Not greater than 2% of maximum output.
Hum Level.	Not greater than 0.2% of maximum output.
Output.	20 volts into external load of 600 ohms, balanced or unbalanced.
Mains Supply.	200-250 volts, 40-60 c/s.

AUDIO-FREQUENCY OSCILLATOR

This instrument employs a resistance-capacitance oscillator circuit, in which the frequency-determining elements have been carefully chosen to ensure stability of calibration. The oscillator section incorporates a control circuit which maintains the output substantially constant at all frequencies. This section is followed by an amplifier and power stage providing an output of 20 volts into an external load of 600 ohms. A surge-limiting circuit is incorporated to prevent sudden mains changes from affecting the output of the oscillator. *Please write for descriptive leaflet.*

ATURE

*"To the solid ground
Of nature trusts the Mind that builds for aye."—Wordsworth*

VOL 173, No. 4410

SATURDAY, MAY 8, 1954

TWO SHILLINGS

THE *Newton*

LONG WORKING DISTANCE ATTACHMENT

... provides a working distance of 12.8 mm. between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm. objective

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

Tinsley

STANDARD CADMIUM CELLS

Single and double types in wooden cases or in metal cases as illustrated.

Reliable single or double miniature types mounted in plastic cases, E.M.F. 1.01859 abs. volts at 20° C. Temp. coeff. —40 μ V/1° C. Low internal resistance. Dimensions 3½ in. × 1½ in. × 1½ in.

Non-temperature coefficient cells for industrial use.

All types of unmounted standard cells can be supplied in quantity from stock.

SECRECY AND SECURITY IN ATOMIC RESEARCH

THE recent debates in Parliament on the Defence Estimates, and the "Statement on Defence, 1954"* on which they centred, were marked by a candour which has often been absent from such debates and by a keen appreciation of the need for informed public discussion of the broad issues, though it was impossible, for security reasons, to discuss details or the magnitude of the effort in particular directions which is being undertaken in Great Britain. In that of atomic energy, for example, Dr. J. B. Conant has expressed the opinion that no full public discussion is possible within the foreseeable future. The subsequent hydrogen bomb developments may well, however, enforce somewhat fuller public discussion, at least on such issues as the apportionment of resources between research and production in different fields of defence and between defence research and civilian research. Moreover, quite apart from the implications of President Eisenhower's proposals of last December for an international atomic pool under the United Nations, and his subsequent message to Congress on February 17 asking for changes in the Atomic Energy Act of 1946 to facilitate wider co-operation with the allies of the United States in the interchange of information concerning the use of atomic weapons, the processing of atomic raw materials, reactor development, production of fissionable materials and related research and development, strong support for more freedom in the exchange of information has been forthcoming from responsible quarters inside as well as outside the United States.

In an article in *Foreign Affairs* last summer, Dr. J. R. Oppenheimer, formerly director of the Los Alamos Laboratory, discussing atomic weapons and American policy, urged more candour in making available to the public the information necessary for informed discussion of the factors which limited the country's choice of action. That is as essential in other countries as in the United States if governments are to be assured of the firm support of intelligent public opinion in the difficult decisions they are called upon to take. This argument is well illustrated in the introduction to the Statement on Defence, 1954. Dr. Oppenheimer equally stressed the need for more candour on the part of the United States in dealing with its major allies. Here he referred both to technical collaboration and to the military collaboration, for which both General Bradley and General Collins had pressed as a precondition of effective planning and successful defence of Europe. Dr. Oppenheimer also argued that more candour is an essential factor in securing public co-operation in the measures of civil defence required to moderate the dangers from atomic weapons or other means of enemy attack on the civil population, and the soundness of his arguments is well indicated in the reactions of some local authorities as well as of individuals in Great Britain

* Statement on Defence, 1954. Pp. 23. (Cmd 9075.) (London: H.M. Stationery Office, 1954.) 1s.

to the statements in the press regarding the hydrogen bomb explosions of March 1 and later.

Mr. Gordon Dean, former chairman of the United States Atomic Energy Commission, in his subsequent book, "Report on the Atom", takes a similar view. Mr. Dean believes that, in the absence of informed public discussion, the United States decision to build up a stockpile of atomic bombs, which became the most important single factor in planning its strategic defence, resulted in the stockpile being carefully concealed so that nothing could be done with it except under the most extreme conditions and with much soul-searching at home and a loss in reputation for morality abroad. This situation gave the U.S.S.R. much more freedom of action in the post-war world than they would otherwise have had, and although Mr. Dean is a convinced believer in the deterrent value of the atomic stockpile, he gives no high place to secrecy in his proposals for improving the security of the United States and the free world. Progress in science, he recognises, has no international boundaries or special environments, and leadership in the atomic field will be maintained by achievement, not by a cloak of secrecy.

This welcome reminder that security and secrecy are not synonymous—and may even be inconsistent—comes, not from a scientist but from a lawyer-administrator, who sees as the goal over the next few years a wide base of co-operation between the scientists and engineers of the United States and Great Britain in the field of atomic energy, conducted in such a way that the Soviet programme is not advanced. There is thus already much support for President Eisenhower's proposals from responsible opinion, both civil and military, in the United States, and it is desirable that discussions of defence policy and of the functions of the Atomic Energy Corporation Bill should be so conducted as to put no fresh obstacles in the way of Anglo-American co-operation and the interchange of information. For the same reason, scientists should do what they can to put discussion of hydrogen bomb developments on a factual basis. Calm judgment and clear thinking, not partisanship or passion, are the way to security.

In his article referred to earlier, Dr. Oppenheimer agrees with Dr. Conant that to-day public opinion does not exist in the field of atomic energy; he pleads particularly that knowledge of the characteristics and probable effects of atomic weapons, of—in rough terms—the numbers available, and the changes that are likely to occur within the next few years, and our general estimate of where a potential enemy stands, are not among the things to be kept secret.

The Civil Estimates for 1954–55 disclose for the first time the magnitude of the national expenditure in Britain on the development of atomic energy, though that on atomic weapons is still concealed within the Service estimates and those for the Ministry of Supply. Nevertheless, the Statement on Defence is a first tentative step towards a public discussion in general terms and itself points to some of the essential questions to be asked, while others emerged in the debates in the House of Commons.

First, the Statement emphasizes the heavy burden on the economy of Britain imposed, not merely by the magnitude of the Defence Estimates themselves but also by the continuing need to devote to defence production a substantial part of the output of the engineering industry. It is thus still necessary to hold a careful balance between the demands of defence and those of other sectors of the economy and, in particular, to ensure by close co-operation with our partners that our share of the common burden does not impose an undue strain on our balance of payments: "Our armed forces cannot, in these circumstances, be provided with all those things which ideally they should have".

That being so, there are two fundamental questions to ask. The first concerns the effectiveness of co-laboration with our partners. There should be no possibility of the cost of security being confused with the cost of independence. Cool, impartial public discussion, when well informed, is a real safeguard against the duplication of research and prototypes, and a powerful stimulus to politicians to create the political conditions which further cheaper and more efficient defence.

The second question relates to the balance of the national effort in Britain, both that between defence and civilian research and development, and that between conventional and new and unconventional weapons. It is here that the biggest problems are now emerging, as the Statement on Defence indicates; and while public discussion could help at least in ensuring support for the difficult decisions which must be taken, it can only help if such discussion is serious and responsible as well as informed. The defence policy outlined is based on the prevention of war and accepts the necessity of keeping our present lead in technical development to offset weakness in man-power. Only by implication is it recognized that Great Britain's foreign policy should be in keeping with the resources available to support that policy, and one of the most striking features of the references to man-power is the absence of any reference to the point made by Sir Godfrey Ince in his paper to the Manchester Statistical Society last year regarding the use of man-power: both in industry and in the Services it is essential that the most fit and active should not be employed on tasks or duties which could be done as well by older and less active men. The point was indeed taken up by speakers in the debates in Parliament, but in respect of the employment of women in the Services.

There may, of course, be room for argument as to the respective roles of the three Services in the overlapping and conflicting tasks arising out of the policy set forth in the White Paper. As to the situation created by the atomic weapons which are already being delivered to the Forces, and by the guided missiles, which have reached an advanced stage of development, the major clash of opinion arose as to the change which should be made in the direction and balance of the research effort of Britain. Moreover, the White Paper itself points out that the balance between new and conventional weapons can only be decided over a period of years in the light of

the situation as it develops, and of the studies in the problems of tactics and training created by the new weapons which are proceeding both in the United Kingdom and under the North Atlantic Treaty Organization. The hope is expressed that these studies will gain in realism and effectiveness as a result of President Eisenhower's request to Congress for legislation permitting the release of more information on the use and effects of nuclear weapons.

Summing up, it is clear that the central theme is the need for the freest exchange of information consistent with national security. At different levels, different criteria will obviously have to be applied. So far as the general public is concerned, sufficient general knowledge relating to atomic energy and to atomic weapons should be made available to enable people to appreciate not only the magnitude but also the limitations of recent developments; by these means alone can a reasoned and balanced view of affairs be achieved. At more specialized and technical levels, the amount of information which can be exchanged must be assessed on a different basis; but secrecy for its own sake has always been a friend of wastefulness, inefficiency and duplication such as can ill be afforded at the present time.

THE NANYANG UNIVERSITY, SINGAPORE

THE proposed Chinese University in Singapore (called "Nanyang" after the Chinese name for South-East Asia) stems immediately from the separate system of Chinese schools in Malaya, but more basically from a deep urge in the Malayan Chinese to preserve their cultural independence. Throughout the country there exist, side by side, English schools (primary and secondary) and Malay, Chinese and Tamil vernacular schools. The latter have far more pupils, but only the Chinese schools constitute a system paralleling the English schools right up to secondary level, and also largely independent of Government help and control. Their main medium of instruction is Chinese, and the English which all their senior pupils learn is not usually enough to qualify them to enter the country's established University, the University of Malaya, where English is the medium of instruction and academic standards are those of the universities of the United Kingdom. Most of its students are indeed Chinese; but they nearly all come from English secondary schools.

Boys and girls from Chinese schools seeking a university education have hitherto commonly gone to China. To-day that has obvious difficulties and disadvantages. Education in China is education in Communism. Those who go there find it hard to return and may be lost to their families and to Malaya. More and more are thus left with no clear avenue to any university. Actual numbers are small; Chinese school pupils are said to total 400,000 against 211,000 in English schools; but whereas there

were 4,339 in English School Certificate classes last year, the corresponding Chinese school classes had only 418, of whom but a fraction will actually seek a university education.

However, the problem, if far smaller than sometimes suggested, is real, and it was primarily to solve it that a group of wealthy Chinese proposed last year to create a new Chinese university in Singapore. They spoke also of providing a centre for the study of Chinese culture and of supplementing the work of the University of Malaya by teaching subjects not yet offered there; and, in answer to a charge of communalism, they proposed to cater for Malayan residents of other races, too.

An initial fund has now been raised, a site decided upon, building plans prepared and—a most important step—a chancellor and a vice-chancellor selected, in the persons of Dr. Lin Yu Tang and Dr. Robert Lim. With one initial promise of 5,000,000 dollars and smaller donations and promises, funds available may be upwards of 7,000,000 dollars local currency (say £800,000). That is no more than a start towards the cost of a modern university; for comparison, the University of Malaya already costs about £650,000 per annum, and the cost of rebuilding it on a new site was put at £17,000,000.

The chancellor is to be the active chief executive, and many decisions may be postponed until Dr. Lin arrives (probably in September) and familiarizes himself with an atmosphere hitherto strange to him. Meanwhile, no academic appointments have been announced; legal authority to issue degrees has still to be obtained; the steps to be taken to guarantee their standard have still to be defined; and no formal announcement has been made of the basis of admission of students. None the less, teaching is planned to start early in 1955, using temporary or borrowed buildings. Initially there are to be Faculties of Arts and Science only and, rather surprisingly, teaching is to be largely in English. The first is a wise decision; it would have been over-bold to tackle fields such as engineering, which the University of Malaya has found too difficult hitherto but will in any event be entering soon.

Certain questions inevitably arise. First, could not a ladder to university education be more easily provided by bringing the Chinese school pupils up to the standards in English language of the University of Malaya, or by giving some teaching in the University in Chinese? The problem is not solely one of language, for there are other marked differences existing in the basic educations given in the English and the Chinese schools; but possibilities of adaptation or extension of teaching in their senior classes or of otherwise bridging the gap between them and the University of Malaya are under active examination. However, the sponsors of the Nanyang University decided that only a quite separate institution could serve their purposes.

Secondly, is the new institution needed for the study of Chinese culture and literature? Long delays had raised doubts whether the University of Malaya would ever give reality to the Department of Chinese Language it had long possessed on paper; but the

appointment last summer of a head of that Department and the purchase of some 80,000 volumes as the basis of a Chinese library have made clear that it does not intend to neglect that field.

Thirdly, what will be the value to the practical-minded student of a Nanyang University degree? Much will depend on the recognition given locally, for example, for Government appointments, and on whether good English continues to be essential in the professions and the other higher appointments to which the local graduate aspires. If the new University offers no reliable avenue to local employment, will it prove an effective counter-attraction to a university education in China, offering a definite avenue to employment there? The answer may depend on whether the Chinese school pupil really wants an education for China or an education for Malaya.

Fourthly, can any university in Malaya to-day establish and maintain itself without constant re-inspiration and reinforcement from outside, as the University of Malaya is inspired and reinforced by its close contacts with the Commonwealth universities? If not, where is the Nanyang University to find such reinforcement outside China?

Hitherto the Chinese in Malaya has had to choose, for his higher education, between a Western system in Malaya or a Chinese system in China. The Nanyang University seeks to offer the alternative of a system geographically in Malaya but culturally inspired by Chinese thinking. It is yet another mark of the great and vital interest taken in education by people of Chinese race, and an interesting experiment in a mixed society of confused cultural loyalties and linguistic habits; but it fits very uneasily with the political aspirations of Malaya to a united and integrated nationhood.

FOUNDATIONS OF MODERN PHYSICS

A History of the Theories of Aether and Electricity The Modern Theories 1900-1926. By Sir Edmund Whittaker, F.R.S. Pp. xi+319. (London: Thomas Nelson and Sons, Ltd., 1953.) 32s. 6d. net.

IF a younger physicist is to review a new book on the history of physics, and if the author of the book has grown up with all the events about which he is writing, then the reviewer is in a difficult situation. Unlike the author, he has not grown up with the material, but has only absorbed the latest stage of the physical theories during his student days and subsequent work, so that he is not familiar with many details in the historical development of even the past fifty years. To review such a book and comment on the historical correctness and completeness of the work, he must study the history of science, and only then is he in a position to make some criticisms. But in regard to this book by Sir Edmund Whittaker, a reviewer must do much more: it warrants a thorough study of physical literature since 1900 before one has the right to make such a statement as: "I do not agree with this or that" or to put one's finger on a mistake.

If one asks why has such a book been written, the answer could be: to spare other people the necessity of reading the enormous amount of scientific papers of the period in question in order to understand the historical evolution; and it is in the attainment of this objective that I feel competent to comment. Before doing this, however, let me return for a moment to the question of historical accuracy. Extrapolation is a well-known scientific technique, and I think it is possible by means of extrapolation to judge even on this question. One need read only a few pages of the book to sense the thoroughness and conscientiousness of the whole work. Furthermore, one will note that no statement is made without being justified by at least one quotation, the total of which I estimate to be more than a thousand. Thus, from this great number of quoted papers, from the personal experience of the author and from the general solidity of the work one may conclude that it is historically complete, for it is inconceivable that an author with such a profound knowledge of his sources could have overlooked any important fact. Indeed, one can rather be sure of the historical objectivity from the thoroughness and the style of this work.

If it be doubted that a younger physicist can make valid criticisms by means of the method of extrapolation, there are indeed three other features of such a work on which he can comment: the extent to which the book fulfils its purpose; the effort it demands from its reader; and one's reactions on reading the work.

Taking the first of these points, the number of facts considered in the 307 pages of text is astonishing. They are not superficially described, but form a carefully ordered and profound analysis of the development of theories. Many of the papers quoted are forgotten to-day; but the ideas do nevertheless form a part of present-day science, and it is impossible to understand the evolution of science without them. But Sir Edmund does not confine himself to enumerating the facts or describing them in simple words. He brings the reader to real understanding by a coherent mathematical description enabling him to follow the development step by step—though, indeed, only if the reader is willing to make a co-operative effort. Besides this, the book can also be used for reference purposes and as a collection of sources. Therefore it is essential for any library.

Turning now to the second point, the book is not written for the layman interested in the history of science, and certainly does not belong to the category of popular science books. The reader should possess a knowledge of differential and integral calculus, tensor calculus, matrices as required for Maxwell's theory of electricity, relativity and quantum theory. But it will suffice if one's knowledge of these topics is somewhat sketchy, because the author gives some assistance, as, for example, by a short introduction on tensor analysis and matrices. The contents of the book can be indicated by the following list of chapter headings: the age of Rutherford; the relativity theory of Poincaré and Lorentz; the beginning of quantum theory; spectroscopy in the older quantum theory; gravitation; radiation and atoms in the older quantum theory; magnetism and electromagnetism; the discovery of matrix mechanics; the discovery of wave mechanics.

How does the reader feel about this book—or rather, how did I feel? The clarity and the excellent didactic construction make it a pleasure to follow

Sir Edmund through the years 1900-26, though his book is sometimes not easy to read because of the condensed style and the fact that he often employs the nomenclature used in original work instead of that which would be used to-day. But this is surely an advantage and not a fault.

Besides the history of physics, one may learn from Sir Edmund one very important fact, namely, that it was of no advantage to have been living fifty years ago in order to make some of the great discoveries which to-day seem to be so easy and self-evident. From this book one can see that things were then much more complicated than they may now seem; in fact, they were just as difficult for physicists of that time as present problems are for us.

R. HAGEDORN

EVOLUTION OF THE HUMAN MIND

Anthropogenesis

A Study of the Origin of Man. By Prof. Ant. Pannekoek. Pp. 120. (Amsterdam: North-Holland Publishing Company, 1953.) 12s.

A THOROUGHGOING analysis of human origins would encompass the physical, the social and the psychological distinctions of *Homo sapiens*. It would indicate the phyletic stage and ecological setting in which hominid features first appear and attain their full expression. For much of what is essentially hominid begins to be recognizable all the way back in the Primate progression, and the transition from prehominid is never likely to be a sharp one. There are characters, too, which are closely interdependent, and a case could be made for their developmental, and perhaps genetic, correlation. Weidenreich, for example, has directed attention to the interacting changes characteristic of the transformation of the face and brain-case and the bending of the basiscranial axis. Already, palaeontology and comparative primatology, guided by the broad principles of animal evolution, offer enough to make the biological exploration of anthropogenesis a fascinating, if complicated, intellectual exercise.

Prof. A. Pannekoek's exploration scarcely touches on the biology of the matter. It is a long, sustained disputation of a hypothesis to account for the genesis of conceptual thinking, language and tool-making. The thesis is skilfully and forcefully argued and is worth following if the reader will bide his time in the opening discursive chapters and be prepared to go in and out of several neurological blind alleys. The theory is an amalgamation and re-ordering of a number of interrelated propositions which have been argued before. These are, briefly, that tool-making implies a developed capacity for conceptual thought (an idea elaborated by Elliot Smith), that speech and conceptual thinking develop reciprocally (as Darwin, ignored by the author, postulated) and, to complete the logical triad, that word-making is closely "akin to tool-making" (Charles Bell). Prof. Pannekoek examines and dissects each of these postulates in detail and finds them intrinsically convincing, though there is scarcely a material check which can be brought to bear on his premises or inferences. He urges the primacy of tool-making as the driving force in the development of the faculties

of human thinking and speech, though he emphasizes that, once started, all three activities would undergo a continuous mutual development. A point he labours is that "simple Darwinism" has led biologists to ignore the cultural factor of tool-making as the most potent agent of cerebral and mental development. But he himself quotes many writers who have accepted this possibility, though perhaps not to the extent of the author himself. There are places where the argument is not clearly developed. The enlargement of the brain is regarded in the main as a resultant of tool-making (p. 78), but some degree of enlargement is apparently a precondition in the earliest stages for cultural development (p. 107). Pannekoek criticizes, and with some justice, Elliot Smith's essentially orthogenetic view of brain expansion.

On Pannekoek's thesis, a protracted period of tool-using and of slow improvement in tool-making with concomitant lagging in brain development must have taken place (the palaeontological record supports this) with word use emerging relatively late. Interestingly enough, Prof. R. J. Pumphrey has recently¹ made a similar inference using less speculative arguments derived from the physical and physiological nature of language. Unlike Prof. Pannekoek, Prof. Pumphrey puts forward a piece of collateral evidence. He infers that the ability to use the "degenerate symbols" of language became increasingly manifest during the Upper Pleistocene; he suggests that this is mirrored in a pronounced tendency for the representational art of that period to exhibit progressive abbreviation and abstraction. The biggest omission in Prof. Pannekoek's discussion is the scant attention given to the emergence of the human social grouping in the development of the faculties of speech and thought.

METHODS OF ORGANIC CHEMISTRY

Methoden der organischen Chemie

(Houben-Weyl.) Vierte, völlig neu gestaltete Auflage. Herausgegeben von Eugen Müller, unter besonderer Mitwirkung von O. Bayer, H. Meerwein und K. Ziegler. Band 8: Sauerstoffverbindungen 3, Peroxyde, Kohlensäurederivate, Nitrile und Isocyanide, Carbonsäuren, Decarboxylierung, Carbonsäureester, Funktionelle N-Derivate der Carboxylgruppe. Pp. xviii+776; 1952; 98 D. marks. Band 2: Analytische Methoden; pp. xxiii+1070; 1953; 139 D. marks. (Stuttgart: Georg Thieme Verlag.)

THE appearance of the first two volumes of a completely new edition of "Houben-Weyl" is a notable event in organic chemical circles. The third edition, of which Vol. 1 was issued in 1925 and Vol. 4 in 1941, enjoyed great popularity which is far from dissipated even now. In the fourth edition the subject-matter has been completely rearranged, and the articles in the two volumes now under review have been enlarged and modernized out of all recognition. The names of the contributors (for example, R. Criegee, H. Henecke, F. Arndt, B. Eistert, H. Roth, Th. Wieland) as well as of the editor and his associates are sufficient guarantee of the authenticity and quality of the work. Serial publications such as

"Organic Syntheses" and "Organic Reactions" and the series of Thailheimer, which have proved invaluable to the synthetic organic chemist, have in no way lessened the importance of "Houben-Weyl", which indeed gives extensive references to articles in the first two of these publications. A large proportion of all the references relates to original papers published after the third edition, and they include reference to many patent specifications and to FIAT reports and reviews.

Vol. 8, published in 1952, was the first volume of the new edition to be issued. It is said that the complete edition will consist of about fifteen volumes. Criegee contributes an article on peroxides, which gives an interesting survey of the several different types of preparative methods now available and contains a short section on the reactions and uses of peroxides. Derivatives of carbonic acid are dealt with by S. Petersen and H.-F. Piepenbrink in two comprehensive sections in which, for example, the reactions of cyanic acid, cyanogen halides, cyanamide, urea and guanidine are summarized in convenient tabular form. Various classes of dimeric and trimeric carbonic acid derivatives are described, and the part dealing with biguanide refers extensively to the publications of F. H. Curd and F. L. Rose and their collaborators in the researches leading to new antimalarial drugs. A long section on nitriles (by P. Kurtz) includes preparative details for anhydrous hydrocyanic acid, cyanogen and acrylonitrile, and contains also a few pages devoted to isocyanides.

The next section is concerned with the preparation, transformations and decarboxylation of carboxylic acids. This covers a whole range of interesting organic reactions. There are descriptions of methods for the direct introduction of the carboxyl group using carbon monoxide or carbon dioxide, of oxidation routes to carboxylic acids, of synthetic methods such as the acetosuccinic ester and malonic ester syntheses, the Perkin and Knoevenagel reactions, and of rearrangements such as the benzilic acid change, the Arndt-Eistert reaction and the Favorsky reaction. Decarboxylation comprises not only direct elimination but also rearrangements such as the Curtius and Schmidt degradations. Equally interesting and useful is the section on carboxylic esters, which gives examples of well-known condensation reactions. These include the Reformatsky reaction, the Darzens glycidic ester synthesis, Claisen's ester condensation, the Stobbe synthesis and the Michael reaction. These examples illustrate, incidentally, the use of the majority of the extensively used condensing agents; but the usefulness of the article would have been enhanced by including a discussion of their relative merits with an indication of the reagent of choice for specific types of reaction and molecular environment. The last section, dealing with nitrogenous derivatives of carboxylic acids, is followed by an author index containing all the names in the footnote references throughout the volume, and a subject index which is largely a list of names of compounds; page numbers of preparative methods are given in heavy type.

Vol. 2, issued in 1953, contains a most valuable comprehensive survey of the methods of analysis and the determination of physical constants of organic compounds. There is a detailed description of qualitative elementary analysis, and the quantitative section rightly gives most prominence to micro- and hemimicro-methods. The determination of oxygen is included among the methods of

elementary analysis, and also the estimation of silicon in organic silicon compounds and of metals in organo-metallic compounds. The 248-page section on elementary analysis concludes, appropriately enough, with a glimpse of the future in the shape of a brief survey of methods of 'ultramicroanalysis' by which, for example, combined carbon, hydrogen and oxygen estimations can be carried out with quantities of the order of 100-300 μgm .

Other analytical methods relate to the determination of specific molecular groups, to gas analysis (including adsorption methods and spectroscopic methods), thermal analysis of molecular compounds, chromatographic analysis and analysis of solvent mixtures. The chromatography section gives a detailed illustrated description of experimental methods, including paper chromatography and the use of ionic resins. In connexion with paper chromatography, it is curious that although the name of A. J. P. Martin appears in the literature references, no mention is made of R. L. M. Synge. Errors in transcription of names are easily made; one of the references in Vol. 2 gives A. C. Cook instead of A. H. Cook, and in Vol. 8 G. M. Bennett appears as G. M. D. Bennet. The section on gas analysis has a table of physical constants of upwards of forty gases, and this section is followed by a section on the determination of melting and freezing points, and of boiling and condensation temperatures. A valuable feature of this volume is the inclusion of a general bibliography at the end of most of the articles.

It is unnecessary to commend these two excellently produced volumes to organic chemists. They will be attracted to them instinctively.

J. W. COOK

MAGNETIC CHARACTERISTICS OF ROCKS

Rock-Magnetism

By Prof. Takeshi Nagata. Pp. viii+232. (Tokyo: Maruzen and Co., Ltd., 1953.) 5 dollars.

THE present interest in the interpretation of the natural residual magnetism of both igneous and sedimentary rocks makes this survey by Prof. T. Nagata of the characteristic magnetic properties of rocks most opportune. Of necessity, any interpretation of the observed natural magnetic polarization must be based upon a full appreciation of the magnetic behaviour of the rock constituents. The main geophysical problem is the cause of abnormal directions of magnetization, differing widely from that of the present earth's field, in many cases being in opposition to it. Two hypotheses have been advanced to account for this phenomenon: one requires large changes in the direction of the earth's field in the past, and the other seeks to explain the reversed polarization in terms of the intrinsic properties of the ferromagnetic constituents and their possible interaction under suitable physical conditions in a normal earth's field.

The opening chapter of the book is of a general nature and gives a brief review of modern ideas on magnetism, with special reference to ferromagnetic materials and the theories, advanced by Néel, of the behaviour of small ferromagnetic particles. It concludes with a review of the more common magnetic

minerals occurring in rocks. The next chapter is on the measurement of rock magnetism which, because of the small intensities of magnetization, requires special techniques. The usual magnetic properties—that is, hysteresis and the associated values of saturation intensity, coercivity and remanence, the effective susceptibility in weak fields, the variation of properties with temperature, Curie temperature, etc.—have one chapter devoted to them. In particular, the rock, regarded as an assemblage of mineral grains, and the relation between properties and concentration of minerals, are treated in some detail.

By far the most valuable, and longest, chapter is that devoted to the thermoremanent magnetism of igneous rocks, for it is this aspect which is of greatest significance in the interpretation of natural residual intensities. The author has made his most important contributions in this branch of the subject, and our knowledge of the details of the manner in which a rock acquires its large and stable intensity when cooled from above its Curie temperature is largely due to his work. The amazing behaviour of the dacite from Mt. Haruna which, when cooled in a weak field, acquires a polarization directed in opposition to the ambient field, is also discussed. Of the last two chapters, one is concerned with the magnetization of sedimentary rocks while the other considers some of the geophysical problems which arise from the general subject.

As a compilation of experimental data of the properties of rocks, mainly under laboratory conditions, this book is valuable; but the interpretation of the results is not always satisfactory or carried out in a sufficiently critical manner. As an example of this, a relation is deduced between the effective susceptibility of rocks in weak fields and their magnetite content. The observations show such a wide scatter that the value of the numerical interpretation is open to question and a significance test is essential for its full appraisal. Again, many of the conclusions are not generally accepted by other workers, particularly that on the mechanism by which the Mt. Haruna dacite acquires its adverse polarization. The book is well printed and generously illustrated. One major fault—for which Prof. Nagata is not responsible—is the English, which leaves much to be desired.

J. M. BRUCKSHAW

WEATHER NEAR THE GROUND

Micrometeorology

A Study of Physical Processes in the Lowest Layers of the Earth's Atmosphere. By Prof. O. G. Sutton. Pp. xii+333. (London: McGraw-Hill Publishing Co., Ltd., 1953.) 61s.

DR. SUTTON has written the book that only he could write; and there will be a warm welcome for this illuminating survey of territory that he himself has done so much to extend. A flipper reviewer will perhaps be forgiven for suggesting that the sub-title ought to be "Mathematical Processes in the Lower Atmosphere", for this is a mathematician's book with the scope and content of which there could be little quarrel were the design limited to producing a survey of postgraduate standard for mathematicians and physicists. The author, however, specifically states that he has attempted to meet the needs of workers in other fields who require detailed information about physical processes in the regions

of the atmosphere where life is most abundant. To these other workers—biologists and the like who make up the great bulk of practising micro-meteorologists in the world—the book will be difficult where it is relevant, and disappointing where it is silent on what they regard as the important problems of micro-meteorology: air movement, temperature and humidity gradients inside crops and forests; the physical environment of insects and animals; the dispersal of atmospheric plankton with non-negligible terminal velocities of fall; and wind erosion, to name only a few. At present, of course, the meteorologist can do no more than provide a qualitative discussion of the physics of some of these problems; but a lead from Dr. Sutton would have been invaluable in stimulating thought and experiment.

The first of the eight chapters clears the way for later arguments in describing the static properties of the atmosphere. The next two deal with air moving in laminar flow and turbulent flow, the former primarily to set out and explain the basic aerodynamic equations and to introduce the concepts of shearing stress, viscosity and mean free path. Against this background there is an extended survey of mixing length theories in turbulent flow, first on the molecular analogy of Prandtl and then on the statistical basis initiated by Taylor. The analysis at this stage is mainly used to derive velocity profiles over smooth and rough surfaces, and the corresponding momentum transport constants. Here, as elsewhere, the mathematics is crisply set out and the argument uninterrupted: but at the expense of a discontinuity it would be helpful to have some discussion of the physical implications of these differing concepts of mixing length.

After considering the transport of heat in free convection, diffusive processes are studied in general terms that permit the analysis to be applied not only to heat transfer but also to imponderables in the atmosphere—water vapour, smoke and other pollution with negligible terminal velocities of fall.

The chapter on radiation is pure meteorology and includes an extended treatment of long-wave radiation leading to a discussion of the possibilities of predicting night minimum temperatures. As 'micro' meteorology this chapter might well have included some discussion of radiation exchanges between small bodies and their environments, a topic of wide importance in most branches of outdoor biophysics, particularly in the measurement of temperature. Almost every temperature measurement involves an uneasy compromise between adequate shielding from radiation and adequate exposure of the element to the environment. A section on the micro-meteorology of meteorological instruments would be a very welcome addition to a future edition of the book.

The remaining three chapters of the book take the mathematical analysis of the first part into the field to match formulae against facts. Temperature distribution and heat flow are considered after a preliminary survey of the heat balance at the earth/air boundary; from temperature, on to wind, with details of wind profiles over rough surfaces and the influence of atmospheric stability on them. Read in conjunction with his earlier chapter on turbulent flow, this chapter justifies Dr. Sutton's statement that there has been much energy spent and ingenuity exercised in investigating problems of wind structure. Has it been overdone? The author's reply would doubtless be to ask the questioner to re-read his final chapter to find there how all that has gone before

can be used in solving problems of dispersal of smoke and other forms of atmospheric pollution, and in providing complete, if complex, expressions for evaporation-rates from open water. These expressions would have much greater practical value if they were accompanied by short tables giving a range of values of the stability-dependant constants that appear in equations 8.55, 8.56 and elsewhere: not everyone who will want to use this chapter will possess tables of incomplete gamma functions or know where to find them.

For a summary impression of the book as a whole we can go back to its beginning. It is dedicated to Sir David Brunt: it is a worthy offering.

H. L. PENMAN

SELECTIONS FROM THE WORKS OF C. G. JUNG

Psychological Reflections

An Anthology of the Writings of C. G. Jung. Selected and edited by Jolande Jacobi. Pp. xxvii+342. (London: Routledge and Kegan Paul, Ltd., 1953.) 30s. net.

THIS anthology of Jung's writings, compiled by Dr. J. Jacobi, is a bedside book: "The object is to show by means of a cross-section a few of the more important aspects of existence reflected in humanity in general, when understood and illuminated by Jung's Psychology. It was not the intention to present Jung's theory; therefore everything which is technical has been excluded".

The publishers recommend this book "not only for the use of scientists, but for all who want to arrive at a better knowledge of themselves and the world". They are presupposing that there is a discovery to be made which is not only scientific discovery—discovery by observation and deduction therefrom in strict accordance with logical rules—but also a discovery by reflexion, a moral discovery.

The whole work of Jung as a man of science poses the question of validation. If the basis of science turns out to be 'unscientific' and 'facts' are as indeterminate as any symbolical experience, then we have to admit that Prof. C. A. Coulson is right when he states that facts say nothing at all; what matters about truth is not the facts, but the interpretation of the facts.

Just as, in physical science, concepts like atoms and electrons are logically unobservable but are validated by analogy, so it is with the working of the mind. What are being experienced there are not fixed things but reflexions of experiences which manifest themselves in symbolical terms. Man to-day, however, is conditioned by his 'scientific' training to think quantitatively and forgets that validation is experienced also in image thinking. Verbal thinking and image thinking go side by side, and Prof. H. H. Price says in his book, "Thinking and Experience" (p. 252): "If rainbows, reflections, mirages and the like had been less common than they are, philosophers would have denied their existence on *a priori* grounds. For how can there be entities which are at once physical and non-physical, in the physical world and yet not of it, existing from some points of view and not from others, spatial but lacking backs or insides? The fate of mental images, in these latter Verbalistic days, has been somewhat

similar. We have the misfortune to live in the most word-ridden civilization in history where thousands and tens of thousands spend their entire working lives in nothing but the manipulation of words. The whole of our higher education is directed to the encouragement of verbal thinking. Let us hope that our successors will be wiser, and will encourage both".

It is with image thinking that Jung's work is concerned. Those who are not too much bogged down in verbal logic, and thus able to experience that there is active also a process of imaging in man's faculties of cognition, will be able to appreciate the significance of this book. The anthology is a useful introduction to the rest of Jung's work. It shows clearly the fundamental weakness of Jung's psychology, which by having no fixed scheme appears to be full of contradictions and paradoxes; but this weakness is at the same time a sign of its greatness. For, life in the psyche manifests itself thus: "You cannot step twice into the same river, because fresh waters are ever flowing in upon you". H. WESTMANN

THE PROGRESS OF PLANT PHYSIOLOGY

Annual Review of Plant Physiology

Vol. 4. Daniel I. Arnon (Editor). Leonard Machlis (Associate Editor). Pp. x+453. (Stanford, Calif.: Annual Reviews Inc., 1953.) 6 dollars.

NOTHING could emphasize more strikingly the rapidity of the growth in knowledge of the physiology of plants than the "Annual Reviews of Plant Physiology" published under the general editorship of Dr. D. I. Arnon and Dr. L. Machlis. No longer can the plant physiologist, by the reading of original papers only, hope to keep up to date with all the aspects of his subject, and all students and teachers of plant physiology should feel grateful to the editors, contributors and publishers of these reviews for making it possible for the generality of plant physiologists to obtain a reasonable appreciation of the work done in those branches of the subject outside their own specialist interests. Each annual volume, four of which have appeared at the time of writing, does not attempt to cover the whole field of plant physiology, but contains a number of reviews, fifteen in each of Volumes 3 and 4, written by authorities in their respective fields, of a limited number of particular aspects of the science, those which are undergoing rapid development being dealt with more frequently than those which are attracting less attention as current subjects of research. Thus, photosynthesis was dealt with in 1952 by E. Rabinowitch, while in the 1953 volume it is reviewed by A. H. Brown and A. W. Frankel and reviews on certain aspects of photosynthesis by D. Burk and L. R. Blinks are promised for 1954. On the other hand, a number of topics such as the physiology of root growth, the biogenesis of terpenes, the plant sterols and fluorescent substances in plants by H. Burström, A. J. Haagen-Smit, W. Bergmann and R. H. Goodwin respectively are reviewed in the 1953 volume but are not in the list of subjects for 1952 or 1954. This policy would appear to be a wise one, for it has the result that each branch of the subject considered contains enough material for an article of reasonable length the writing and reading of which are worth while.

Among articles in the 1953 volume dealing with plant metabolism, apart from those already mentioned, is one by J. G. Wood on the nitrogen metabolism of higher plants in which recent work on the path of nitrate reduction and protein synthesis in plants is adequately summarized. Another aspect of plant metabolism attracting much interest at the present time, namely, the part played by organic acids in metabolism, is ably reviewed by R. H. Burris, while the important question of the use of respiratory inhibitors is exhaustively dealt with by W. O. James, who refers to no less than 247 contributions bearing on this subject. A valuable review on haematin compounds in plants is the work of R. Hill and E. F. Hartree. This includes an account of the distribution of haematin compounds in plants with some remarks on the possible part played by these substances in photosynthesis, a discussion on the cytochrome system as a terminal oxidase in plant respiration, the role of this same system in salt respiration, the function of haemoglobin in the root nodules of the Leguminosae, and an account of recent work on catalase and peroxidase.

Reviews concerned with the popular topics of growth substances and herbicides are contributed by H. Veldstra and A. S. Crafts respectively, while the physiology of fruit growth, a subject about which not a great deal is known, is dealt with in a stimulating review by J. P. Nitech.

The remaining reviews which make up the 1953 volume are on the physiology of mycorrhizal relations in plants by E. Melin, the effect of temperature on plant growth by F. W. Went and the physical properties of protoplasm by H. I. Virgin.

The enormous amount of literature reviewed in a single volume and the high standard maintained generally by the various contributors make these annual reviews a most valuable addition to the literature of plant physiology. They are, indeed, a necessity to the plant physiologist who means to keep abreast of advance in knowledge of his subject.

W. STILES

RECENT ADVANCES IN SPELEOLOGY

British Caving

An Introduction to Speleology. Edited by O. H. D. Cullingford. Pp. xvi+468+48 plates. (London: Routledge and Kegan Paul, Ltd., 1953.) 35s. net.

THE publication of this book marks a conspicuous advance in the study of British caves and shows that modern cave exploration must be regarded as something more than a 'sport'. Hitherto, much material of scientific value about limestone caves has remained either unpublished or hidden away in the little-known journals of local caving clubs. The collection of this scattered information, together with an introduction to the many problems with which caving is concerned, has now been attempted by fifteen members of the Cave Research Group. This Group was formed in 1947 to further "the study of all scientific aspects of cave exploration"; "British Caving" is the Group's first major publication, and is also the first book to cover comprehensively the chief aspects of British caves and caving. Its aim is twofold; first, to give an account of the recent work on caves and the advances in caving techniques;

secondly, to provide, for the rapidly growing numbers of cave explorers, with little or no scientific training, both a guide to the organization of caving and to scientific methods of observation.

The book is divided into two parts. Part I is the larger and is called the "Science of Caving". In this part, Dr. Warwick summarizes the many problems connected with the origin of limestone caves and with the relationship of the caves to the surface land-forms; he also contributes a chapter on the main characteristics of the caving regions of the British Isles. Dr. Wilfred Jackson's contribution is a detailed account of the British caves from which archaeological remains have been obtained; its value is mainly bibliographical and the chapter contains an extremely useful list of the museums where the various 'cave finds' can now be examined. Miss Hazelton and A. E. Glennie have written a section on how to observe and to collect cave fauna and flora; a comprehensive list of the fauna and flora so far recorded from caves in the British Isles is also included. A fascinating chapter, illustrated by a series of fine photographs taken by J. D. H. Hooper, describes the studies now being made in south Devon on cave-dwelling bats. Chapter 7 briefly mentions certain physical aspects, such as air currents and temperatures, the tracing of water-flow under ground and geophysical methods of locating caves. Finally, there is a chapter on the caves associated with lead mines; this is, however, rather slight and is in many ways not up to the general scientific standard of this part of the book.

Part 2 deals with the "Practice of Caving". There is a short note on the history of cave exploration and this is followed by discussions of the equipment and of the procedure and safety precautions necessary in any cave investigation. The chapter, by F. G. Balcombe, on the history and work of the Cave Diving Group is one of the most exciting stories to be told in modern caving. Part 2 also contains clearly written instructions and suggestions on cave photography and on cave surveying. An appendix gives a list of the caving organizations in the British Isles and a glossary of some of the terms used in connexion with caves and limestone areas.

The book is very readable, though as might be expected in a compilation there is considerable unevenness in the treatment of the different topics, and occasionally an incongruous mixture of styles. Moreover, the book covers a field so wide that unavoidably many geological and other problems have to be over-simplified. Full bibliographies at the end of each chapter partly overcomes this defect. Many of these bibliographies would be of greater use if they were more selective; since, also, the literature about caves is of very varying quality, annotation would help the beginner both to acquire the basic scientific knowledge and to discriminate between the useful and less useful references. The reviewer also regrets the substitution of the American words *cadose* (above the water-table) and *phreatic* (below the water-table) for the English terms long in use by British geologists.

"British Caving" is well printed and produced and contains about eighty photographs and many clearly drawn maps and diagrams. The book is indeed a tribute to the amount of solid work put in by the Group; it should introduce many, as its writers hope, to the wonders of limestone caverns, but what is probably more important is that it should establish speleology as a well-defined branch of modern natural history.

M. M. SWEETING

THE EXPERIMENTAL STUDY OF SPEECH*

By DR. D. B. FRY

Department of Phonetics, University College, London

THE speech process consists of a series of transformations, from the stage of the linguistic memory through nervous and muscular activity to that of variations of air pressure and then back again. The purpose of the experimental investigation of speech can be summarized as the study of these transformations, the establishing of correlations between events at each succeeding stage, and the examining of the form of these correlations.

In recent years, the study of speech has been influenced by new points of view and by the development of new experimental methods for exploring the correlations between the linguistic, the physiological and the physical aspects of speech. Experimental research by its very nature imposes an operational view of the subject-matter to be examined, and the adoption of such a view of speech might at first appear to preclude work on certain of the linguistic aspects of speech such as 'meaning'. It is quite possible, however, to explore experimentally the associations of words and other linguistic units for different individuals. Lenneberg¹ has done some research, for example, on the associations of words for colours. He presented a number of subjects with a great variety of different colours, varying the hue and the brightness in a systematic way, and then correlated the words used by the subjects to denote the colours with the variation in the stimulus. In these experiments there is a very obvious physiological component; subjects who have some degree or type of colour blindness are likely to have fewer associations in common with the rest of the population, though they may show a good deal of agreement among themselves. The results in general showed that the degree of agreement between individuals varied as the stimulus was changed: there were a number of points of maximum agreement, at some of which the subjects were unanimous in their choice of a word—thus for some particular colour everyone used the word 'red'; then as the stimulus was changed in a given direction, gradually a greater diversity of words was used. In addition to this general pattern of agreement, it was possible to see fairly systematic variations of association according to the background of the individuals.

What is usually referred to as the meaning of a term is therefore from this point of view the total of the associations held in common by the majority of the users of the term. Experimental work based on this point of view is naturally most easily carried out on the associations of concrete words. Although the extent of the linguistic material that can be explored in this way is obviously limited, the results do shed some light on the way in which this part of the speech process works, and by the use of such methods the semantic factor in speech can be brought within the range of experimental work.

Another important feature of the linguistic aspect is the influence of context. At the phonemic level, the effect of context is generally viewed nowadays in terms of communication theory. Shannon's con-

clusions about the statistical structure of written English² are applicable to the sound system of a language. The experiment in which he asked a subject to guess the sequence of letters in an English sentence can be repeated with the sounds of spoken English, provided the subject has had enough phonetic training to think in terms of sounds rather than letters. The technique is to choose a sequence of English sounds forming a sentence and then to ask the subject to guess each successive sound. The number of guesses required to arrive at the correct sound shows considerable variation. At the first position the number is high, and it shows in general a gradual decrease as the sequence proceeds; within this general trend, there are smaller rises and falls at succeeding points in the sequence, the peaks of uncertainty usually falling at or near word or syllable junctions. These results have encouraged several workers to explore the usefulness of distributional criteria as a basis for defining linguistic units³.

In investigating the function of the nerve connections in speech, a valuable step forward has resulted from the study of feed-back mechanisms and the part that they play in the speech process. The methods used depend in every case on some interference with the feed-back—interference which may be temporary and artificial, or the result of a pathological condition and more or less permanent. For example, the case of the congenitally deaf child is more clearly understood, since the enormous importance of the auditory feed-back for speech has been appreciated. The training of such children is seen to require first and foremost the provision of any degree of auditory feed-back that is possible for the particular child, and then the supplementing of this by the use of visual, tactile and kinaesthetic feed-back.

The methods of interfering artificially with the feed-back circuits have been concerned with the auditory feed-back, and have consisted in either obliterating the feed-back altogether, or in delaying it. This interference is possible because, when we sing or speak, most of the sound which we ourselves hear is conveyed to our ears by bone conduction. The bone-conducted sound can be completely masked by supplying to the ear some other sound of sufficient intensity by air conduction; the latter may be a very loud masking noise, which obliterates the auditory feed-back altogether, or it may be the subject's own speech (or singing) delayed by some time interval. One of the effects of obliterating the feed-back altogether, for example, is that the mechanism which controls the pitch of the singing voice no longer functions properly and the subject can no longer sing in tune. When the feed-back is delayed, the effect upon speech is very dramatic. It appears that the speech mechanism is very sensitive to delay in the auditory feed-back, at least over a certain range of delay times. The effect produced varies with individuals and with the delay time; but it generally takes the form of an artificial stammer, and the speaker in this condition feels himself under considerable nervous stress.

* Substance of a lecture delivered in University College, London, on March 16.

Experimental evidence about the functioning of muscular systems has been obtained in recent years largely by means of photographic methods. The change from muscular movements to wave motions in air is one which we should expect to yield a close correlation between the two sets of events, and for this reason many attempts have been made to obtain a more exact record of these movements both at the level of the larynx, which may be regarded as the primary generator of the wave trains of speech, and also at the level of the articulatory mechanism which modifies the output of the larynx. High-speed direct photography has been applied to the study of the functioning of the larynx at the Bell Telephone Laboratories, where for the first time some of the modes of vibration of the vocal cords have been recorded; this work has provided evidence of the relative times of the open and closed phase of the cords, which are seen to vary with individual speakers and with the fundamental frequency of the vibration. This matter is of considerable importance to any attempt to calculate the physical output of the speech mechanism from a consideration of its physiological and anatomical properties. Still further evidence about laryngeal functioning has resulted from the improved X-ray photographic techniques which are now available. The internal action of the larynx was for a long time inaccessible to X-ray photography, but the development of the tomogram technique has enabled Ardran and Kemp⁴ to obtain remarkable records of the larynx in action. The evidence which they offer concerning the sphincteric action of the larynx may well lead to a reconsideration of the way in which this part of the speech mechanism functions.

Photographic methods, both direct and X-ray, have been applied also to the examination of the articulatory mechanism. Films have been taken of subjects in whom some abnormal anatomical condition allows a direct view of parts of the speech mechanism. The first of these, made in 1943⁵, showed the movements of the tongue in the speech of an English subject whose right cheek had been removed surgically. In a more recent film of a similar nature, it is possible to see from above the changes in the disposition of the soft palate during speech. All such records are open to objection on the grounds of the abnormality of the subject, both from the point of view of anatomy and of the acoustic output of his speech mechanism. On the other hand, there is a strong argument for attributing some degree of normality to the movements which we see, since we know that it is very difficult for the adult human being to change his speech movements, a fact which is brought home afresh to anyone who tries to learn to speak a new foreign language.

The physical aspect of speech is much more accessible to experimental study than the linguistic and physiological aspects, and it is possible to give a very full description in physical terms of the wave motions of speech. The difficulty consists in establishing the correlations between features of the wave-motions and the perception and understanding of speech by the listener. The classic view of the problem was that speech sounds consisted, physically, of a more or less rapidly changing complex of frequencies, among which a few high-amplitude components, called the 'formants', were responsible for the discrimination of different sounds by the listener. Hence the most favoured method of examining the speech wave-motions was by a process of frequency

analysis which would lead to the detection of the formants. A system which is particularly adapted to this purpose is the one which was at first labelled 'visible speech'. This was developed by the Bell Telephone Laboratories⁶ during the war years and is essentially a conventional system of frequency analysis; its new feature is the provision for presenting the analysis extended along the time axis. The output of the system generally takes the form of visual patterns, known as 'spectrograms', in which time is represented on the horizontal axis, frequency on the vertical axis, and the relative intensity of the frequency components is indicated by the gradation from black to white in the pattern.

Many people have, in recent years, come to the conclusion that frequency analysis, in its classical form, is not the real basis for recognition, and have sought to develop other methods of inspecting the speech wave-motions. It has been suggested, for example, that the discrimination of sounds might depend on the perception of differences in the frequency with which the wave-form crosses the zero line, and that all speech sounds might be recognized on this basis. It is possible by electronic circuits to transform the speech waves in such a way that each zero-crossing is represented simply by a pulse, and these pulses can be counted electronically in order to arrive at the frequency of zero-crossings for given unit times. The first important result obtained by this method⁷ was the demonstration that if the pulses themselves were simply transformed into acoustic wave-motions, they constituted sounds which were perfectly intelligible as speech to the ordinary listener, thus showing yet again that speech is extremely resistant to a great variety of distortions. In addition to this, many experiments have been made in which the zero-crossings have been, so to speak, re-arranged: they have been averaged over various time-intervals; they have been spread out and condensed along the time axis; the negative-going pulses have been omitted altogether and have also been replaced by positive-going pulses with very interesting results; the form of the variation in zero-crossing frequency for different speech sounds has been closely examined. The results of many of these experiments have not yet been published; but up to the present there appears to be no very strong evidence that any method of treating the zero-crossings yields results showing an appreciably closer correlation with the linguistic units than the results of more conventional systems of frequency analysis.

All these ways of inspecting the speech wave-motions aim at discovering the perceptual-physical correlations by transforming the wave-motions in a variety of ways in the hope of finding one method which will give the desired correlations. An alternative to this method is the use of a speech synthesizer, a machine which will generate speech-like sounds of a relatively simple physical nature and by means of which the effect of single physical clues to the primary recognition of sounds may be explored. A number of such synthesizers are now in use and many interesting results have already been published. Liberman, Delattre and Cooper⁸, using a synthesizer which produces sounds from simplified spectrograms, have shown that a short burst of sound lasting about 15 msec. and covering a narrow frequency-band will be recognized as a consonant of the plosive type when it is combined with a vowel-like sound. In one series of experiments, the location of this burst on the frequency-scale was taken as the

single physical clue, and it was found that listeners judged the consonant to be *p*, *t* or *k*, depending on the position of the burst and on the vowel with which it was combined. A second series of experiments was concerned with another clue which appears to be important for the primary recognition of consonants¹. This is the 'formant transition'—the way in which the frequency of a formant changes in the course of a syllable. Synthesized sounds consisting of two formants the frequency of which remained constant throughout were recognized by listeners as single vowels; if, however, the formant frequency was changed fairly rapidly during the first 50 msec., the listener heard the vowel preceded by a voiced plosive consonant. The direction of the frequency-change, its extent and the particular vowel sound concerned, all combined to determine whether this consonant was *b*, *d* or *g*.

In further experiments with the same synthesizer, Denes¹² demonstrated the importance of time-relations for the primary recognition of speech sounds. Listeners judged a fricative sound to be either *s* or *z* according to the ratio of its duration to that of a preceding vowel. When the fricative was short compared with the vowel, the majority of subjects heard *s*; and these judgments changed in favour of *z* as the friction was made progressively longer compared with the vowel.

Time relations were again shown to be an effective clue for recognition by work which I have carried out¹³. The object of these experiments was to test the effect of the ratio of durations and of intensities as clues for discriminating between stressed and unstressed syllables in English. The material used for this study was a group of words like 'object' in which, for most speakers, a change of function from noun to verb is accompanied by a shift of the stress from the first to the second syllable. Many different versions of each word were synthesized in which the ratios of durations and of intensities of the two vowels were varied over a considerable range. Listeners were then asked to say whether they recognized the noun or the verb form in each case. The results of this test showed that both duration and intensity operated as clues for recognition, but that the duration clue was much the more effective. The whole range of intensity-changes was responsible for a change of only 27 per cent in listeners' judgments, whereas the range of duration changes produced a change of 71 per cent.

This experimental procedure, which makes it possible to examine the operation of physical clues separately, has already done a great deal to make clearer the general nature of the recognition process, and to suggest the terms in which it may be possible in the future to state the very complex correlations that exist between the perceptual and the physical in speech.

GOETHE'S SCIENTIFIC BACKGROUND

IT has been said that, whereas we know next to nothing about Shakespeare's life, almost too much is known about Goethe's. His autobiography, diaries, correspondence, carefully recorded talks, and innumerable scattered notes which were never meant for publication, provide such an inexhaustible wealth of material that any exegete intent on emphasizing a special tendency in Goethe's mind could produce some evidence for his thesis if he is willing to spend enough time on the perusal of every available source.

A recent book by Dr. Ronald D. Gray on "Goethe the Alchemist"^{*} sets out to show "that Goethe was profoundly influenced throughout his life by the religious and philosophical beliefs he derived from his early study of Alchemy". It is a very learned book, so rich in not easily accessible material that admirers of Goethe will study it with pleasure and profit, even though they may be unable to agree with the author's opinion.

Goethe's interest in alchemy is well known to every reader of "Faust"; it may even be correct to say that all that the average educated German knows about alchemical imagery is contained in the few very colourful and impressive lines in which Faust describes the laboratory experiments of his deceased father. From the second part of "Faust", many will remember also the alchemical origin of Homunculus. It is certainly a merit of the author to have searched with enormous industry for further alchemical ideas and symbols not only in Goethe's lesser-known poetical works but also in his scientific writings, and much of what he has to say about alchemical reminiscences in Goethe's "Farbenlehre", his "Metamorphose der Pflanzen", and his anatomical, geological and meteorological papers, will strike the reader as worth pondering about; but it is usually far from convincing.

A great deal has been written about Goethe's strange theory of the origin of coloured light and his stubborn refusal to listen to any German defender of Newton's explanation. To Goethe, his theory of colours was much more than the solution of an isolated problem in physics; it was, as has been shown by many writers, intimately connected with his personal way of searching for explanations of natural phenomena; but whether we can see in his colour-theory as close a connexion with alchemy as Dr. Gray suggests is quite a different question. He wants to make us believe that the empirical appearance of Goethe's colour-theory is only "superficial" and that, first of all, it had to conform with alchemical doctrine, with the colour changes described by alchemists as essential for their 'Great Work'. Considering the small number of the six or seven rainbow colours mentioned in alchemical writings, occasional similarities with Goethe's statements will not surprise us—all the less, since the alchemists, like Goethe, were starting from actual observations, and many of them were by no means so completely lost in symbolism as readers of some recent books, for example, those by C. G. Jung, may believe. The influence on Dr. Gray of Jung's re-interpretation of alchemy is very obvious, and he goes even further in the same direction in his attempt to show that in Goethe's

^{*} Goethe the Alchemist: A Study of Alchemical Symbolism in Goethe's Literary and Scientific Works. By Ronald D. Gray. Pp. x+312+3 plates. (Cambridge: At the University Press, 1953.) 35s. net.

theory of colours, too, not the experimental content but the symbolism is essential; but it is almost inconceivable that anyone could get such an impression who studies Goethe's work without a preconceived idea. With infinite patience experiment after experiment was described by Goethe, and the reader exhorted to repeat and check them; this has been done by many who have realized with admiration that Goethe, whose colour sense must have been of a very high order, was not only extremely accurate in his descriptions but was also sometimes even the first to notice some delicate phenomenon. To the countless experiments and historical studies connected with his theory of colours, Goethe devoted probably more effort than to any other single work.

Goethe himself was very careful to draw a clear line between the scientific part of his theory, which he was confident could by experiments be demonstrated to be superior to Newton's, and the entirely different concluding section on "the sensorial and moral effect of colour" ("Sinnlich-seitliche Wirkung der Farbe"). This subject is naturally quite different; here Goethe the artist is speaking, and it is very unfortunate that without warning to his readers Dr. Gray mixes the quotations from both parts. Right at the end of this last section, one or two pages are devoted to the "Allegorical, symbolical and mystical use of colours". Here Goethe declares that he did not want to be suspected of mysticism ("Schwärmerei") and predicts that, according to the fashion of his days, there would anyhow be no lack of allegorical, symbolical and mystical applications of his theory. This remark is no encouragement for such attempts, and Goethe did not foresee that he might have to fear even an alchemical interpretation, such as presented now in Dr. Gray's book. As "final evidence" for his thesis, Dr. Gray quotes a passage in which an old anonymous writer says that his remarks about colours "can be combined with the secret philosophy and experience of the chemists", a passage republished by Goethe in one of his occasional minor writings; we are told that this is "the frankest declaration on Goethe's part of the fact that his Colour-Theory was only to be fully understood in terms of alchemical symbolism". If that is the frankest, our doubts are scarcely dispelled as to whether the author is on the right track, or whether he is perhaps deluding himself when he believes he notices everywhere in Goethe's theory of colours the smell of alchemy.

Discussing the meteorological images in Goethe's poetry, Dr. Gray quotes a passage from the final scene of "Faust II" where clouds change into a host of blessed spirits. "The immediate source of this image can be traced back to a moment of Goethe's life some fifty years before those lines were written"—so we are told, and a remark is quoted from a letter written in the far-distant days when alchemy was still near to Goethe's heart. Now for the modern author, who has all Goethe's works simultaneously available, this source may appear "immediate"; but for Goethe himself a letter written to a friend fifty years earlier can scarcely have been an immediate source, nor is it likely that just one, not at all unusual, observation of so long ago was still present in his memory.

It is not to be expected either that the alchemical explanation of the *Urpflanze*, to which Dr. Gray devotes much space, will convey conviction to many. We are informed that the stages of this hypothetical plant correspond to Boehme's "Seven Qualities of

God", and in some of the stages no doubt resemblance can be found; but it is only "by ignoring Goethe's definite statement that there are six stages in the life of the plant, and including what he omitted, the original seed" that it was possible for the author to establish "a very close parallel with mystical doctrines". Here again we meet the usual trouble: Goethe was careful "to publish only the barest hints. The passages which most reveal his thoughts are found almost entirely in his private notes or in later publications".

It must be conceded to Dr. Gray that, although it was his professed task to go so far as possible in an attempt to follow up in Goethe's works alchemical influences, he nevertheless sometimes shows restraint, when we are already fearing the worst. We are certainly grateful to him that, after drawing "Iphigenie" into a chapter on Amazons, hermaphrodites and the symbolism of the "male and female" in alchemical writings, he assures us that in spite of "the union of opposites, sun and moon, brother and sister", which provides a happy conclusion of the play, "it would be absurd to claim Iphigenie as an example of Goethe's use of alchemical symbolism". Mignon is not so fortunate; she is plainly called a hermaphrodite, although Dr. Gray admits that she is not quite so perfect a being as this—in alchemical parlance—very laudatory expression indicates. On the other hand, one feels again relieved when the sentence "it would make for a neat interpretative pattern if one could agree with C. G. Jung that the whole of Faust II is a poetic representation of the alchemical work", is followed by a "but"; one would wish, however, that here the author's objection was not confined to the lack of alchemical symbolism in the third act of "Faust II", but that he would say in so many words how pointless the whole "Faust II" would appear to most of us if Goethe's ambition had really been what Jung supposes; we should be inclined to say, in Mephisto's words, "ein grosser Aufwand, schmachlich, ist vertan".

Dr. Gray is so convinced that the expressions Goethe uses in the description of natural phenomena must come from the writings of the alchemists, that he assumes such a parallel even if he has no proof at all to offer. Goethe believed that the crystallization of rocks was accompanied by a tremor; the author admits that here the parallels with alchemical literature "are not as close as one could wish", but he "feels" that some of the alchemists "also must have used such expressions" for their process, although he has "not chanced to come across any such passages". Why should we look for such a distant and purely hypothetical source of Goethe's views if (in a paragraph quoted in the present book) he refers to the simple observation that "water in a vessel, on the point of freezing, is transformed by the slightest shock into solid ice"? Let us not forget that if Goethe was anything in science, he was a brilliant observer. For a similar reason, there can be no necessity at all for assuming that, when Goethe likened little clouds to white doves, these birds must have been reminiscences of alchemical symbols he had come across in his youth, and that only "later he came to feel that Nature herself offered such symbols in plenty". After all, he was a poet too.

It is to be hoped that no reader of this book will forget that its aim is to bring out certain aspects of Goethe's *Weltanschauung* by sharply illuminating them from a certain angle, and that by this process other features are necessarily obscured. The study

of "Goethe the Alchemist" should be followed by the reading of books with titles like "Goethe the Classicist", "Goethe the Spinozist" and, most necessarily, "Goethe the Scientist". The author himself is helpful here in providing a list of "Books and Articles consulted", which comprises, in the section entitled "Goethe's Science", some fifty authors. Three very valuable contributions to the subject are, however, missing: Helmholtz's and Tyndall's well-known studies on Goethe's scientific work and—less astonishing, but still more regrettable—O. G. Carus's little book "Goethe" (Leipzig, 1843). For anyone who has ploughed his way through the complicated symbolism attributed to Goethe in Dr. Gray's book, it will be most refreshing and clarifying to read Carus's chapter on "Goethe's Relation to Nature and Science". Discussing his various contributions to science, Carus gives pride of place to the idea of the *Urpflanze* which had been "of the highest and most enlivening effect on the whole field of botany". (Similar praise is bestowed on his anatomical ideas.) Is it likely that a revival of Boehme's and other alchemists' and mystics' abstruse ideas, "a cunning and intricate pattern of metaphor and simile, elaborated down to the smallest detail"—as Dr. Gray calls Goethe's botanical theory—could have had such a beneficial influence on the progress of modern science? I believe it to be very significant that neither in this chapter, nor in the one which attempts to explain Goethe's works "from an understanding of his personality", are alchemical interests mentioned by Carus even once. He must be considered as one of the most competent judges, as he knew Goethe personally, enjoyed his affection and respect as shown in their correspondence and had many scientific and artistic interests in common with Goethe, being himself eminent in such various fields as anatomy, psychology, philosophy and painting. If Carus, in his explanation of Goethe's scientific background, could leave out alchemy completely, one's suspicion is strengthened that Dr. Gray's point of view is only the purely literary and utterly non-scientific attitude of a late interpreter, and that it is the arbitrary emphasis which he lays on a few of the remotest of Goethe's utterances that makes the alchemical influence appear of such over-riding importance.

We are nevertheless indebted to Dr. Gray for having spent so great an effort on the pursuit of this single line of research, and for having collected the scattered material in a very original book.

F. A. PANETH

VERTEBRATES WITHOUT ERYTHROCYTES AND BLOOD PIGMENT

By PROF. JOHAN T. RUUD

Biologisk Laboratorium, University, Oslo

IT is frequently claimed that one of the characteristics of vertebrates is that they have a red blood pigment, hemoglobin. Exceptions are the *Leptocephalus*-larva of the eel, which has no blood pigment until it develops into an elver, and *Petro-myzon*, which has a blood pigment slightly different from that of other vertebrates.

For half a century, however, whalers in South Georgia have known that there are three local species

of fish, namely, *Champscephalus gunnari* Lonnberg, *Pseudochaenichthys georgianus* Norman, and *Chaenoccephalus aceratus* (Lonnberg), all of which have a colourless blood. The Norwegian whalers call them "bloodless fish" (*blodlaus-fisk*).

I first heard about these "bloodless fish" on a visit to South Georgia in 1929; but no specimens were forthcoming, and I did not take them seriously. I was reminded about their existence, however, when Mr. D. Rustad, biologist in the Norwegian Expedition (1927-28), presented me with some photographs of a "white crocodile fish" caught by him at Bouvet Island, mentioning the fact that its blood was colourless. From these photographs Nybelin¹ in 1947 described the fish as a new species, *Champscephalus bouvetensis*, believing it to be distinct from *C. aceratus* known from South Georgia and other west Antarctic islands. Nybelin cites the description communicated to him by Rustad, in which we find the remark: "Blood colourless". Farther on he says about the South Georgia species that it "is said to have colourless blood" (ref. 1, p. 51). So far as I know, this is the first time the fact is mentioned in the literature. (After this was written my attention was directed to a book by L. Harrison Matthews, "South Georgia, the British Empire's Subantarctic Outpost", published in 1931, in which the author on p. 36 mentions the fact that a species of fish with white gills and colourless blood exists in South Georgia.)

I heard about colourless blood in fish again when Mr. Fredrik Beyer, biologist in the Norwegian Bratag expedition (1947-48), returned home with some specimens of *Champscephalus esox* (Günther) taken by him in the harbour of Punta Arenas. In his paper on the fishes from this expedition, Nybelin cites Beyer's description: "The gills colourless on the living animal" (ref. 2, pp. 9-10).

When Mr. Steinar Olsen was sent to South Georgia to conduct some investigations on the "South Georgia ood" *Notothenia rossi marmorata* Fischer, I asked him to look out for the fishes with colourless blood, and he returned in 1951 with some preserved specimens of the fishes and samples of their blood frozen and fixed in formalin.

Prof. P. A. Owren (Medisinsk Avd. A., Rikshospitalet, Oslo) prepared blood smears from these samples and stained with May Grünwald and Giemsa. He found no cells resembling erythrocytes; but a few nucleated cells, presumably lymphocytes, were present. No blood pigment could be demonstrated in these samples, and their fixed condition prohibited a closer study of the blood proteins.

In December 1953, after the whaler *Enn* had completed her international whale-marking voyage at South Georgia, I was able to make some determinations of the oxygen capacity of the colourless fish blood. Steinar Olsen had told me that in the Antarctic midsummer I could expect to catch only one of the three species known to occur in South Georgia, namely, *Champscephalus aceratus*, known to Norwegian whalers as the "white crocodile fish" and to British whalers as the "icefish", probably because it is nearly transparent.

Indeed, I would not have succeeded in catching this species either, were it not for the unfailing help of Mr. Sigvald Sørensen, storekeeper at Husvik Harbour, and of Dr. D. Felix Richards, physician at Leith Harbour. I am indebted to the managers of both whaling stations, Mr. Nils E. Olsen, of Husvik, and Mr. S. L. Bjelland, of Leith, for facilities liberally placed at my disposal.

The oxygen capacity of the blood was determined by the micro-gasometric method described by Roughton and Scholander³, with certain modifications necessary for working on fish blood, kindly communicated to me by Dr. Scholander just before my departure from Norway.

I secured four specimens of *Chaenoccephalus aceratus* in all, the first three shortly after my arrival to South Georgia and before I was fully prepared to make the analyses. My first analysis was made, therefore, on blood which had been stored for some days in a refrigerator. Later I obtained the fourth specimen and could repeat all observations on freshly drawn blood, taken from the ventricle of the heart with a syringe in which the dead-space had been filled with heparin to prevent clotting.

The freshly drawn blood is nearly transparent, with a slight yellowish-white tint. Without the addition of some anticoagulant it clots in the course of two or three minutes to the consistency of a soft jelly.

After being centrifuged for 30 min. at 3,500 rev./min., the plasma is clear as water, and the sediment of white cells constitutes less than 1 per cent of the volume.

No absorption band can be discerned in a spectrum.

Blood smears stained with May Grünwald and Giemsa confirmed the previous observations, that there are no blood corpuscles similar to the erythrocytes of normal vertebrate blood.

Before determining the oxygen capacity, the blood was aerated for 15-50 min. in a container open to the air and revolving slowly around a horizontal axis.

The blood from the first three fish had been mixed and kept in a refrigerator for five days before the oxygen capacity was determined. The colour of this blood seemed to be unaltered and it smelt good, but a little 'fishy'. Four determinations gave an average of 0.67 per cent by volume of oxygen in the range 1.08-0.45.

The average of eight analyses of the freshly drawn blood from the fourth specimen gave 0.72 per cent oxygen by volume (range 0.90-0.54). What was left over from this sample was used as a check on the earlier determinations by keeping it in a refrigerator for five days and then making three further analyses. These gave an average of 0.77 per cent oxygen by volume (range 0.945-0.675), which is slightly more than on the first occasion.

For comparison I determined the oxygen capacity of normal red blood from two other local species of fish, *Notothenia rossi marmorata* Fischer and *Notothenia coriiceps* Richardson. They gave mean values of 5.99 and 6.24 per cent by volume of oxygen, respectively, capacities of the same order as those known from northern fishes.

The oxygen capacity of the blood of *Chaenoccephalus aceratus* is presumably not more than what one would expect to find in the plasma alone of ordinary red blood. It seems evident, therefore, that *Chaenoccephalus aceratus* has no means of taking up oxygen in its blood except by physical solution.

A small sample of the blood was taken back to Norway stored in a refrigerator. From this sample, which was now slightly decomposed, Dr. Ernst Fåyn, of this Laboratory, has determined the iron content according to the method described by Wong⁴. He found less than 1 mgm. per cent iron. This result cannot claim to give the true value of the iron

content of the blood of *Chaenoccephalus aceratus*, since the sample had a minute addition of heparin. Van Dam and Scholander⁵ and others have determined the iron content of the red blood of various species of fish and give mean values of 19.6-28.7 mgm. per cent. The result of Dr. Fåyn's analysis supports, therefore, the view that the blood of *Chaenoccephalus aceratus* is to be considered as a plasma with a moderate content of leucocytes.

I had no opportunity of determining the actual metabolism of *Chaenoccephalus aceratus*. One would expect it to be rather low, and the fish seen alive gave the impression of being quite sluggish compared with other species taken at the same time. It seemed to be very sensitive to lack of oxygen, because as soon as it was landed it made laboured respiratory movements, extending its gill-covers as widely as possible, thus displaying the peculiar yellowish-white colour of the gills. I did not measure the respiratory surface of the gills; but they seemed to be relatively big. Such measurements will be made on the preserved specimens.

It should be noted that *Chaenoccephalus aceratus* attains to 60 cm. or more and can weigh more than 1 kgm. The two other 'bloodless' species known from South Georgia are slightly smaller, *Champsoccephalus gunnari* being about 32 cm. long and *Pseudo-chaenichthys georgianus* about 48 cm.

All three species belong to the family Chaenichthyidae, the characters of which include a naked body and ribs not ossified. According to Norman⁶, the family has nine genera with thirteen species, to which belong the species described by Nybelin from Bouvet Island. Thus thirteen are confined to the Antarctic zone. Only one species is found north of the Antarctic Convergence, namely, *Champsoccephalus acaz*, known from the Patagonian coast and the Falkland Islands, which according to Beyer's observations, mentioned above, also has a colourless blood. It seems very likely that other species, besides the three from South Georgia, the one from Bouvet Island and the one from the Patagonian coast, may have colourless blood, but no information is available.

It is little wonder that the colourless blood of these fish has been overlooked by the scientists who described them, because the red gills of other fishes are soon bleached in museum material preserved in alcohol. It is to be noted that Nybelin's observation of the fact is due to statements made by the scientists who made the catches.

The fact that a good-sized vertebrate can exist without any oxygen-binding blood pigment provokes some interesting questions. Since these fish presumably descend from ancestors with haemoglobin in their blood, one imagines that only in the cold water of the polar regions could a fish survive which had lost its blood pigment. The *Chaenoccephalus* specimens came from water at rather less than 2° C. In the winter farther south the water temperature descends to around -1.7°, and is always well aerated. In winter the whalers at South Georgia catch the 'white crocodile fish' more commonly inshore, so *Chaenoccephalus aceratus* tends probably to avoid the higher temperature found in the flocks in the summer and moves offshore.

Concerning the evolutionary problem raised by these fishes without blood pigment, it is interesting to mention that C. Tate Regan (quoted by Norman⁶) considered that "Antarctica may have long been isolated and that its coasts may have been washed

by a cold sea for a long time, probably throughout the Tertiary Period".

PROF. H. MUNRO FOX, Bedford College, London, writes the following comment on the foregoing article: Prof. Johan T. Rund's study of the fishes with colourless blood will be a most interesting surprise to most zoologists, although a few knew of their existence¹. The fact that there are fishes lacking haemoglobin is not, however, quite so astonishing as appears at first sight, for the following reason. More than thirty years ago Maurice Nieuvoort² showed experimentally that carp, pike and eels remained alive for four hours, "*pas très incommodes*", in water through which a mixture of air with 2 per cent carbon monoxide was bubbled. Such a gas mixture would quickly kill a man. The haemoglobin in the fishes' blood was found to be about 90 per cent in the state of carboxyhaemoglobin, that is, incapable of transporting oxygen. The conclusion, although not drawn by Nieuvoort, is that many fishes when swimming quietly get enough oxygen for their needs in solution in the blood plasma, and they probably only require an additional supply with the aid of haemoglobin when they are moving actively. Their haemoglobin is an emergency precaution and the 'ice fish' do without this luxury. Doubtless, however, haemoglobin is not a luxury but a necessity in the blood of such fishes as mackerel, which cannot get enough oxygen without swimming rapidly through the water³.

NEW SURGE GENERATOR AT THE NATIONAL PHYSICAL LABORATORY

By R. S. J. SPILSBURY

ON April 21 a ceremony was held at the National Physical Laboratory to inaugurate the new surge generator installed by H.M. Ministry of Works for the use of the Electricity Division of the Laboratory. The equipment was put into action by Sir Edward Bullard, director of the Laboratory, and caused to discharge across a chain of forty-five glass suspension insulators, the total length between end fittings being 20 ft. Thanks to the courtesy of the main contractors for the equipment, Messrs. Ferranti, of Hollinwood, the inauguration was followed by a luncheon, at which Sir Edward made a short speech, and Sir Vincent Z. de Ferranti replied.

The need for surge generators arises, of course, from the hazards to which overhead electricity transmission lines, and the transformers, cables, etc., connected to them, are subjected when lightning

strikes the conductors or their supporting towers. The effect is to raise the voltage of the line, in a time of the order of a millionth of a second, to a value limited in practice only by the breakdown voltage of some of the insulation, such as air gaps or strings of porcelain insulators: this voltage may be of the order of a million volts for 275-kV. lines. Similar effects occur when switches are operated, though these surges are usually less serious. The voltage step imposed travels along the line without much attenuation, and in due course reaches a transformer or cable. The effect on transformers is particularly serious, since the steep front of the travelling voltage wave causes most of the voltage to appear across the first few turns of the winding, and so to place a stress on the inter-turn insulation many times that which it has to withstand in normal service.

The increasing use of overhead transmission lines and the occurrence of breakdowns due to the causes mentioned above produced, many years ago, a demand for tests designed to simulate the effects of natural lightning, and the surge generator, in conjunction with a high-speed cathode-ray oscillograph, provided the necessary tool. Briefly, such a generator consists of a series of high-voltage condensers which are charged, through fairly high resistances, by a direct-current source of suitable polarity—the effects of positive and negative surges are not, in general, the same—and are then connected in series by the breakdown of air-gaps. The breakdown is initiated by applying a controlled voltage surge to one of the gaps. In this way a voltage impulse, reaching its peak in perhaps a millionth of a second, and decreasing to half this value in about 50 millionths of a second—values which have been internationally agreed as reasonably representative of those which occur in practice—can be applied to a test object.

The National Physical Laboratory has possessed apparatus of this type, built by its own staff, for many years, the open-circuit voltage of the generator being 2 million, and the energy stored in the condensers 20 kilowatt seconds, and, until recently, this has been adequate. Some little while ago, however, it became clear that new equipment was needed; partly because transmission voltages are rising—275 kV. is in use in Great Britain and 380 kV. on the Continent—and partly because the condensers that form the heart of the generator, and are heavily stressed in service, were showing signs of deterioration. It was therefore decided to install new plant, and to design this for the highest voltage that the size of the building allowed—5.2 million volts—so that it would be adequate for the foreseeable future. The dimensions of the main high-voltage laboratory are 120 ft. × 60 ft. × 45 ft. clear height; even so, it was necessary, in order to obtain adequate clearance, to excavate a large pit 8 ft. deep, in which the generator stands.

The apparatus has eight stages, each charged to a voltage of up to 400 kV. by a transformer and metal rectifier: the stored energy is 77 kW. Each stage consists of two condensers in separate housings, the stage capacitance being 0.15 microfarad. The circular ribbed porcelain housings, with empty porcelains to act as stage insulators, are assembled into a strong four-column structure, which also supports the 50-cm. diameter spheres that form the electrodes of the various air-gaps, and resistors for controlling the shape of the voltage impulse. A condenser is provided to form the high-voltage section of a capacitance voltage-divider, from which

the scaled-down voltage that is applied to the recording oscillograph is obtained.

A glass-fronted chamber, built out into the laboratory at the level of the first floor, houses a desk which incorporates all the controls, and the indicators for safety interlocks, etc. The controls include means for varying the voltage, reversing polarity, setting the inter-stage gaps to a value appropriate for the stage voltage in use, firing the generator at the desired instant, and earthing the apparatus between tests. A device is provided for starting the 'time-sweep' of the oscillograph just before the generator fires, so that the front of the wave is properly recorded. The oscillograph is housed in a steel shield near the control desk.

The new generator is believed to be the largest in Great Britain, and it should be a valuable addition to the research and testing equipment of the Laboratory.

harvest of results brought him a well-earned Ph.D. in 1950. The most significant discovery was the recognition of the fact that, although the complex bears the hall-marks of an intrusion (for example, it transgresses the structures of the country rocks and shows internal vertical lineations), the materials of the marginal part of the granitic mass are transformation products of the adjacent country rocks. Rutledge also made an important tectonic study of the Fannich Forest area in the Scottish Highlands. More recently he was engaged on similar tectonic and petrogenetic problems in New South Wales.

A geologist of initiative and distinction, Harold Rutledge was fearless in spirit and endowed with great vitality and power of endurance. His sudden death, just as he was approaching a period of solid achievement, is indeed a grievous loss. Deep sympathy will be felt for his widow and four-year-old son.

ARTHUR HOLMES

OBITUARIES

Dr. Harold Rutledge

DR. HAROLD RUTLEDGE was among the ill-fated passengers who lost their lives when an air-liner en route to London from Sydney crashed at Singapore on March 13. The news of his tragic death at the early age of thirty-three has deeply shocked all who knew him, and not least his many geological friends in Britain and Australia. Born on December 15, 1920, at Fairfield, Darlington, he was educated at Stockton Secondary School before entering Bede College in 1939 as a student of the University of Durham. He was elected senior student of the Science Laboratories at Durham, 1941-42, and obtained a first-class honours degree in geology in 1942. He was no less distinguished in university athletics and games—becoming a rugger blue—while his obvious capacity for leadership was recognized by his appointment as sergeant-major of the S.T.O. After graduation, Rutledge entered the Royal Engineers and was soon seconded to the Royal Bombay Sappers and Miners, 1943-46, with whom he saw active service in the Burma campaign, eventually with the rank of captain.

On demobilization, Rutledge spent nearly a year on the staff of the Atomic Energy Division of H.M. Geological Survey; but wishing to return to academic life, he accepted appointment in 1947 as assistant lecturer in geology at Nottingham. A year later I invited him to join the staff of the Grant Institute of Geology, University of Edinburgh, as lecturer in geology, and there he remained until 1952, when he was appointed senior lecturer under Prof. C. E. Marshall at the University of Sydney. He was an outstanding success as teacher and lecturer, clear and vigorous in style and able to inspire in his students the enthusiasm which he brought to all his interests. During his Edinburgh days he joined the Territorial Army as captain in the Military Geology Group (Royal Engineers) and attended manoeuvres in Germany and elsewhere.

Rutledge's main research work was concerned with the structure and petrology of part of the plutonic complex of Loch Doon (Galloway) and its metamorphic aureole. His active interest in this area began while he was still an undergraduate; but it was not until he returned to university life that his wish to study it in detail was fulfilled. The first

Prof. Marston T. Bogert

By the death of Marston Taylor Bogert at the ripe old age of eighty-six, American and international chemistry has lost one of its most charming and effective personalities. Bogert was educated at Columbia University, where later he became professor and finally professor emeritus of organic chemistry. His main chemical interests lay in the synthesis of heterocyclic compounds such as the quinazolines and thiazoles. He also conducted many investigations on the preparation of derivatives of such aromatic compounds as pyrogallol, thiophene, terephthalic acid, phenacetin and cinnamic aldehyde. He was interested in pharmaceuticals and perfumes, and among the four hundred papers in his name one finds such interesting topics as the relationship between odour and molecular structure.

Bogert was president of the American Chemical Society during 1907-8, and it was during this period that he, together with O. L. Parsons, then secretary of that Society, succeeded in forming the first divisions within the American Chemical Society—a far-sighted political act which in these latter years has undoubtedly greatly assisted in maintaining the cohesion in that vast organization. During the First World War, Bogert was invited to Washington to organize and serve as first chairman of the Chemistry Committee of the National Research Council. He was elected president of the Society of Chemical Industry for the year 1912, and in the years 1918-19 he served as colonel in the U.S. Chemical Warfare Service. After the Second World War, Bogert devoted much of his time and energy to the resuscitation of the International Union of Chemistry, and he was, in fact, the first American citizen to be elected president of that body.

Although somewhat feeble physically and attended by a nurse, Bogert went through the lengthy and trying public functions which attended the seventy-fifth anniversary meeting of the American Chemical Society in New York in 1951. As a public speaker or toastmaster, he displayed a mind capable of much wit and charm, and at scientific dinners the wise always attempted to get a seat near the man with the mauve tie, a sign that Bogert had attended the New York dinner in honour of Sir William Perkin. His loss will be felt by his many friends on both sides of the Atlantic.

ERIC K. RIDGAL

NEWS and VIEWS

Royal Society: New Foreign Members

THE following have been elected foreign members of the Royal Society: Karl von Frisch (Munich), distinguished for his work on the physiology of the chemical and visual sense organs of animals, especially insects and fish; Otto Loewi (New York), distinguished as being the first to demonstrate the transmission of the effects of nerve impulses by the release of chemical transmitters; Karl Manne Georg Siegbahn (Stockholm), distinguished for his work on the accurate measurement of X-ray wave-lengths, both by crystal and diffraction-grating methods; Otto Struve (Berkeley, California), distinguished for contributions to observational astrophysics, particularly of double stars.

Electrical Engineering in the University of Wales:

Prof. Emrys Williams

PROF. EMBYS WILLIAMS, of the University College of North Wales, Bangor, has accepted the new chair of electrical engineering at University College, Cardiff, from October 1. Prof. Williams is a native of Liverpool and studied at the Liverpool Institute and the University of Liverpool, where he was awarded the Ph.D. degree for research on electro-acoustics. During 1934-37 he was a member of the scientific staff of the Research Laboratories of the General Electric Company, and was engaged on electro-acoustics, television and carrier telephony. For the following ten years he was lecturer in electrical engineering in King's College, Newcastle upon Tyne (University of Durham), being responsible for the light-current work of the department under Prof. J. C. Prescott. During this time he was associated with Messrs. A. Reyrolle and Co., switchgear manufacturers, Hebburn-on-Tyne, and was chairman of the North-eastern Radio and Measurements Group of the Institution of Electrical Engineers. He is the author of a well-known text-book on valve circuits. Prof. Williams has held the chair of electrical engineering at Bangor since 1947. Although founded largely as a result of a bequest earmarked for hydro-electricity and kindred subjects, the Department of Electrical Engineering at Bangor has in recent years been interesting itself more and more in the light-current branch of the subject. The departure of Prof. Williams coincides with the decision to specialize in this branch, sometimes loosely termed electronics, and a chair of 'applied electricity', within the Department of Physics, is to replace the chair of electrical engineering at Bangor.

Engineering in the University of Wales will thus in future be concentrated at the Cardiff and Swansea Colleges. The new course in applied electricity at Bangor will cover the rapidly growing developments in those parts of light-current electricity which occupy an intermediate position between physics and electrical engineering. Prof. Williams's move to Cardiff will be much regretted by his Bangor colleagues, where his good fellowship and capacity for clear thinking will be greatly missed. His future colleagues at Cardiff welcome him most warmly to his new field of activity, where he may be expected to play a prominent part in the development of education and research into the applied sciences.

Royal Aeronautical Society: Awards

THE following awards have been made by the Royal Aeronautical Society: *Honorary Fellowship Diplomas*, to Sir A. H. Roy Fedden and Sir Frank Whittle; *Society's Gold Medal*, which is the highest honour that the Society can confer, to Sir Geoffrey Taylor, for his outstanding contributions to aeronautical science; *Society's Silver Medal*, to Prof. W. J. Duncan, for his outstanding work in aeronautical science and education; *Society's Bronze Medal*, to Mr. H. B. Howard, for his long and valuable work on aircraft structures; *British Gold Medal*, to Mr. A. G. Elliott, for his outstanding practical achievement in the design and development of aircraft engines; *British Silver Medal*, to Mr. R. Brie, for his practical contributions to the development of rotary-wing aircraft; *George Taylor (of Australia) Gold Medal*, to Mr. V. A. M. Hunt, for his paper on air-traffic control to-day and to-morrow; and *Simms Gold Medal*, to Mr. E. D. Keen, for his paper on integral construction—its application to aircraft design and its effect on production methods.

Iron and Steel Institute: Awards

THE following awards have been made by the Iron and Steel Institute: *Bessemer Gold Medal* for 1954, to Dr. T. P. Colclough, technical adviser to the British Iron and Steel Federation, in recognition of his distinguished contribution to the development, in theory and practice, of the manufacture of iron and steel; *Sir Robert Hadfield Medal* for 1954, to Dr. A. H. Leckie, technical officer to the Iron and Steel Board and until recently with the British Iron and Steel Research Association, in recognition of his valuable contributions to research in steelmaking; *Andrew Carnegie Silver Medal* for 1953, to G. R. Bish, of Enfield Cables, Ltd., and formerly of University College, Swansea, for his report (written in conjunction with Prof. H. O'Neill, who was not eligible) on the deformation of austenite in relation to the hardness characteristics of steel (*J. Iron and Steel Inst.*, 173, 398; 1953); *Williams Prizes* for 1953 (two of £100 each), to A. H. Norris, of John Lysaght, Ltd., Scunthorpe, for his paper on soaking pit practice at the Normanby Park steelworks of John Lysaght, Ltd. (*J. Iron and Steel Inst.*, 173, 353; 1953), and to E. R. S. Watkin, of the Appleby-Frodingham Steel Co., for his paper on railway traffic of the Appleby-Frodingham steelworks (*J. Iron and Steel Inst.*, 173, 1; 1953); *Ablett Prize* for 1953, to F. Starkey, of Buckley and Taylor, Ltd., Oldham, for his paper on guides and strippers for modern rod and bar mills (to be published later).

Heavy-Water Atomic Reactor for Harwell

WORK is beginning on a new atomic reactor at the Atomic Energy Research Establishment, Harwell. This will be the fourth pile to be built at the Establishment and the first in Great Britain using heavy water as a moderator. For the past six years Harwell has had available two piles, BEPO and GLEEP. They have been used for research, and in particular for work in connexion with the design of the piles producing plutonium now in operation at Windscale and the newer nuclear energy electricity generating station now under construction at Calder Hall. However, the more advanced types of power pile now under consideration are likely to operate at a much higher intensity, and this should lead eventually to a reduction of capital costs and lower overall costs of

reactor operation. Accordingly, it has been decided to build at Harwell, in addition to the zero energy fast fission reactor (which has now been operating for some two months), a small research reactor operating at a very high intensity to permit the necessary experimental studies to be carried out. The new pile will also make it possible to produce certain radioactive isotopes such as cobalt-60, which cannot be made with sufficient specific activity in BEPO. The use of heavy water as a moderator enables the required facilities to be obtained at a lower capital cost than would be possible with a graphite-moderated system. The reactor will use as fuel highly enriched uranium which will be supplied from the diffusion plant operated by the Atomic Energy Industrial Group at Capenhurst. General design of the new pile is being undertaken by the Atomic Energy Research Establishment, while detailed design and provision of reactor components will be a responsibility of Messrs. Head Wrightson Processes. The Ministry of Works is undertaking civil and general mechanical work in connexion with site services, building and installation.

The Organization of Pure and Applied Science

THE address on pure and applied science and their appropriate forms of organization, which Prof. M. Polanyi delivered last July in Hamburg at the Congress on Science and Freedom (see *Nature*, 172, 445; 1953), has now been published as Occasional Pamphlet No. 14 by the Society for Freedom in Science (pp. 13, 1953; 1s. 3d.; from the Society at the Department of Zoology, University of Oxford). Empirical science, he points out, is based on observations, while technology is a collection of inventions. Not all empirical knowledge forms part of science, and only a part of technology is applied science. While empirical technology is necessarily unsystematic, it can be an important source of information worthy of scientific study. Such technically justified science, like systematic technology, founded on an application of science, forms a field of study lying between pure science and pure technology. The principles for the proper organization of research in pure science are determined by the distinctive characteristics of pure science; and since all real scientific discovery must show originality, expanding the system of science in an unexpected way, scientific discovery is an essentially independent task. Scientific research nevertheless must rely for financial support on public subsidies, and for the effective advancement of science as a whole the individual independent research tasks must be co-ordinated through a spontaneous system operating under the control of scientific opinion. Within this framework the function of the public authorities is to supply the scientist whose work is appreciated by public opinion with the means for pursuing his own interests in science, giving preference to those who have the greater prestige in science. The study of technologically justified branches of science should be cultivated under the auspices, and at the expense, of special interests served by the inquiry, but without drawing away too much talent from the pursuit of scientific inquiries of universal interest. The study of systematic technology should be organized like the advancement of pure science. Finally, Prof. Polanyi urges that, when the State establishes institutions for the cultivation of science, it recognizes a realm of independent ideas and independent men. It admits that the requirements of this realm demand con-

sideration equally with the political and material interests of the society guarded by the State, and by implication the State is committed to foster the advancement of science under the guidance of its own accepted scientific leaders.

Corrosion Prevention and Control

THE appearance in March of the first number of a new journal, *Corrosion Prevention and Control: Engineering—Equipment—Technology* (1, No. 1, March 1954; published from Holland House, 140 Cromwell Road, London, S.W.7; 30s. or 5 dollars for one year, and 75s. or 12.50 dollars for three years), is in line with the increasing interest being shown in the subject of corrosion prevention. This interest has already found expression in the formation in 1951, by the Society of Chemical Industry, of a Corrosion Group to encourage the presentation and publication of original papers and of reviews. The new journal is, however, the first in Britain to be devoted exclusively to the subject of corrosion, the aim being to present accounts of new developments in a form suitable for rapid appraisal by engineers, chemists and metallurgists who are concerned with the practical application of corrosion knowledge. In the first number this object has certainly been achieved. The editorial comment is of a high standard. Articles refer to cathodic protection, zinc anodes, metal pre-treatment, protection by paints and resistant plastics. Under the heading "Technical Review" are listed forty-one items relating to progress in corrosion prevention, while abstracts of twenty-three corrosion patents are given in a separate section. With two exceptions, all the articles are anonymous. The sixty-four pages in the first number include ten and a half pages of advertisements. It would be preferable, however, to paginate all advertisement matter separately. The publication of future issues of the new journal will be awaited with interest.

Collected Reprints of the National Institute of Oceanography

THE National Institute of Oceanography in Great Britain, following the example of the oceanographic institutions of the United States, has issued the first volume of the "Collected Reprints" of many of the publications of its staff (pp. vii + 61, December 1953; from the Institute, Wormley, Godalming, Surrey). The papers in question were originally published during the years 1949–53 inclusive, and are on many branches of both physical and biological oceanography, including the design and operation of instruments of observation. In accordance with the deliberate policy of the Institute, these papers appeared in a wide range of journals, few of which are of a specialized oceanographic character and some of which cater for the general reader. The alternative would have been for the Institute to publish its own journal, and indeed it does continue to publish the "Discovery Reports", which deal with work based mainly on the observations and collections of the former Discovery Committee, or closely related to that work. But the method of publication chosen for the newer work brings this to the notice of readers outside the field of oceanography, and gives the staff of the Institute the benefit of criticism from those using similar techniques. For oceanography is only the application of the various basic sciences to the acquisition of knowledge of the oceans. Of the papers written for the general reader, a good pro-

portion are by the director of the Institute, Dr. G. E. R. Deacon, and these serve an excellent purpose in popularizing the subject. It is very unlikely that anyone interested in the work of the Institute would have easy access to the majority of the journals used by the staff, and so the issue of collected reprints is specially welcome.

Oundle School Natural History Society

THE annual report for 1953 of the Oundle School Natural History Society, edited by B. W. H. Coulson and I. F. Thomas, has recently been published. It is disappointing to read that "Too much is still left to a few keen members and . . . how few members help by providing records". This remark does not necessarily indicate a lack of interest in practical natural history, for all too often the most enthusiastic fail to record their work, which is a pity from several points of view. Three lectures, a series of short talks and a conversation were some of the indoor activities of the Society during the year, and Oundle School took part in the annual exhibition of the Association of School Natural History Societies at the British Museum (Natural History) on November 7. Among the reports of groups are: mammals, in which a study of bats in Oundle is suggested; birds, recording rarities, phenology and ringing; fish—all coarse, freshwater species; Crustacea; Arachnida; Lepidoptera; Ephemeroptera; Hemiptera; Diptera; Annelida, including physiological experiments on leeches; flowering plants, including phenology, new species and ecology; fungi. Notes are also included in the report on the biology of a lake and a fen together with records of various animals kept in the laboratory. Oundle School is clearly taking advantage of its excellent position for field natural history, and is not lacking in enthusiasm. It is to be hoped, therefore, that the members of its Natural History Society will heed the remarks of the editors of the annual report concerning lack of written records, for this is very important.

Flora of the Belgian Congo

THE fourth volume of the "Flore du Congo Belge et du Ruanda-Urundi" (Publ. Inst. Nat. pour l'Étude Agron. du Congo Belge, pp. 314, with map and line drawings; Brussels, 1953) deals with the Spermatophytes, Papilionaceae (Part I), of this rich and varied floristic region. Accounts of the tribes Sophoreae, Genisteae, Trifolieae and Lotaeae, each contributed by a different author, are here given; the other tribes of this order will be dealt with in two subsequent volumes. Analytical keys are provided for the tribes, genera and species; the genera and species being described in detail (in French) with notes on their distribution and habitat and occasional illustrations. The publishers are to be congratulated on the clarity of the arrangement and text.

Arid Zone Research

THE general conference of Unesco at its sixth session held in Paris in 1951 authorized the Director-General "to collect and disseminate information on research being carried out on problems of the Arid Zone and on the organizations, scientists and engineers engaged in such research". As a result, the secretariat undertook a survey among the member States of the institutions primarily devoted to scientific and technical research on problems of arid and semi-arid areas. A directory has now been published which gives detailed information about

these institutions. The ninety institutions listed are located in sixteen countries and seven dependent territories spread over the five continents of the world. Copies of the directory can be obtained from H.M.S.O., price 8s. 6d.

British Institution of Radio Engineers: Convention in Oxford

THE third post-war convention of the British Institution of Radio Engineers will be on industrial electronics and will be held in the University of Oxford during July 8-12. The Institution's Clerk Maxwell Memorial Lecture will be delivered in the Clarendon Laboratory, Oxford, by Sir John Cockcroft, director of research, Atomic Energy Research Establishment, Harwell, on the evening of July 8. More than thirty papers will be presented at the six sessions, which will be as follows: industrial applications of electronic computers; industrial applications of X-rays and sonics; nucleonic instrumentation and application; electronic sensing devices (transducers); process control; and industrial aids to production. The registration fee for members of the Institution is 10s. 6d. a day or £1 11s. 6d. for the whole convention (for non-members, £1 1s. and £3 3s., respectively). Accommodation may be reserved at Christ Church, Oxford. A detailed programme and reservation forms can be obtained from the Secretary of the Institution, 9 Bedford Square, London, W.C.1.

South-Eastern Union of Scientific Societies: Congress in Maidstone

THE fifty-ninth annual congress of the South-Eastern Union of Scientific Societies will be held in the Museum and Art Gallery, St. Faith Street, Maidstone, during June 10-13. After his induction on June 11, the new president of the Union, Dr. Glyn Daniel, will give an address on "The Art of Megalith Builders". The Union is divided into archaeology, botany, geology and zoology sections, and the individual presidents of the sections and the titles of their addresses will be as follows: *Archaeology*, F. C. Elliston Erwood, on the present state of monastic archaeology in Kent; *Botany*, J. E. Lousley, on the amateur botanist in 1954; *Geology*, H. E. P. Spencer, on the Pleistocene period and work for the amateur geologist; *Zoology*, Dr. G. E. Newell, on animal zones of the North Kent coast. Further information can be obtained from the honorary local secretary for the meeting, L. R. A. Grove, Museum and Art Gallery, St. Faith Street, Maidstone.

Physical Society: Summer Meeting

THE annual summer meeting of the Physical Society will take the form this year of three open lectures (no ticket of admission being necessary), given in connexion with the General Assembly of the International Union of Pure and Applied Physics, and will be held at the Royal Institution, 21 Albemarle Street, London, W.1, on July 7 and 9 at 4.30 p.m. and on July 13 at 2.30 p.m. The lectures will be as follows: fields and particles, by Prof. J. A. Wheeler (Palmer Physical Laboratory, Princeton University); the European Organization for Nuclear Research, by Prof. E. Amaldi (Guglielmo Marconi Institute of Physics, Rome); and microwave experiments in the physics of solids, by Prof. C. Kittel (University of California, Berkeley).

Easterfield Medal of the New Zealand Section, Royal Institute of Chemistry

THE New Zealand Section of the Royal Institute of Chemistry has instituted a new silver medal, to be known as the Easterfield Medal, in honour of the late Sir Thomas Easterfield, the first professor of chemistry in Victoria University College, Wellington, and later the first director of the Cawthron Institute. The Medal will be awarded every two years to a New Zealand chemist less than thirty-five years of age who has carried out research work of outstanding quality and originality, the major portion of it being done in New Zealand. The first award will be made this year, and further details can be obtained from the honorary secretary, New Zealand Section, Royal Institute of Chemistry, P.O. Box 250, Wellington, C.I.

Royal Institution: Officers

At the annual meeting of the members of the Royal Institution, held on May 1, the following officers were elected: *President*, Lord Brabazon of Tara; *Treasurer*, Dr. L. H. Lampitt; *Secretary*, Mr. S. Robson; *Managers*, Mr. E. R. Davies, Sir Walter Drummond, Sir Alfred Egerton, Mr. H. S. Gibson, Mr. A. C. Hartley, Mrs. H. K. Hawkes, Prof. A. V. Hill, Mr. L. B. W. Jolley, Dr. H. Lowery, Mr. A. J. Philpot, Mr. W. E. Schall, Mr. P. H. Schwarzschild, Sir George Thomson and Mr. Frank Wakeham; *Visitors*, Mr. W. W. Abson, Mr. F. G. Brown, Dr. H. K. Cameron, Mr. A. D. R. Caroe, Mr. A. H. Ewen, Prof. James Greig, Wing Commander G. e. Hughes, Dr. G. M. Lees, Prof. Kathleen Lonsdale, Mr. Arthur Marshall, Mr. M. M. Melnsky, the Hon. Philip Samuel, Dr. P. C. Spensley, Mr. W. R. Stevens and Dr. Norman Stuart.

Royal Photographic Society Exhibition of Under-water Photography

AN exhibition of photographs taken under water has been arranged by the Royal Photographic Society and will be on show in its house at 16 Princes Gate, London, S.W.7, until May 29 (Sundays excepted), admission free. It comprises about a hundred photographs, in monochrome and colour, of subjects by Commandant Jacques-Yves Cousteau, Henri Broussard, Dimitri Ribikoff, and Robot-Berning and Co., and members of the Under-water Explorers Club. Other items include photographs from Marconi's Wireless Telegraph Co., Ltd., and Siebe Gorman and Co., Ltd., taken off the monitor screen during under-water television operations. The Royal Naval Scientific Service has contributed a special section of fifty prints, showing propeller studies, wreck surveys and experimental techniques.

Earthquakes during February

THERE were some twenty-six strong earthquakes during February, twelve of which had instrumental magnitude 6 and greater. The greatest two had instrumental magnitude $7\frac{1}{2}$ and occurred on February 1 near the Volcano Islands (lat. $24\frac{1}{2}^{\circ}$ N., long. $142\frac{1}{2}^{\circ}$ E.) and on February 11 in Ningxia Province, China (lat. $39\frac{1}{2}^{\circ}$ N., long. 101° E.), respectively. The shock which did most damage during the month had instrumental magnitude $6\frac{1}{2}$ and an epicentre near lat. $17\frac{1}{2}^{\circ}$ N., $92\frac{1}{2}^{\circ}$ W., causing extensive property damage at Chiapas in Mexico. Two earthquakes occurred at a focal depth of 600 km., the first being on February 14 near the Fiji Islands, and the second on February 20 in the Flores Sea. Reports were received from the

United States Coast and Geodetic Survey in co-operation with Science Service and the Jesuit Seismological Association, Durham, Lwiro (Belgian Congo), Pasadena, Strasbourg, Toledo and Uccle.

Announcements

WE regret to announce the death on April 25 of Lady Mary Lilian Boyd Dawkins, widow of Sir William Boyd Dawkins, aged ninety.

THE Council of the Royal Society of Edinburgh has awarded the Keith Prize for the period 1951-53 to Dr. D. E. Rutherford, Department of Mathematics, University of St. Andrews, for his paper, "Some Continuant Determinants arising in Physics and Chemistry", and other publications in the *Proceedings* of the Society.

THE first Dickinson Memorial Lecture of the Newcomen Society will be delivered by Prof. Charles Singer in the Science Museum, London, S.W.7, on May 12 at 6 p.m. The Lecture is to be a biennial one.

At the annual meeting of the Zoological Society of London on April 29, Sir Landsborough Thomson was elected president in succession to Lord Alanbrooke. Dr. T. C. S. Morrison-Scott was elected treasurer, and Lord Chaplin secretary. New members of Council are Captain K. Caldwell, Mr. A. Ezra, Lord Forester, Dr. H. W. Parker, Mr. Peter Scott and Mr. S. Wilson Kitchen.

MR. J. E. CUMMINS, chief scientific liaison officer, Australian Scientific Liaison Office, London, is returning to Australia after six years in London. He will be succeeded by Mr. Walter Ives, who is at present secretary (agricultural and biological sciences) of the Commonwealth Scientific and Industrial Research Organization, Melbourne.

THE Minister of Transport, the Right Hon. Alan Lennox Boyd, will open the new research laboratory and proving ground of the Motor Industry Research Association at Lindley, near Nuneaton, Warwickshire, on May 21.

AN exhibition on "Dry Rot and Woodworm" will be opened at the Royal Sanitary Institute (90 Buckingham Palace Road, London, S.W.1) on May 12 by the Right Hon. Sir David Eccles, Minister of Works. The exhibition is being presented in collaboration with the Department of Scientific and Industrial Research and the Central Office of Information, and will remain open until July 17.

THE British Society of Rheology is holding a conference on "Rheology in Mechanical Engineering" in the Mechanical Engineering Research Laboratories, East Kilbride, near Glasgow, during June 10-12. The conference will be free and open to anyone interested in this field. Application forms, to be returned before May 15, can be obtained from Dr. D. P. Feltham, Flat H.12, Sloane Avenue Mansions, London, S.W.3.

THE Committee on Vacuum Techniques is holding a symposium during June 16-18 at the Berkeley-Carteret Hotel, Asbury Park, New Jersey. About twenty-five papers will be read, discussing nomenclature and standards; new equipment and instruments; fundamental developments in vacuum technology; methods and techniques; applications; and processes. Persons and organizations interested in attending the symposium should write to the Committee on Vacuum Techniques, Box 1282, Boston 9, Mass.

MYXOMATOSIS IN RABBITS IN GREAT BRITAIN

THE Advisory Committee on Myxomatosis in Rabbits, appointed in 1953 by the Minister of Agriculture and Fisheries and the Secretary of State for Scotland, has now issued a report* which describes the history and nature of this disease, its present distribution in Great Britain, the protection of domesticated rabbits from it, the harm done by rabbits to agriculture and the present recommendations of the Committee with regard to the disease. Myxomatosis was first reported in 1898 from Montevideo. It is a disease caused by a virus which, so far as we know at present, affects rabbits only. Man, domesticated and other animals cannot be infected with it. It is transmitted purely mechanically to rabbits by the fleas, lice, mosquitoes and mites that suck the blood of the rabbit, and these blood-sucking arthropods act just as a pin infected with the virus might. An infected pin may remain capable of transmitting the virus for twelve days, and the mouthparts of a blood-sucking arthropod may remain infective for twenty-five days. The disease has been used successfully in France and Australia for killing large numbers of rabbits, and the benefit to agriculture is already evident. Recently, the disease has spread to Luxembourg, Belgium, Germany, the Netherlands and Spain. During 1936-38 attempts were made to establish the disease among the rabbits on Skokholm Island, off the Pembrokeshire coast, but these failed. In 1953 the disease broke out in Kent and East Sussex, its source being unknown. Attempts were then made to control its spread; but since then, further outbreaks have been confirmed, and at present six of these have been recorded from Kent, two from East Sussex, three from Essex and one from East Suffolk. The localities where these outbreaks have occurred are shown in a map published with the report.

During laboratory experiments on the disease and in natural outbreaks of it, more than 99 per cent of rabbits infected have died; but those that survive develop an immunity, and it is believed in Australia that rabbits there are becoming immune to the disease and that the very high mortality of rabbits that has occurred in that country is now falling considerably. The development of immunity may therefore prevent the use of the disease for killing rabbits in the future.

The report contains a valuable section on the economics of the wild rabbit. Representatives of the rabbit meat, fur, fur felt and fur felt hat trades have estimated that their trades deal each year with 40 million rabbits. The rabbit meat obtained is worth about £7 million and the skins about £8 million, £3½ million of the latter being represented by exports to the United States. Thus wild rabbits provide in Great Britain a total income of about £15 million a year.

Estimating the cost of the harm that wild rabbits do, the Committee states that nine rabbits eat about as much as two sheep, so that the estimated popula-

tion of Great Britain of about 60-100 million rabbits, which feed largely on agricultural crops and grass, can deprive domesticated animals of a great deal of food. It has been estimated that rabbits may cause losses of the order of 160,000 tons of wheat a year, which is worth £5.2 million, and damage to other cereals of the same order, so that the annual loss in this respect is of the order of £15 million. The most extensive damage is done to grassland, the cost of this being estimated at £21 million a year. Rabbits also damage kale, swedes and other vegetables and also fruit trees; the harm they do to young trees in forestry plantations makes it necessary to protect these trees at an annual cost of about £2 million. The Committee considers, in fact, that the damage done by wild rabbits in Britain costs three or four times the income they bring to the trades dealing in them. In Australia it was estimated that the destruction of rabbits resulted in an increase of rural production worth £50 million during 1952-53 alone.

In order to reach its conclusions the Committee consulted representatives of the animal welfare societies, agriculture, forestry, the trades dealing in rabbits and those concerned with the domestic rabbit. The chairman of the Royal Society for the Prevention of Cruelty to Animals and the chairman of the Committee on Cruelty to Wild Animals are members of the Committee. The animal welfare societies supported the organization of a national campaign to exterminate the wild rabbit by every humane method available as a means of preventing future suffering. The representatives of agriculture and forestry, with the exception of the National Farmers' Union of Scotland, were not generally in favour of deliberate spread of myxomatosis; they felt that, until we know more about the disease, it should be allowed to spread naturally. The representatives of trades dealing in rabbits were concerned about the possible effects of the disease on their trades, and the producers of domestic rabbits sought protection for the domestic rabbit.

The Committee concluded that attempts to control the natural spread of the disease would serve no practical purpose, but that, for humanitarian, legal and other reasons, no attempt should be made to help the spread of the disease or to introduce it where it does not naturally occur. It recommends that the disease should be allowed to run its natural course and that, whenever outbreaks occur, attempts should be made to eliminate survivors of it before they are able to produce numerous offspring immune to the disease. The importation of such live rabbits as the cotton-tail rabbit, which might rapidly become a pest in Great Britain, should be prevented. Special protection should be given to domestic rabbits and information about the best methods of doing this should be distributed. The vaccine which is the only known preventative of the disease should be made available at a reasonable cost to rabbit breeders. The Committee is, meanwhile, watching the disease, and it has started research on it. Further advice will be issued as occasion arises.

NATIONAL COLLEGE OF HOROLOGY AND INSTRUMENT TECHNOLOGY

THE National College of Horology and Instrument Technology was founded in 1947 for the training of technicians in the horological and instrument industries. It is accommodated within the Northampton Polytechnic, London, E.C.1. Shortly after the Second World War the horological manufacturing industry was re-established, and in consequence there was a great need for engineers with a good knowledge of horological theory and of production methods applicable to fine mechanisms. The first course instituted at the College was a three-year diploma course in horology for students over the age of sixteen. The standard of this diploma is of the order of the first part of a degree in engineering, and the curriculum, in addition to covering academic subjects, includes a liberal allocation of time to workshop technology and practice.

During recent years the academic content of the curriculum of the diploma course has been modified somewhat to include instrument technology as well as purely horological work, the remainder of the theoretical and almost the whole of the practical work of the course being found to be admirably suited to the needs of the instrument, as well as the horological, industry. In fact, many students leaving the College obtained posts in the field of instrument design, development and manufacture, even before these modifications were adopted.

The College is equipped with a comprehensive range of general and specialized machine-tools and instruments suitable for almost any branch of fine-instrument and light-engineering production, and the variety of practical work given to students in this course is made as wide as possible. In addition to the specialized facilities in the National College itself, the full resources of the departments of the Polytechnic, including instrument engineering, mechanical and electrical engineering, applied physics, metallurgy and mathematics, are available for students at the College, these departments providing specialist lecturers in individual subjects.

Building extensions costing upwards of £350,000 are at present in hand at the Northampton Polytechnic, and the Instrument Engineering Department has acquired completely new workshops and laboratories. These extend its scope considerably and improve the facilities it is able to offer to the National College in connexion with advanced courses in instrument technology. Extensions to the premises of the National College are also planned which will more than double the space at present available. This space will be devoted to advanced workshops and laboratories for students in both horology and instrument technology.

To co-ordinate the diploma course in horology with training in industry, the British Clock and Watch Manufacturers' Association has sponsored a student-apprentice scheme which supplements the three years spent at the College with a further two years in the works of a member firm. Deferment from military service is normally granted for the full five years and, during the final two years, student-apprentices are expected to continue part-time for a Higher National Certificate. This enables them to qualify for graduateship of one of the engineering

institutions—mechanical, electrical or production—partial exemption being granted on gaining the College diploma.

Extension of Courses

Although many ex-students are employed on instrument engineering with member firms of the British Clock and Watch Manufacturers' Association, the governors of the College are anxious to extend its facilities to other branches of the instrument industry. To this end, discussions have recently been held with the Scientific Instrument Manufacturers' Association to ascertain the types of courses best suited to the industry. An open day was held at the College on March 16 to enable member firms of the Association and other interested persons to inspect the workshops and laboratories, and this attracted some sixty to seventy representatives, many of whom expressed surprise and pleasure at the high quality and variety of equipment.

The two main courses proposed have received wide support. The first proposal is to establish a diploma course in instrument technology having much in common with the present diploma course in horology; with the development of this course, it may well be that horology will take its place as a special branch of instrument technology.

The second proposal is for an advanced course, one year in duration, for postgraduate and post-Higher National Certificate students. At present the instrument industry recruits to its technical and executive grades graduates in physics and engineering. It is found necessary to give these men a period of training in the industry before they are fully competent, and it is suggested that the College could undertake a good deal of this training. The actual length of this course would be one session, eight months in duration.

The curriculum will include a certain number of basic subjects such as applied physics, instrument design, workshop technology, metrology and industrial administration, as well as a number of optional subjects such as advanced mathematics, instrument workshop practice and metallurgy, together with particular branches of instrument theory such as mechanical, electrical, electronic, optical, industrial control and servo-mechanisms. It is envisaged that students holding degrees or Higher National Certificates in physics may well require tuition and practical experience in engineering, production and management subjects, as well as a more detailed knowledge of the technology with which their firm is associated. Students who have taken general engineering will need further tuition in applied physics, production and instrument engineering, while those who have National Certificates in production engineering may wish to study applied physics and perhaps some basic engineering subjects.

National colleges are intended to serve and co-operate fully with their respective industries, and it is therefore essential that approved forms of student-apprenticeships and postgraduate scholarships should be established by the trade associations or the larger firms.

Production and Research

Finally, it should be noted that the interests and facilities of the College are by no means limited to formal instruction. A certain amount of specialized

manufacture is already undertaken where the work involved provides valuable experience for students, and the College is well equipped to accept suitably qualified students for research in various branches of design, development and production applicable to instruments, fine mechanisms, horology, automatic control and so on.

UNIVERSITY COLLEGE OF THE WEST INDIES

DEPARTMENT OF ZOOLOGY

By PROF. N. MILLOTT

THE West Indies have always formed a fruitful area for the prosecution of zoological research, and now, as in the past, excellent work is being done by the Institute of Jamaica and a well-established Natural History Society. In recent years the facilities for such studies have been increased by the establishment of a Department of Zoology in the new University College of the West Indies. Though facilities have been in existence from the inception of the College in 1948, it is only recently that they have been fully realized by the housing of the Department in permanent accommodation.

The Department is situated in the University grounds of some seven hundred acres and is readily accessible, being seven miles from Kingston. It is designed and organized for both teaching and research. As a teaching unit it is responsible for the training of undergraduates for degrees in science, and the intermediate and First M.B. examinations of the University of London, with which the College is privileged to maintain a special relationship. Provision has also been made for the training of post-graduate students for higher degrees.

The buildings were designed by the University College architects, Messrs. Norman and Dawbarn, of London, in conjunction with the head of the Department, and they were completed in October 1952.

Mostly on one level, the laboratories include a large elementary and a smaller advanced teaching laboratory, suitable for the study of systematic

zoology, animal morphology, histology, etc. In addition, there are an experimental laboratory for physiological studies, a small museum, an aquarium room, offices, a photographic dark room and a lecture room. Two research laboratories are provided. All the laboratories are fitted with the usual services, and in addition, both the experimental laboratory and the aquarium room have compressed-air mains. Very shortly a salt-water circulator will be installed in the aquarium room. The furnishings are executed in local woods and were designed and constructed on the University College site.

The laboratories have been equipped and staffed, so far as possible, for a comprehensive study of zoology, rather than for highly specialized studies of particular aspects. In this way it is hoped that the Department will not only be able to give its students an adequate training in the ever-widening sphere of zoology, but will also provide a type of research centre that has long been required in the central Caribbean.

From the first the Department has aimed at encouraging visiting research workers to use its laboratories and in this a real beginning has been made, the Department having already accommodated research workers under the Fulbright scheme and two members of the staff of the University of Glasgow. It is hoped that other institutions and organizations will encourage investigators to use the facilities now available.

Since the beginning, members of the teaching staff of the Department have been actively engaged in research, and the existing programme falls into six main divisions. A study of the Collembola of Jamaican soils is being undertaken, which, initially, will involve the determination of species, and later, studies of population density and distribution. The Nuffield Foundation has generously offered financial assistance for this study. A second division consists of evolutionary studies on snakes and lizards. These have involved investigations of the details of speciation in Jamaican reptiles, comparative anatomical studies including a special study of the retina, and distributional studies which bear on the evolution of higher taxonomic categories and the problem of the origin of snakes. Researches on the thymus of

Zoology Laboratories, University College of the West Indies

reptiles and mammals, particularly primitive forms such as the sloth, are being pursued, and studies are also being made of the anatomy of the rare, beaked whale *Mesoplodon*, two individuals of which were recently washed up on nearby shores. Hitherto undiscovered platytenid ctenophores have raised interesting problems in connexion with their phylogeny and distribution, which are now being tackled in the Department. Lastly, a study of local echinoids has revealed in certain forms a striking sensitivity to light. Since they lack morphologically defined photoreceptors, their mechanism of perception is clearly of great interest and it is being analysed in detail in one species. Rather unexpectedly, the study has yielded interesting results in relation to melanogenesis in this form, and the research has recently received the support of the Rockefeller Foundation.

Visiting workers have undertaken research on the taxonomy and distribution of Jamaican frogs, the effect of thyroid inhibitors on the development, and that of phenylthiourea on the pigmentation, of *Eleutherodactylus*. The bionomics of black widow spiders and scorpions, and the feeding processes of bivalve molluscs, have also been investigated.

The geographical location of the Department is admirable for zoological studies, since the surrounding collecting grounds are readily accessible by good roads. Seaward, some ten miles distant, lies Kingston Harbour with fertile collecting grounds afforded by cays, lagoons, mangrove swamps and innumerable bays and inlets. The north coast of the island with its accessible coral reefs is some thirty miles away, and nearby salt ponds, periodically land-locked, offer a worthy opportunity for ecological studies. Landward, there are areas showing diverse climatic, topographical and geological conditions. From dry plains, mountains clothed in forest rise in succession to 7,000 ft., and most areas are accessible by road.

In general, these areas yield an abundance of animal forms for systematic, ecological and physiological studies. Echinoderms, molluscs and many insects occur in spectacular quantity. The embryologist will find much of interest in the abundant eggs of lizards, geckos and anurans with direct development. For those interested in migration problems, it is appropriate to note that the island is visited not only by migrant birds but also by migrant butterflies.

In the past it was necessary for many visiting research workers to limit their activities largely to collecting and preserving. Such drastic limitations are fortunately no longer necessary, and with the facilities of modern, well-equipped laboratories at their disposal, they may now undertake experimental work no less readily than microanatomical or cytological studies, for the Department is equipped with a comprehensive range of research microscopes, rocking, rotary, sliding and freezing microtomes, kymographs, thermostatic baths, Warburg apparatus, centrifuges, pH meters and a Beckman spectrophotometer.

Finally, it might be mentioned that library facilities are available, not only in the University College, which maintains a first-class library with a microfilm service, but also in the nearby library of the Institute of Jamaica, the staff of which render invaluable assistance to visiting research workers. It is hoped that with these added facilities many zoologists who hitherto have demurred will seize the opportunity of extending the horizon of their animal studies and make use of the facilities that are now available in this supremely fascinating part of the earth.

ATOMIC ENERGY AND MORAL ISSUES*

OWING to the controversial nature of the subject of the moral issues involved in the utilization of atomic energy, two speakers, Prof. Kathleen Lonsdale and Sir George Thomson, were asked to express their views. Their respective methods of approach to the subject, which to a large extent centred around the morality of war, may be summarized in Prof. Lonsdale's words: "I believe that all war is wrong, with whatever weapons, because it is made up of hatred, falsehood and savagery; and because it perpetuates these things. . . . But even if these fundamental objections to war as such are set on one side, I still see in an atomic war, or indeed in any other form of future world war based on scientific super-weapons, a menace to every kind of decency towards one another as human beings that we have painfully achieved throughout the ages. Men die horribly every day; buildings decay and become ruins. What is more horrible is that we ourselves, whether as a means of offence or of retaliation for aggression, should deliberately let loose hell on earth; and that is what atomic warfare would be, no matter how much we may deceive ourselves into supposing that we can ameliorate it with the deep shelters, protective clothing and Geiger counters of civil defence". And in Sir George Thomson's words: "Two societies, or the same society at different times, may with perfect honesty have different codes and judge differently what is right in different circumstances. This is, partly at any rate, the answer to the question of expediency. Right and wrong exist quite independently of expediency. But a code which does not consider expediency is a bad one and will not last. The consequences of acts do matter for moral judgments. It is permissible to indulge in the alkaloid contained in tea, but not in that contained in heroin simply because the long-term consequences are different".

Prof. Lonsdale rejected the doctrine of expediency and appealed to Christianity as a standard by which the rightness or wrongness of any course of action may be judged. "I know," she continued, ". . . it is not possible to prove that there are any absolute standards. Certainly none of us can claim that ours are the only true standards. We know, indeed, that our standards as scientists have at least different priorities from those of some other people. . . . Yet whatever our priorities we do know that there is for us and for all men a 'moral law within', however much we may ignore it or attempt to rationalize it away. Truth, generosity, brotherly love, justice, mercy, integrity are recognized as good, and the Golden Rule 'As ye would that men should do to you, do ye even so to them' still has a compelling force for us which is its own authority. . . . Very often the choice that confronts us in issues relating to Atomic Energy is one between a certain wrong to other people and a possible injury to us or to our nation. When this is so then I submit that it is morally wrong to put a possible or probable wrong to ourselves, or even to those we love, before an absolutely certain injury to others.

* Summary of lectures by Prof. Kathleen Lonsdale, F.R.S., and Sir George Thomson, F.R.S., being the sixth of a series of public lectures arranged by the Atomic Scientists' Association and the Department of Extra-Mural Studies, University of London (see also *Nature*, February 27, p. 336; March 13, p. 477; March 27, p. 573; April 3, p. 621; and April 10, p. 668).

"I believe that this is relevant in our discussion of whether we should build up stockpiles of atomic weapons, even as a means of preserving peace. I want peace to be preserved, not simply because human beings would die horribly in war in which atomic weapons were used, but because in wartime ideals are the first casualties, and because I believe that our democratic ideals would not survive an atomic war. In many ways atomic weapons are intrinsically no different from other weapons—I cannot see that it is more terrible to die in the heat of an atomic blast than to die from the effects of 'napalm', or even from the accidental flare-up of a nylon garment."

Against this point of view, Sir George stated: "I assume, in common with the great majority of Christians of all ages, that though war is an evil there are occasions on which it is the duty of governments to declare it and of their citizens to help to wage it. After all, if one does not assume this there is no specific problem, one would hardly suppose that atomic bombs are right if swords are wicked. The main question is 'what limitations if any should a country place on the methods it is prepared to use in a war it believes just', with as a secondary one 'are these limitations absolute or do they depend at all on what the enemy does?'"

"It seems to me that since the object of fighting is, or should be, to bring about a just peace, a method of war is good in proportion as it is effective and bad in proportion as it causes suffering and economic loss. Its merit is a sort of ratio of the two. Notice, method of war, not weapon. The rifle is perhaps as humane a weapon as man has invented, but if it is used to massacre a defeated population that method of war is a very bad one."

In discussing whether a stockpile of atomic bombs will minimize the possibility of another war, he said: "... the presence of a lot of atomic bombs in the world very substantially reduces the chances of a big war. The United States is very bomb-conscious, and the mere fact that Russia did not force matters in Europe when she was so strong is evidence of her fear. ... There is, I believe, a genuine fear of all-out war and a feeling that in a major war there will be no gallery seats. Even the horrors of the hydrogen-bomb, for which there is no moral defence as a weapon ... , are helping to the cause of peace. I believe attempts at disarmament are futile and that the bitterness and back-biting which abortive disarmament conferences inevitably cause are a real danger to peace".

ACTA HYDROPHYSICA

A NEW JOURNAL OF MARINE PHYSICS

THE first three issues of the new journal, *Acta Hydrophysica**, sponsored by the Institute for Physical Hydrography of the German Academy of Sciences, Berlin, have recently been published and distributed to various addresses on exchange terms though without any indication as to the price at which this well-produced journal can be bought. The three numbers have 139 pages in all (21 cm. x 15 cm. in size), and it is announced by the publishers (Akademie-Verlag, Berlin) that its appearance will be irregular. The journal is edited jointly by Dr. H.

* Deutsche Akademie der Wissenschaften zu Berlin. Institut für Physikalische Hydrographie. *Acta Hydrophysica*, Band 1, Heft 1, 1953. Pp. 56. (Berlin: Akademie-Verlag, 1953.)

Ertel, director of the Institute of Physical Hydrography at the Humboldt University in Berlin, and by Dr. J. Fischer.

If, as may safely be surmised, the purpose of the Institute of Hydrography is to launch a journal devoted exclusively to what would be known in Britain and the United States as 'physical oceanography', then its new publication stands as the first to be confined to that limited but very important field. Because of the inevitable and ever-growing attention to problems within the field of marine physics, a real need has been felt in Britain for a specialist journal in which papers dealing with ocean physics and related meteorology could be published, and good wishes will accordingly be extended to the new German venture.

In an opening paper by H. P. Schmitz on the processes associated with the cooling of inland lakes, it is asserted that relationships hitherto used in connexion with turbulent heat conduction in water are assailable on the grounds that they took no account of the dependence of the water density upon temperature. Though, under frequently occurring conditions, the same equation for turbulent heat conduction is obtained as that arrived at by Wilh. Schmidt, more complicated conditions usually arise—particularly around the temperature of maximum density and through warming. The treatment by Schmitz is unidimensional only, and the conditions where such treatment is permissible are recounted. He deals with the cooling of a column of lake water from surface downwards in the presence of thermal convection and turbulent heat conduction, and derives a connexion between the depth reached by convection and the time of its attainment when surface temperature fluctuations, cooling-rates and the magnitude of the turbulent heat conduction are known. He studies two cases: when there is a night-produced discontinuity layer, and when there is a night-time decrease of vertical temperature gradient—both due to the joint effects of thermal convection and turbulent heat conduction. Finally, he deals with the cooling of a column of lake water the temperature of which lies between those of freezing and of maximum density, and derives a differential equation which serves for the solution whatever be the commencing and the marginal conditions.

An article by J. Fischer on a nomographical process in oceanography presents a new method of using projection paper to carry out certain computations by means of accepted processes of nomography, and applies it to two examples concerned with rainfall. Adrian Steleann writes on the problems posed in lake plankton studies by the degree to which physical factors exert influence and impose distribution limits. He concerns himself with light penetration and temperature gradients in the vertical, the influence of light having only biological significance, whereas temperature has both that and mechanical influence.

Sinking-speed is dealt with in the light of Ostwald's relationship of that quantity to body density, viscosity and body form, and, finally, a discussion is given around the various lake plankton forms characteristic of the four seasons. A 27-page paper by K. Vollbrecht deals with the axial arrangement of quartz grains in sandy sediments. By studying a definite selection of suitable grain sizes, the axial arrangement of quartz grains can (says Vollbrecht) show reliably what the conditions of currents must have been when the sediment was laid down, par-

ticularly as to direction. H. Griesseier and K. Vollbrecht report upon experiments carried out to throw light on the building of bars off river mouths. They discuss the effects due to the slackening of water speed as the cross-section increases, and those due to electrolytic dissociation in sea-water. They also discuss the dependency of bar-building upon the contact of river and sea waters. H. Griesseier writes on the reflexion of sunlight impinging directly upon an agitated water surface, and in the final article, by Joh. Fischer, there is a discussion of a nomographic method for evaluating trigonometrical functions.

J. N. CARRUTHERS

CARNEGIE UNITED KINGDOM TRUST

REPORT FOR 1953

THE fortieth annual report of the Carnegie United Kingdom Trust covers the year 1953*, the mid-year of a quinquennium, and records the opening of new premises for the Scottish Central Library at Fisher's Close, in the Lawnmarket of Edinburgh, on November 5 as the most important event of the year in the field of general educational services. The new building provides space both for the storage of books and for the proper accommodation of the library staff and has been planned with an eye to future expansion.

Out of reports on the employment and training of social workers, issued in 1947 and 1951, proposals have now emerged for the establishment of a one-year course of 'basic' training, designed to follow the acquisition of a general university qualification in social science and providing an alternative to more specialized courses of training now required by many bodies employing social workers. A provisional allocation of £20,000 has been made towards the cost of a four-year experiment. A grant of up to £30,000 has been offered to the governing body of Brentwood, the recuperative centre for mothers, with children, whose family life has gone wrong, maintained by the Community Council of Lancashire to enable extensions and improvements in the accommodation to be made. In October 1953, Dr. John Spencer took up his duties as a director of a social project in Bristol concerned with the establishment of practical means of tackling those stresses and strains which arise in a developing community in the form of delinquency and other disturbances. The project, which is designed to cover a period of five years, will place its main emphasis on encouraging local initiative and on getting local residents to accept more responsibility for their community life, and £25,000 has been allocated by the Trust for this project.

It has been necessary to abandon the residential clinic for difficult children, opened in November 1950; but the Trust has asked the Family Welfare Association to arrange for the preparation and publication, under the title "Family Casework and the Country Dweller", of an account of two experiments in rural casework in Oxfordshire and parts of Northumberland and Durham. A grant of £10,000 over five years on a diminishing scale has been promised to the National Association for Mental Health to establish and maintain a regional office in Leeds.

* Carnegie United Kingdom Trust. Fortieth Annual Report, 1953. Pp. viii+86. (Glasgow: Royal Technical College, 1954.)

ANALYSIS OF THE 1953 STORM SURGE IN THE NORTH SEA

AN analysis of the storm surge of the night of January 31–February 1, 1953, which caused the disastrous floods in eastern England and Holland, has been published by J. R. Roositer (*Phil. Trans. Roy. Soc., A*, 246, 371; 1954). Using tide-gauge data from thirty-three stations around the North Sea, he has eliminated the tidal rise and fall by the methods developed by A. T. Doodson and R. H. Corkan, and has constructed diagrams and charts showing the disturbance of sea-level at three-hourly intervals from 09.00 hr. on January 31 to 03.00 hr. on February 2. The meteorological conditions are shown by a similar series of charts, and from the two it is possible to follow the development of the surge.

The peak of the disturbance was greatest between East Anglia and the mouths of the Scheldt, where the water rose to between 9 and 11 ft. above the predicted levels, and in many places this occurred very near the time of high water. In the extreme south of the region the levels would, no doubt, have been even higher if some of the water had not been able to escape through the Strait of Dover into the English Channel. At the time of maximum disturbance, the mean level of the whole North Sea was raised by 2.2 ft., corresponding to the influx of 15 billion cu. ft. of water from the north. The effect of the earth's rotation was apparent in causing the incoming wave of the surge to be higher on the east coast of Britain, while the outgoing wave was higher on the continental side of the North Sea.

Mr. Roositer has applied the method devised by R. H. Corkan for predicting the surge at Southend, and found that the initial rise and first peak were predicted fairly accurately; but the subsequent course of the surge was about 2 ft. lower than predicted, owing possibly to insufficient allowance being made for the escape of water through the Strait of Dover. After reviewing previous attempts to predict storm surge effects, he suggests several possible improvements in the methods of prediction. The 1953 surge appears to have been caused directly by the northerly winds in and immediately to the north of the North Sea, and there is no evidence of any appreciable external surge component, coming in from the Atlantic, which was a feature of some previous surges.

VELOCITY DISTRIBUTION OF SPORADIC METEORS

IN a paper entitled "The Velocity Distribution of Sporadic Meteors, IV: Extension to Magnitude +8, and Final Conclusions", Mary Almond, J. G. Davies and Prof. A. C. B. Lovell conclude their work on the velocity distribution of 1,095 sporadic meteors. The earlier papers on this subject have been briefly discussed in *Nature*, and the present paper gives a brief summary of the work and apparatus. Previous research on the brighter sporadic meteors gave no indication of an appreciable number with hyperbolic velocity, and now, extending the work to faint meteors of magnitude 8, the same results are obtained. Far from moving in hyperbolic orbits, it was found that nearly 90 per cent of all sporadic meteors must be moving in elliptical orbits with periods of about

two years, and the remaining 10 per cent had velocities close to the parabolic limit.

The work of Hoffmeister and Öpik was largely responsible for the belief, which prevailed for some time, that most of the sporadic meteors moved in hyperbolic orbits, although ten years ago Porter had criticized the methods used in the Arizona Meteor Expedition and had come to the conclusion that hyperbolic orbits were relatively scarce—if, indeed, they existed¹. Although the work at Jodrell Bank Experimental Station of the University of Manchester has vindicated Porter's views, it is admitted that "the results do not exclude the possibility that less than 1 per cent may have hyperbolic velocities—a result which may imply an interstellar origin or may equally well be explained on the basis of perturbation within the solar system". Even if this should be verified in future years, there would still remain a very wide difference between meteors which have speeds just above parabolic velocity and those with high hyperbolic velocities, many more than 160 km./sec., which were found in the Arizona Meteor Expedition.

The conclusions attained by Hoffmeister were based on studies of the diurnal and annual variation of numbers of meteors, and it is interesting to know that in a private communication to Prof. Lovell he has shown how his observations can be reconciled with the more recent results of the survey of sporadic radiants by Prentice and by radio-echo measurements by Lovell. McKinley's results from radio echoes at Ottawa² are in good agreement with those obtained at Jodrell Bank, and all those who took part in this important programme must be congratulated on their perseverance and on the important results obtained. These have established practically beyond doubt that hyperbolic meteors, except in cases of perturbations by other bodies in the solar system, are extremely rare or possibly non-existent.

EXPERIMENTAL DEMONSTRATIONS OF BALANCE IN POPULATIONS

By DR. A. J. NICHOLSON

Division of Entomology, Commonwealth Scientific and
Industrial Research Organization, Canberra

THE accompanying graph records the population changes which took place in a culture of *Lucilia cuprina* Wied. held constantly at 25° C. and provided with ground liver for the adults at the constant rate of 0.5 gm. per day. The other consumable requisites, namely, meat for the larvae (from which the adults were excluded) and water and sugar for the adults, were provided in excess each day. As adults live at least as long when supplied with adequate water and sugar as they do when given protein food also, and as protein food is necessary for egg production,

the population was automatically regulated by the effects produced upon egg production by adult competition for the restricted supply of ground liver.

The graph clearly shows an inverse relation between the numbers of adults and the numbers of eggs laid. When the adult population was large, competition for the limited supply of ground liver was so severe that few, if any, adults obtained sufficient for egg production, whereas when the population was small, many obtained adequate supplies and so laid eggs freely. The bimodal form of the egg-generation curves was due to the fact that the population consisted of senile individuals as it approached a minimum, and dominantly of young and vigorous individuals immediately afterwards.

Thus low populations induced the rapid generation of new individuals, whereas high populations suppressed reproduction and so dwindled, with little or no replacement of the individuals that died. Such corrective reaction would have counteracted any departure from the equilibrium density (at which eggs are produced at just the replacement-rate) had there not been a lag of about two weeks between the deposition of eggs and the emergence of the resulting adult flies. This lag between the initiation and operation of reaction produced a violent and sustained oscillation in the population about its equilibrium density, the mechanism being essentially similar to that already described¹ for populations of *L. cuprina* competing for larval food. Although the oscillations resulted from the great disparity existing between the number of births and the number of deaths at almost all times, examination of the data showed that, on the average over a number of complete oscillations, these numbers were virtually equal. It is clear, therefore, that density-induced reaction held the population in a state of balance in its environment.

'Balance' as here used may be defined as a sustained state of corrective reaction to disturbing forces which ensures the persistence of the system. This is normal usage, for it is precisely what we mean when we speak of the balance of a tight-rope walker, or of the balancing of a billiard cue vertically upon a responsive finger-tip. Although 'equilibrium' is one of the senses in which the word is sometimes used, there is no justification for restricting 'balance' to this particular meaning when it is used in relation to population problems, as some biologists do (for example, Solomon²).

Further experiments showed that density-induced compensatory reaction may ensure the continued existence of populations even when subject to great external stresses. The first item in the accompanying table refers to the same culture as the figure, and

	Imposed destruction of emerging adults (per cent)	Mean number of eggs laid per day	Mean number of adults emerged per day	Mean adult population
Adult competition	0	624	573	2,520
	50	732	712	2,335
	75	948	878	1,588
	90	1,361	1,260	878
Larval competition	0	8,794	157	1,252
	75	4,151	192	464
	95	1,921	437	240
	99	1,320	900	128

the next three refer to cultures similar in all respects except that a constant percentage of all emerging adults was destroyed in each. The last four items in the table refer to an otherwise similar group of cultures in which the populations were limited by the provision of only 50 gm. of meat for the larvae in each culture each day. The adults were supplied with excess ground liver, and so could lay eggs freely at all times. In essentials the culture referred to in the fifth item was similar to one previously illustrated¹, and its population oscillated in density with similar violence. All these cultures maintained a state of balance with their environments. Their population patterns were similar to that in the figure, except that the violence of the sustained oscillations decreased with increasing percentages of destruction.

In the first group of cultures the destruction of emerging adults reduced competition, and so permitted a greater number of the surviving individuals to obtain sufficient ground liver to lay eggs; and in the second group the smaller number of eggs laid by the reduced adult population permitted a greater number of the competing larvae to obtain sufficient meat to mature. Consequently in both groups density-governed reaction to increased destruction caused more individuals to emerge on the average each day, as is shown in the table. This in turn caused the reduction of the adult population to be markedly less than the degree of destruction imposed.

In experiments in which other life-stages of *L. cuprina* were destroyed, the same tendency for the immediate effects of destruction to be counteracted by compensatory reaction was observed. Invariably reaction caused more individuals to reach the stage subject to destruction, which in turn caused the densities of some life-stages of the insects to be increased, and those of other stages to be decreased. In general character these results parallel the conclusions reached theoretically in earlier investigations^{2,4} concerning the effects produced by a new destructive factor upon a host population which is governed by the reaction of a specific parasite.

These and other experiments are discussed in greater detail in two articles⁵ which will be published shortly. In one of these it is shown that compensatory reaction to density change is a feature of all kinds of stable population systems, and that it is dominantly responsible for the regulation of populations of all kinds of animals. It is also shown that compensatory reaction is a necessary counterpart of natural selection. Selection by itself merely favours the preservation of the fitter individuals; but, compensatory reaction automatically performs the necessary evolutionary function of eliminating the less-fit individuals, even though these may be so well adapted

that their kind would have persisted indefinitely had the fitter individuals not been present. General arguments leading to this conclusion were given in earlier articles^{2,4}; but the experiments with *L. cuprina* demonstrate the actual existence of the mechanism there postulated.

MECHANISM OF ANIONOTROPY*

By DR. E. A. BRAUDE, D. W. TURNER and
DR. E. S. WAIGHT

Department of Organic Chemistry, Imperial College of
Science and Technology, London, S.W.7

THREE principal mechanisms, which may be labelled unimolecular, bimolecular and intramolecular, have been considered for anionotropic changes¹. Allylic systems, in particular, have received much attention, and although the existence of all three mechanisms now appears to be conceded by most workers in this field, opinions differ in regard to the extent of their incidence.

The unimolecular ionization theory of anionotropy^{2,3}, which postulates reversible dissociation to give 'kinetically free' anions and carbonium-ions and represents the forerunner of the more general hypothesis of unimolecular nucleophilic substitution, was originally based on the results obtained by Burton⁴ in a study of the rearrangement of 1-phenylallyl-*p*-nitrobenzoate (I) to cinnamyl *p*-nitrobenzoate (II). In view of the strong electron-attracting properties of the carbonyl and nitro-groups, a *p*-nitrobenzoate ester certainly represents a relatively favourable case for the occurrence of mechanism (1).

We have re-investigated this reaction in both aqueous and non-aqueous solvents, following the isomerization by the spectrokinetic technique (in ethanol, (I) shows λ_{max} 2565 Å., ϵ 13,800, whereas (II) shows λ_{max} 2535 Å., ϵ 30,700). It soon became apparent that in non-aqueous solvents—for example, in chlorobenzene at 130°—the 'spontaneous' rate of rearrangement was greatly dependant on the method of purification of the ester and of the solvent, and that the reaction is accompanied by the formation of small amounts of *p*-nitrobenzoic acid which could be extracted with water and estimated titrimetrically with ammonia or polarographically, using a platinum microelectrode (Fig. 1). The production of *p*-nitrobenzoic acid had been previously noticed by Meisenheimer⁵, who also reported that the addition of acid had little effect on the reaction. We find, on the contrary, that the rearrangement is greatly accelerated by *p*-nitrobenzoic acid, and that its rate is very nearly proportional to the concentration of acid above c. 0.01 *M* (Fig. 2, curve 1). At extremely low concentrations of acid, however, the first-order rate constants approach a small, limiting value indicating a residual, non-catalytic rate, which is much smaller than that recorded qualitatively by Burton⁴. This

Fig. 1. Elimination of *p*-nitrobenzoic acid from 1-phenylallyl *p*-nitrobenzoate (0.18 M) in chlorobenzene at 130°. In sealed 'Pyrex' glass ampoules (—) and in an unsealed vessel under nitrogen (---).

Fig. 2

part of the curve can only be reached by working under rigorously controlled conditions, with complete exclusion of moisture and acidic impurities. Under these conditions, the first-order rate constants exhibit an upward drift as the reaction proceeds, evidently due to the catalytic effect of the *p*-nitrobenzoic acid produced in the side-reaction. The degree of preference for the catalytic mode of rearrangement is indicated by the fact that its specific rate constant in the presence of *p*-nitrobenzoic acid is greater by a factor of about 100 than that of the uncatalysed rearrangement.

We believe that these experiments constitute the first demonstration of truly thermal rearrangement of an allylic ester in solution. (We have never held the view, ascribed to us by Ingold⁴ and Hughes⁵, that allylic esters will rearrange only in the presence of acids. Our contention, here confirmed, has been that uncatalysed rearrangement is difficult to observe because it is usually swamped by much more facile catalytic processes; see ref. 7.) If the uncatalysed reaction proceeded by mechanism (1), the intermediate carbonium-ions could recombine with partners other than the original *p*-nitrobenzoate ions,

that is, the isomerization would be intermolecular. The simplest alternative is intramolecular rearrangement, as represented in (2).

We have studied the rearrangement in the presence of ¹⁴C-carboxyl-labelled *p*-nitrobenzoic acid as a source of *p*-nitrobenzoate ions. (The acid was prepared by the interaction of *p*-bromonitrobenzene and K¹⁴CN in dry pyridine to give *p*-cyanonitrobenzene, followed by hydrolysis.) The fate of the labelled *p*-nitrobenzoyl group was determined by separating the acid and the two esters at various stages and measuring their specific radioactivity in dimethylformamide solution, using a methane-flow proportional counter. The most significant result is that, at low acid concentrations, the rate of exchange is much less than the rate of rearrangement. This indicates that the uncatalysed, 'spontaneous' rearrangement is intramolecular. Intramolecular anionotropic rearrangement has previously been demonstrated in structurally and environmentally less favourable systems⁷⁻⁹, and it would indeed be most surprising if any other reaction path were followed in the present instance. Why should

a molecule undergo the drastic, energy-consuming step of complete ionization, when it can redistribute its electrons by an internal, synchronized process involving a six-membered cyclic transition state? So far as this particular case, at least, is concerned, the unimolecular ionization theory must surely now be abandoned.

At higher *p*-nitrobenzoic acid concentrations the total rate of exchange rapidly increases (Fig. 2). The larger part of the exchange reaction takes place without rearrangement and must be due to bimolecular substitution by *p*-nitrobenzoic acid or *p*-nitrobenzoate ion at the α -carbon atom. This is analogous to neutral or alkaline hydrolysis in aqueous media, which also proceeds without rearrangement, contrary to the findings of Kanyon, Partridge and Phillips⁸. The smaller part of the exchange reaction takes place with rearrangement, and the difference between curves 1 and 4 (Fig. 2) represents the contribution of the intramolecular isomerization. The acid-catalysed, intermolecular rearrangement which is represented by curve 4 is evidently bimolecular and may proceed by direct attack of undissociated acid molecules at the ethylenic γ -carbon atom of the ester, through a cyclic transition state involving a hydrogen bridge ($R=p\text{-NO}_2\text{C}_6\text{H}_4$):

Alternatively, proton-transfer to the ester to give the oxonium-ion, in which the existing alkyl-oxygen bond is weakened, may precede bimolecular attack, as in aqueous solvents¹. We cannot yet distinguish between these two versions, partly because nothing is known about the ionization equilibria of *p*-nitrobenzoic acid in chlorobenzene, and further investigations, including acidity-function measurements, are in progress.

The non-participation of 'foreign' anions in the rearrangement of 1-phenylallyl *p*-nitrobenzoate is easily shown in the case of bromide ions by the fact that no cinnamyl bromide is formed when the reaction is carried out in the presence of diisobutylammonium bromide. Burton³ sought to demonstrate the participation of acetate ions by heating 1-phenylallyl *p*-nitrobenzoate with acetic anhydride and tetramethylammonium acetate and isolating cinnamyl acetate. However, since reagent-grade acetic anhydride contains acetic acid, and since the two known procedures for the preparation of tetramethylammonium acetate give products which contain acetic acid or water of crystallization¹⁰, there is little doubt that in Burton's experiments the rearrangement was taking place in the presence of acetic acid. Burton states, without details, that 1-phenylallyl *p*-nitrobenzoate could be "left for some months without change in solution in acetic acid, acetic acid containing a few drops of 30% hydrobromic acid and alcoholic hydrochloric acid", but we have found that rearrangement takes place quite rapidly under such conditions. Viewed in this light, Burton's experiments no longer provide evidence for the participation of acetate anions, and, without dogmatizing before further investigation as to what happens in

the solvent acetic anhydride, the result obtained with tetramethylammonium acetate can be interpreted as due to bimolecular γ -substitution by acetic acid, analogous to the intermolecular rearrangement which occurs in chlorobenzene in the presence of *p*-nitrobenzoic acid.

The present results thus support the view^{1,7,11,12} that the rearrangement of allylic alcohols and esters is normally bimolecular, or, in special cases, intramolecular. Bimolecular, non-isomeric rearrangement has also been demonstrated by Kepner, Winstein and Young¹³, and others^{14,15}, in allylic halides. Ingold and his associates^{1,5} have adduced reasons why bimolecular rearrangement (which they term S_N2') should be rare. One of us¹ has pointed out, however, that although bimolecular attack by charged anions at the ethylenic γ -carbon atom will be impeded by the electrostatic repulsion due to the unsaturation electrons, attack by neutral molecules (for example, H_2O , ROH , RCO_2H , NR_3 , etc.) will be far less subject to such an effect. It should also be remembered that intramolecular and bimolecular mechanisms (for example, equations 2 and 3) on one hand, and unimolecular mechanisms (for example, equation 1) on the other, represent extremes of a continuous range of possible time-sequences. It is quite conceivable that in mechanism (2), for example,

the intermediate stage possesses some ion-pair character. Similarly, in mechanism (3), bond-breaking at C_α may be slightly ahead of bond-making at C_γ ; this will leave the whole process essentially synchronized, and the electron displacements will be assisted by the unshared electron pair on the oxygen atom being joined to C_γ . Such a concept is entirely analogous to that of 'hybrid' mechanisms in nucleophilic substitution¹⁶⁻¹⁸.

We are much indebted to Prof. R. P. Linstead for providing us with the facilities for work with radioactive tracers. We also thank the Department of Scientific and Industrial Research for a maintenance grant to one of us (E. S. W.) during 1948-50.

An Unusual Virus Disease of a Dipterous Larva

AN apparent nuclear disease of the larva of the crane fly, *Tipula paludosa*, was briefly described in 1923 by Rennie¹. We have now rediscovered this disease, which seems to be infectious, and have compared it to some extent with the nuclear and cytoplasmic polyhedroses of lepidopterous larvae, from which it differs in some important respects.

In the nuclear polyhedral diseases of lepidopterous larvae, virus rods arise in the chromatic masses of infected nuclei², and are liberated into the clear nuclear ring zone where the polyhedral protein also accumulates. Crystalline polyhedra form in which the virus rods, c. 300 m μ $\times$ 40 m μ , are embedded. This type of polyhedra becomes surrounded by a membrane. In dilute sodium carbonate the polyhedra swell slightly, and, with few exceptions, dissolve readily, freeing the virus rods contained within.

The cytoplasmic polyhedra of the gut contain spherical virus particles³. In a paper now in the press⁴ we have demonstrated, in the case of the larva of the angle-shade moth, *Phlogophora meticulosa*, the interesting fact that the virus particles are composite in nature. The virus bodies are embedded in a matrix of polyhedral protein and measure about 60 m μ in diameter. Each consists of four or five smaller spheres, approximately 12 m μ in diameter. During the course of the disease the small spheres apparently arise first in the cytoplasm and secondarily associate into the larger bodies prior to the formation of the polyhedra. The minimal infectious unit may well be the small particles of 12 m μ diameter. The cytoplasmic polyhedra also dissolve in weak alkali, but partially and in a different manner from the nuclear type. The larger virus bodies readily dissociate into their small component spheres which, on account of their small size, are easily overlooked.

In the polyhedrosis of *Tipula*, a chromatic mass forms in the enlarged nuclei of the blood cells, and from this mass the chromatic material segregates as several spherical bodies, leaving a large eosinophile body in the nucleus; the polyhedra seem to arise around the periphery and are closely applied to the nuclear membrane (Fig. 1). They differ in appearance and may be rectangular or shaped like a segment of an orange. They are negatively birefringent and appear to be genuine crystals. Their behaviour in the presence of different reagents is most unusual and differentiates them sharply from either of the other groups of polyhedra. They are resistant to trypsin and to dilute and weak acids and alkalis. In 1 N sodium hydroxide they elongate to six or more times their length,

Fig. 1. Blood cells from an infected larva of *Tipula paludosa*, showing the polyhedral crystals. $\times 1,500$

becoming first biconvex spindles and then elongating into crescents or worm-like shapes (Fig. 2). At about three times their normal length this elongation is still completely reversible, and in water, at pH 6-8, they return to their original size and shape. After such treatment, however, the polyhedra are 'activated'; in other words, they now respond in a similar manner in ammonia, 1-12 per cent sodium carbonate and hydrochloric acid, pH 1-4; but not to 1 N hydrochloric acid or 25 per cent sodium carbonate. The elongation and contraction or return to normal shape, which take place along the same axis, can be repeated indefinitely in these solutions and take place as rapidly as the solutions can be alternated.

The polyhedra are not usually dissolved even after half an hour in 1 N sodium hydroxide at 20° C. In a solution of equal parts of 1 N sodium hydroxide and 1 N potassium cyanide, the response is speeded up enormously and the polyhedra elongate even further to reach their maximum in 1½ min. They dissolve completely in 2-4 min. The polyhedra give a positive reaction with xanthoproteic and ninhydrin tests, and stain with bromophenol blue after treatment for 15 min. with 1 N hydrochloric acid at 60° C. Their substance is Feulgen-positive throughout, and each polyhedron has intensely staining granular bands at about ½ μ intervals. Tests for sulphur have been negative.

Fig. 2. On left, untreated polyhedra; on right, the same after treatment with 1 N sodium hydroxide and 1 N potassium cyanide for 90 sec. $\times 200$

Fig. 8. 'Ghost' of a polyhedral crystal after treatment for 4 min. with 1 *N* sodium hydroxide, 1 min. 0.5 *N* sodium thiolglycollate (pH 8.4) and 1 min. 1 *N* sodium hydroxide. Note the apparent virus rods $\times 14,700$

In such resistant polyhedra as these, it is a difficult matter to observe any possible virus bodies within. However, we have made studies, on the electron microscope, of polyhedra subjected to various treatments. In one, the polyhedra were exposed to 1 *N* sodium hydroxide and washed. The resulting elongated forms appeared semi-opaque with a granular and fibrous structure. In another series the polyhedra were treated with 1 *N* sodium hydroxide for 4 min., then washed and treated with sodium thiolglycollate at pH 8.4 for 4 min., and finally washed and treated for one minute with 1 *N* sodium hydroxide. Under this treatment, most of the substance of the polyhedral crystal is dissolved, leaving behind a lens-shaped 'ghost'. In many polyhedra treated in this fashion we have observed rod-shaped bodies which could be virus rods (Fig. 3).

Acknowledgments are due to Mr. H. C. F. Newton and Miss Margaret Megaw, of the National Agricultural Advisory Service at Wolverhampton, who sent us the batch of larvae in which the first diseased specimen was found, to Dr. Max Perutz for his determination of the negative birefringence of the crystals, and to Miss Elizabeth Green, of the Cavendish Laboratory, who took the electron micrograph.

Form of Myelinated Nerve Fibres

D'ARCY THOMPSON¹ directed attention to the fact that the shape of a liquid body may be regarded as a 'diagram of forces' acting on it at the moment. As the myelinated nerve fibre is a liquid thread enclosed in a distensible and elastic² neurilemmal tube, it was thought that a thorough determination of its shape might help to reveal some of the forces maintaining the structure and organization of the fibre.

It is essential for the determination of the shape to make measurements on living fibres in which the physical state of axoplasm and myelin remains unaltered and the proportions of different regions are as undistorted as possible. Carefully teased preparations of unstained fibres were used for this purpose. When the teased fibres are allowed to float freely in a chamber some 100–200 μ deep instead of being simply spread out between slide and coverslip, their deterioration is greatly delayed and the shape of the fibres remains unchanged for many hours. The dimensions observed in such conditions presumably do not deviate markedly from those of the fibres in normal physiological surroundings.

The nerve fibre, which is approximately cylindrical along the internodes, presents, as was noticed by Ranvier³, small bulbous enlargements on both sides of the nodes. These enlargements are not symmetrical. One of them is always more bulky and longer than the other⁴ (Fig. 1). In marking the original direction of the nerve at the removal from the body, it was found that the larger bulb is always situated on the proximal side of the node in mixed as well as in purely sensory nerves.

In order to test whether the asymmetry of the bulbs is not an artefact due to the direction of teasing, the nerves were teased in opposite directions

Fig. 1. Photomicrographs of nodes of Ranvier in cat peripheral nerve fibres. Proximal bulbs on the left.

in two sets of experiments. No influence of the direction of teasing could be detected during examination of some six hundred nodes. A bulb situated centrally was larger in fibres teased in both directions.

The inequality of juxtanodal bulbe was observed in peripheral fibres of mice, rats, guinea pigs, rabbits, cats, dogs and frogs. The general occurrence of this phenomenon suggests that the polarity of the bulbe may be a reflexion of some fundamental process going on in all myelinated nerve fibres and merits a closer quantitative analysis. This was carried out on fibres from cat peripheral nerves. The dimensions chosen to determine the shape of the juxtanodal region of the fibre, and allowing for calculation of volumes, are shown in Fig. 2. The mean diameter of the fibre was determined from six measurements taken along the internodes adjacent to the nodal region examined. The results of measurements of more than four hundred nodes were grouped by internodal diameter classes, and mean values and con-

fidence limits of each dimension are presented in Table 1.

It will be seen that the diameters of the proximal bulbe are consistently larger than the corresponding diameters of the distal bulbe. The scatter of longitudinal dimensions is larger than that of diameters, and the difference between P_1 and D_1 is not significant for smaller fibre groups. The calculation of bulbar volumes based on these data reveals a net surplus of material in the proximal bulbe, amounting to 100–2,000 μ^3 , according to the fibre size.

Fig. 2 shows the relative width of characteristic parts of the nodal region as a percentage of the mean diameter of the internode in fibres ranging from 5 to 20 μ in diameter. It was shown previously on rabbit nerves that the neurilemmal tube, relatively inextensible in the nodes, is distensible and elastic over the internodes, and is actually distended by the fibre contents. The normal width of the fibres is determined by an equilibrium between the turgor pressure of the axoplasm and the elastic tension of the neurilemma. In order to evaluate the normal degree of distension of the internodal neurilemma in cat fibres, the excess of material was removed from a limited portion of the fibres by local application of external pressure. Under a gradually increasing external pressure, the fibres in the compressed part contract progressively but preserve their cylindrical outline. When the external pressure exceeds a certain critical value, the fibres become flattened and entirely emptied of their contents. By keeping the external pressure just below the critical value, the 'unstretched' diameter of the nerve tube is obtained. It was measured in 265 fibres and the results, grouped by normal fibre size and calculated as a percentage of the mean normal diameter of the internode, form the lowest curve in Fig. 2. It will be noted that the unstretched diameter amounts to about 40 per cent of the normal diameter in fibres of all sizes. This means that the internodal portions of neurilemmal tubes are distended by the pressure of axoplasm in the same proportions in all fibres. The degree of distension of the bulbar region depends on the diameter of the fibres and decreases with increasing diameter except for the smallest and the largest fibre groups.

Although a full interpretation of the form of the fibres requires further experiments, their morphological polarity seems to provide an additional confirmation of the existence of a proximo-distal flow of axoplasm in the axon. The nodal part of the nerve tube, narrower and less extensible than its internodal portion, creates a resistance to the flow and leads to piling up of material above the node. The situation resembles closely that created artificially by Weiss⁸ in experiments with apposition of a con-

Fig. 2. Relative dimensions in the nodal region of cat peripheral nerves as a percentage of the mean diameter of the internode. The diagram indicates which dimension each of the upper curves refers to: A , mean diameter of the internode; U , unstretched diameter of the neurilemmal tube; P_1 , proximal bulb; D_1 , distal bulb; C , diameter of the node.

stricting sleeve on the nerve. The morphological result is also similar in both cases.

Observations on Experimental Anthrax: Demonstration of a Specific Lethal Factor produced *In vivo* by *Bacillus anthracis*

AN ENIGMA in the study of the cause of death in anthrax has been that no lethal endo- or exo-toxin has been found in cultures of the organism¹⁻³. Recently, we have been able to demonstrate a factor in the plasma of guinea pigs dying of anthrax which is not only lethal but also specifically neutralized by anthrax antiserum. This communication describes briefly work which has led to this finding. A fuller report will be published elsewhere.

In previous studies⁴⁻⁶, a mixture of the plasma (approximately 1 part) and peritoneal and thoracic exudates (approximately 5 parts) was collected from guinea pigs dying of anthrax for studies of the chemical basis of the virulence of *B. anthracis*. It was shown that large volumes of this plasma-exudate and extracts of the organisms separated from it were non-lethal to guinea pigs when injected intraperitoneally. The conclusion was reached that the products of *B. anthracis* growing *in vivo* were not markedly toxic. This agreed with the fact that large numbers (approximately 1×10^8 chains per ml.) grew in the blood of a guinea pig before death resulted. It was suggested that death followed the action of harmful effects which were weak, relative to the number of organisms producing them. One such effect was the slight tissue-damaging activity shown in this and previous work⁷.

Attention then turned to the significance of the massive terminal bacteraemia in the death of normal guinea pigs. This topic was important in view of reports^{8,10} that some animals of other species die of anthrax without a marked bacteraemia. Guinea pigs (700 gm.) were infected intradermally with *B.*

anthracis (strain N.P.). On the third day, and in the twelve hours preceding death, the number of organisms in the blood rose from $0.2-0.4 \times 10^8$ to $0.5-1.0 \times 10^8$ chains per ml. There was a remarkably constant relationship between the bacterial count of the blood and the interval before the host's death. The administration of streptomycin abruptly terminated the bacteraemia, and provided the latter had not increased beyond 3×10^6 per ml., the animals were saved (20/23 with $0.7-1.5 \times 10^6$ per ml. of blood). All guinea pigs having a bacteraemia greater than the critical level (47/47 with $0.7-1.5 \times 10^7$ per ml.) died 1-3 days later, although free from active infection. These experiments showed conclusively that a bacteraemia appeared to be an essential factor for death, but the fate of the guinea pig was determined when the blood-stream invasion had reached only 1/300 of its maximum. This finding almost certainly renders untenable the views that death from anthrax might be due to mechanical blockage by the organisms or to a deficiency in the host of oxygen, etc.

An insight into the probable nature of the lethal product of *B. anthracis* was provided by chemical examination of the blood, histological examinations and clinical observations on guinea pigs at their death, both from active infection and later, after this had been removed by streptomycin. A raised haematocrit and total blood nitrogen, lowered plasma protein, the presence of anuria, delayed clotting of blood, terminal collapse with subnormal temperatures $85^\circ-89^\circ$ F. and histological and chemical evidence of acute nephrosis were noted. These observations and others as yet incomplete provided sufficient evidence for a working hypothesis that the animals died 'in shock'¹¹. This agrees with the known oedematous and haemorrhagic nature of anthrax and with the fact that guinea pigs, which die two to three days after the bacteraemia has been stopped by streptomycin, have acute renal failure (plasma constituents were: protein nitrogen, 373; non-protein nitrogen, 179; urea, 311; phosphorus as inorganic phosphate, 18; and calcium, 7.5 mgm. per 100 ml.; presence of anuria and severe nephrosis).

This evidence emphasized the importance of an oedema-producing factor. We therefore re-examined the distribution and activity of the tissue-damaging factor. Filtered heparinized plasma from guinea pigs dying of anthrax (strain N.P.) was much stronger in this respect than the plasma-exudate formerly used⁶. Plasma (0.2 ml.), when injected intradermally into test guinea pigs, produced an extensive area of oedema and congestion (40 mm.), and a positive reaction still resulted from a dilution of 1/25 of the material.

Table 1. SPECIFIC LETHAL EFFECT OF PLASMA FROM GUINEA PIGS DYING OF ANTHRAX

Anthrax plasma injected (vol. in ml.)	Mice (18-22 gm.) (Figures show the number of deaths in batches of 5 mice)												Guinea pigs (250 gm.) (number dead) (number treated)			
	Intravenously						Intraperitoneally						Intravenously		Intra- peritoneally	
	1 0	1 0	0.5	0.5	0.25	0.25	1 0	1 0	0.5	0.5	0.25	0.25	6	6	8	6
		+ a.s.*		+ a.s.		+ a.s.		+ a.s.		+ a.s.		+ a.s.		+ a.s.

Total deaths %	100	Nil	80	Nil	40	Nil	73	Nil	53	Nil	7	Nil	53	Nil	28	44

* a.s. means that anti-anthrax horse serum (half to a third the volume of the plasma) was allowed to react with the anthrax guinea pig plasma at room temperature before injection.

Volumes of 1 ml. or greater were injected into mice in 0.5-ml. aliquots at several hour intervals.

Guinea pigs were injected into the jugular vein using a local anesthetic.

Adequate control groups of mice and guinea pigs were injected with appropriate volumes of normal guinea pig plasma with the addition of lysed red cells (equivalent to the 10-15 per cent haemolysis usual in the plasma of guinea pigs dying of anthrax). No deaths occurred.

Tests on samples of plasma taken at intervals during the bacteremia showed that this tissue-damaging activity increased regularly with the increase in the numbers of organisms in the blood. Anthrax antiserum (horse; Weybridge spore vaccine; produced by our colleague, F. C. Belton) neutralized the skin reaction completely. When the peritoneal exudate was found to be low in tissue-damaging activity, an explanation was revealed for the relatively low activity of the mixture of plasma and exudate previously used. This had consisted largely of exudate.

The possibility of a specific lethal effect of the undiluted plasma was now investigated. Table 1 summarizes the results of four experiments with mice and guinea pigs injected intravenously and intraperitoneally with the plasma. The resulting deaths, coupled with the absence of deaths in control animals and in those receiving plasma mixed with the anthrax antiserum, shows clearly the lethal nature and specific character of the factor present in such plasma. A higher death-rate and a shorter survival-time indicated that the plasma was more effective intravenously than by the intraperitoneal route which had been used in previous studies⁶. Finally, animals dying in these experiments showed the same symptoms of oedema, collapse with subnormal temperatures, and of nephrosis as did infected animals.

Phosphate Partition and Turnover in Human Red Cells

PHOSPHATE partition and turnover in the human red cell can be studied by paper chromatography, which permits unequivocal separation of the organic phosphate compounds involved in carbohydrate metabolism.

In the following experiments, 20 ml. of heparinized whole blood was incubated at 37° C. with about

Fig. 1. Relative specific activity (counts/min./μgm. phosphorus/ml. packed cells) against time. Key to curves: IP, inorganic phosphorus; 2,3-DPG, 2,3-diphosphoglycerate; ATP, adenosine triphosphate; F16, fructose-1,6-diphosphate; ADP, adenosine diphosphate.

50 μc. of sodium dihydrogen phosphate (³²P) and samples removed after varying times, the whole system being kept mixed and at constant pH by the introduction of 95 per cent oxygen, 5 per cent carbon dioxide. The red cell samples were packed by centrifuging and washed twice with an isotonic phosphate buffer of pH 7.4 after removal of the buffy coat. All centrifuging was carried out at 2,500 g for 15 min. The cells were then hemolysed with water and saponin, and the stroma separated by high-speed centrifuging after buffering the solution to pH 4.2 with an acetate buffer¹. After removal of the supernatant fluid, the stromal fraction was further washed twice with the buffer. Trichloroacetic acid extracts could then be made from both the stroma and intracellular contents of the cells and treated chromatographically in the manner described by Caldwell². Location of individual spots was carried out with a scanning counter, and these were cut out and their radioactivities assayed by conventional methods. The total phosphorus in each spot was estimated by the method of Berenblum and Chain³.

In this way, relative specific activities of the following compounds can be plotted against time: adenosine triphosphate, adenosine diphosphate, fructose-1,6-diphosphate, 2,3-diphosphoglycerate, and inorganic phosphorus. With normal cells the curves shown in Fig. 1 are given.

It is obvious that a pool of glycolysis exists in the stroma separate from that in the intracellular fraction, since their activities do not show a parallel change. Also, in the intracellular fraction, 2,3-diphosphoglycerate shows a precursor relationship with adenosine triphosphate. This relationship is opposite to the findings of Gourley⁴, who used methods involving partial hydrolysis of cell extracts to characterize each intermediate compound. Our findings would necessitate the operation of Rapoport's mutase⁵ and the coenzyme action of 2,3-diphosphoglycerate in the conversion of 3-phosphoglycerate to 2-phosphoglycerate⁶. Since the phosphorus atom attached to the first carbon atom of 1,3-diphosphoglycerate is transferred to adenosine diphosphate by the 1,3-diphosphoglycerate phosphokinase⁷, it is reasonable that 2,3-diphosphoglycerate, which is in equilibrium with the latter, should show a precursor relationship to adenosine triphosphate. These relationships will be discussed more fully at a later date when further observations will be reported.

This technique provides a simple method for studying simultaneously the effects of various substrates on the phosphate compounds of the red cell. For example, adenosine, known to be utilized by red cell hemolysates⁶, can be shown to be differentially metabolized by the stroma and intracellular fractions of normal and certain pathological cells⁶.

One of us (T. A. J. P.) wishes to thank Dr. L. E. Young for giving facilities for this investigation. The communication is based in part on work performed under contract with the U.S. Atomic Energy Commission, at the University of Rochester A.E.C. Project.

Highly Purified Choline Acetylase

THE enzymatic synthesis of acetylcholine in the mammalian organism is inextricably linked with the general metabolism, especially with the general acetylating reactions. Hence it may be more rational to restrict the term 'choline acetylase' in its application to an enzyme which catalyzes the reaction between choline and 'active acetate' or acetyl-coenzyme A, as shown in the following equation:

According to Balfour and Hebb¹, there are two routes for biological synthesis of acetylcholine in mammalian tissues, namely, the acetate- and the citrate-utilizing system respectively.

Quite independently of Balfour's studies, we have already reported² a similar observation on a system synthesizing acetylcholine, in which emphasis was laid on the difference in the distribution as well as localization of both systems in mammalian tissues. Characteristically enough, the citrate system was found to be present abundantly only in nervous tissues, in contrast with the overall distribution of the acetate system in all tissues yielding acetylcholine. The universality of the acetate system was also demonstrated by the following observations. All the water-soluble extracts of such tissues as those listed in Table 1, which *per se* could scarcely synthesize acetylcholine, were shown to contain an accelerating factor enhancing the enzymatic synthesis of acetylcholine by guinea pig brain extract with acetate. In acetylcholine synthesis with citrate, on the other hand, we could not find any significant amount of such an accelerating factor.

The accelerating factor effective in the acetate system may be identical with the acetate-activating

Table 1. ACCELERATING EFFECT OF SOME TISSUE EXTRACTS ON THE SYNTHESIS OF ACETYLCHOLINE

Tissue	No. of Exp.	Substrate	
		Acetate	Citrate
Dog ventricular muscle	11	166 ± 6 per cent	109 ± 3 per cent
Guinea pig kidney	5	188 ± 11 " "	111 ± 3 " "
Guinea pig ventricular muscle	2	158 ± 8 " "	108 ± 1 " "
Guinea pig liver	2	128 ± 8 " "	111 ± 6 " "
Guinea pig skeletal muscle	1	136 " "	112 " "
<i>Escherichia coli</i>	1*	180 " "	" "
Control		100	100

Control mixture contained 3 μ M adenosine triphosphate, 1.0 unit (for acetate system) or 0.8 unit (for citrate system) coenzyme A, 4 μ M choline, 140 μ M (for acetate system) or none (for citrate system) potassium chloride, 8 μ M (for acetate system) or 5 μ M (for citrate system) magnesium chloride, 15 μ M cysteine, 1 μ M ascorbic acid, 5 μ M sodium fluoride, 8 μ M phosphate, 10 μ M acetate or citrate and dialysed water-soluble extract derived from 10 mgm. of freeze-dried powder of guinea pig brain. In testing mixture, fractionated extract of tissue listed above (30–40 gm./dl. fraction by ammonium sulphate) was added (* extract itself was used). pH 6.8. Final volume 1 ml. Incubated for 60 min. at 37° C. Figures indicate the amount of synthesized acetylcholine in testing mixture, expressed as a percentage of the control sample.

system or adenosine triphosphate-acetate reaction system described by Lipmann³. To verify this assumption, we had to separate choline acetylase from the acetate-activating system; this was accomplished by the following procedure, carried out at 4° C. or lower:

PREPARATION OF CHOLINE ACETYLASE	
1 gm. freeze-dried powder + 10 ml. M/50 phosphate of brain (pH 6.8)	
Residue discarded	← Centrifuged for 20 min. at 1,500 g.
Residue discarded	← Supernatant acidified with acetic acid to pH 4.5 and chilled for 5 hr. or more at 0° C.
	Clear supernatant (see text) neutralized to pH 6.8.
Residue discarded	← Ammonium sulphate added to final concentration of 15 gm./dl.
Supernatant discarded	← Ammonium sulphate added to final concentration of 35 gm./dl.
Residue made up to 1 ml. with M/50 phosphate (pH 6.8) and dialysed against M/50 phosphate (pH 6.8)	
Residue discarded	← Acidified with acetic acid to pH 5.0 and chilled for 30 min. at 0° C.
	Supernatant neutralized to pH 6.8.

The choline acetylase thus prepared had lost almost completely its power to yield acetylcholine. However, when extract of kidney or *Escherichia coli* and other organisms were added, it regained its power to synthesize acetylcholine (Table 2). This implies that we have succeeded in separating choline acetylase almost completely from the acetate-activating enzyme system without losing its activity.

Further evidence was given by the following experiments (Table 3). Choline and 'active' acetate or acetyl-coenzyme A, prepared by the method of Littlefield and Sanadi⁴, yielded acetylcholine under the influence of our choline acetylase without further addition of coenzyme A, adenosine triphosphate and acetate.

Our method of separating choline acetylase is also applicable to fresh brain tissues; but freeze-dried powder of guinea pig brain always gives the most satisfactory results. Under the most appropriate conditions, 1 mgm. of our choline acetylase was

Table 2. SYNTHESIS OF ACETYLCHOLINE BY COUPLING CHOLINE ACETYLASE WITH THE ACETATE-ACTIVATING ENZYME SYSTEM

Example	Preparation	Acetylcholine synthesized ($\mu\text{gm./ml. hr.}$)
1	Complete system Choline acetylase (20 mgm./ml.) Kidney extracts* (15 mgm./ml.)	7.5 < 0.05 < 0.05
2	Complete system Choline acetylase (20 mgm./ml.) Kidney extracts* (15 mgm./ml.)	12.5 0.07 < 0.05
3	Complete system Choline acetylase (20 mgm./ml.) <i>Escherichia coli</i> extracts (40 mgm./ml.)	9.5 < 0.05 < 0.05

Details as in Table 1, except enzyme source. Figures in parentheses indicate the amount of freeze-dried tissue powder used.

* 20–40 gm./dl. fraction of ammonium sulphate was used.

Table 3. SYNTHESIS OF ACETYLCHOLINE FROM CHOLINE AND ACETYL-COENZYME A BY CHOLINE ACETYLASE

	Acetyl-coenzyme A yielded by	Acetylcholine synthesized ($\mu\text{gm./ml.}$)
1	Guinea pig kidney (75 mgm.)	4.25
2	<i>Escherichia coli</i> (45 mgm.)	2.20

Each sample contained 4 μM choline, 8 μM cysteine, 8 μM phosphate and acetyl-coenzyme A. Extract of freeze-dried powder of kidney or *Escherichia coli* was incubated with adenosine triphosphate, coenzyme A, potassium and magnesium ions, cysteine and acetate at 37° C. After 90 min. incubation, the mixture was added to pH 8.5 and heated at 80° C. for 2 min. From this mixture active acetate or acetyl-coenzyme A was prepared by the method of Littlefield *et al.* (ref. 4). Figures in parentheses indicate the weight of the freeze-dried tissue used.

shown to synthesize 0.5 mgm. of acetylcholine an hour when coupled with the acetate-activating enzyme system.

In the course of preparing choline acetylase, it is worth noticing that the supernatant still contained a considerable amount of the citrate-activating system, after the first acidification in the preparation of choline acetylase, though the acetate-activating system had already been excluded almost completely.

Further purification of choline acetylase is now in progress; details of the present experiment will be published elsewhere.

Evidence for the Occurrence of Glucose Dehydrogenase in Yeast

WHEN buffered suspensions of washed bakers' yeast are incubated anaerobically with methylene blue, dehydrogenase activity as measured by the rate of decolorization is greater with glucose than it is with other substrates. While investigating the action of nicotine on various dehydrogenase systems, including those of yeast, we found that, whereas nicotine inhibited dehydrogenase activity of *Saccharomyces cerevisiae* with glucose, activation resulted with glucose-6-phosphate as substrate.

For these experiments we used cells harvested from young—not more than one day old—actively growing cultures. Before preparing the final suspensions in phosphate buffer, they were washed and aerated in suspension for two hours at 37° to reduce the dehydrogenase activity due to endogenous metabolites. Dehydrogenase activities in the presence of added substrate and triphenyltetrazolium bromide were measured at 30° and pH 7.6 by the method of Fahmy and Walsh¹.

For experiments using glucose-6-phosphate as substrate the cell membranes were first ruptured by alternately freezing and thawing, as the substrate was otherwise unable to penetrate the cells. Experiments showed that this procedure, though reducing dehydrogenase activity with glucose, did not influence the effect of nicotine; thereby demonstrating that the inhibitory action of nicotine was not due to its preventing the substrate from entering the cell.

Inhibitions up to 20 per cent by nicotine (0.01 *M*) were recorded with glucose. Activations up to 40 per cent by nicotine (0.01 *M*) were recorded with glucose-6-phosphate.

In view of these results, it became of interest to investigate the effect of nicotine on the hexokinase reaction. Partially purified hexokinase^{2,3} was prepared from yeast. Activities were measured at 30° in bicarbonate buffer, pH 7.5, by the method of Colowick and Kalckar³ using the Warburg apparatus. Nicotine (0.01 *M*) had no effect on the transfer of phosphate from adenosine triphosphate to glucose.

The significance of these findings is best appreciated by reference to the diagram.

Fluoride (0.01 *M*), which does not inhibit hexokinase⁴ or glucose-6-phosphate dehydrogenase⁵, inhibits glucose dehydrogenase activity of yeast by 30–40 per cent.

So far as we are aware, glucose dehydrogenase has not hitherto been reported as occurring in yeast.

In its behaviour towards nicotine, we find that the glucose dehydrogenase activity of yeast resembles that of the enzyme⁶ in mammalian liver. Liver glucose dehydrogenase was prepared and purified by the method of Brunelli and Wainio⁷. Its activity was measured by determining the oxygen uptake of a system containing, in addition to the enzyme, glucose, coenzyme I, Straub's heart flavoprotein⁸ and methylene blue. Nicotine (0.01 *M*) inhibited by 15–18 per cent.

Glucose dehydrogenase activity, similarly inhibited by nicotine, occurs also in *Torulopsis utilis*.

Oxidation of Glutathione in Extracts of Lens in the Presence of Ethylenediaminetetraacetate

CHELATING agents are being increasingly used for removing traces of metals. We therefore think it worth while to report a case where a chelating agent accelerated the oxidation of a substance which it was intended to preserve in the reduced state.

We extracted cattle lens with a neutral solution of ethylenediaminetetraacetate (EDTA, versene, sequestrene) to give a final concentration of 0.0087 *M* ethylenediaminetetraacetate with the object of removing traces of metals and thereby keeping the glutathione present in the extract fully reduced. We found that ethylenediaminetetraacetate promoted the oxidation of glutathione, which was stable in its absence for at least five days at 4° C. (Exp. 1, 2). The oxidation in ethylenediaminetetraacetate extracts was much slower in nitrogen (Exp. 3). Glutathione was not oxidized in the presence of 0.0013 *M* ethylenediaminetetraacetate unless the lens extract was also diluted (to 1 in 15) (Exp. 4, 5). There was no change in protein sulphhydryl measured by titration with *o*-iodosobenzoate.

of ascorbic acid in lens extract remained almost unchanged for two days in the presence of ethylenediaminetetraacetate while glutathione was oxidized, but ascorbic acid was decreased on the fifth day when there was little glutathione left in the solution. Ascorbic acid is stable for at least five days (Exp. 2) in the absence of ethylenediaminetetraacetate. Further evidence pointing to ascorbic acid as the substance which directly causes glutathione oxidation is the fact that if ascorbic acid is removed from a water extract of lens by dialysis, and ethylenediaminetetraacetate and glutathione are then added to it, the glutathione is stable (Exp. 6); but if ascorbic acid is also added, oxidized glutathione is formed (Exp. 7). This takes place in either a water or in an ethylenediaminetetraacetate extract of lens (Exp. 8).

It is quite difficult to remove oxidized glutathione completely from lens proteins. It dialyses rather slowly out of lens extracts (Exp. 9), and repeated precipitation of lens protein with 50 per cent ammonium sulphate takes down relatively more oxidized glutathione than reduced glutathione (Exp. 10). We thought at first that the loss of glutathione in extracts of lens made in ethylenediaminetetra-

Glutathione was estimated by the nitroprusside reaction¹ or by glycylase²; oxidized glutathione was estimated after electrolytic reduction to glutathione³. Ascorbic acid was estimated by titration with 2:6 dichlorophenolindophenol after precipitation of protein with metaphosphoric acid. Lens extracts were prepared from the lenses of freshly killed cattle by grinding with sand, extracting with twice their weight of fluid and centrifuging at 7,000 *g* for 5-10 min.

A solution of glutathione in 0.0087 *M* ethylenediaminetetraacetate is more stable than a solution in water, which suggests that oxidation of glutathione in ethylenediaminetetraacetate extracts of lens is secondary to some other reaction, such as the oxidation of ascorbic acid. This is known to be catalysed by ethylenediaminetetraacetate in the presence of metal ions and oxygen¹. A lens extract normally contains both ascorbic acid and glutathione, and it is therefore possible that when ethylenediaminetetraacetate is added to such an extract it catalyses the oxidation of ascorbic acid, which is then non-enzymically reduced by glutathione which itself becomes oxidized. Experiment 1 shows that the level

acetate might indicate formation of a protein-glutathione compound similar to the compound of glutathione and glyceraldehydephosphate dehydrogenase described by Krimm and Racker⁴. Glutathione could be liberated from this compound by boiling, and we have found that boiling will regenerate glutathione in lens extracts (Exp. 11). But it is known that if oxidized glutathione is heated with proteins it becomes reduced through reaction with protein-sulphydryl groups, and it is clearly this reaction that takes place when stored ethylenediaminetetraacetate extracts of lens are boiled.

It is possible that ethylenediaminetetraacetate will have a similar effect in extracts of tissues other

than lens and so destroy the substance its presence is intended to preserve.

Lipid Nomenclature

CONSIDERABLE confusion exists in the naming of compounds of the class now most commonly referred to as 'lipids'. It is indeed not yet agreed that the latter shall be the generic name, and the terms lipins, lipines, lipides and lipoids are in current use, together with derivative forms, galactolipins, etc., used to designate the complex members of the class. A profusion of empirical nomenclature has developed, particularly in the complex lipid field, often referring to compounds of dubious existence, and terms are frequently applied without distinction both to a single compound and to a crude 'fraction' containing this compound or possessing similar solubility properties. Several authors have directed attention to this state of affairs^{1,2}, and have made proposals for rectifying some of the anomalies.

Folch-Pi and Sperry¹ have suggested the replacement of the older system of classification, in which the phosphorus-containing lipids or phosphatides were divided into the monoaminophosphatides (lecithin and cephalin) and diaminophosphatides (sphingomyelins), by a division into phosphoglycerides, phosphosphingosides and phosphoinositides. The former use of the term 'phosphatide' to cover all the phosphorus-containing lipids is rejected in favour of a system in which the diacylglycerophosphoryl radical is termed 'phosphatidyl', 'lecithin' becoming 'phosphatidyl choline' and the 'cephalins' 'phosphatidyl serine', 'phosphatidyl ethanolamine', etc. This classification is very convenient and has won ready acceptance by many workers. The diacylglycerophosphates are already referred to as 'phosphatidic acids', which is in conformity with the proposed usage, although the former term seems preferable as being definitive and is not too cumbersome. 'Phosphoglycerides' is not very satisfactory as a name for the group, suggesting the 'phosphatidic acids' rather than their esters with hydroxyamino compounds. It is therefore suggested that it is replaced by 'phosphoglyceratids'. In view of the recent synthesis³ of lipids in which glycol replaces glycerol in a lecithin type of structure, 'phosphoglycerolates' or 'phospholates' is suggested as a suitable term, 'phospholatidyl choline', for example, designating an acylglycolphosphorylcholine. The retention of 'ol' in the latter term involves a minor inconsistency with the phosphoglyceratids, in which the 'ol' of glycerol is omitted. However, the alternative, 'phosphoglyceratids', might involve confusion with sugar derivatives.

The term 'phosphosphingoside' proposed to replace sphingomyelin is very misleading, since the '-oside' termination suggests a glycoside and would lead to confusion with the sphingoglycosides (*q.v.*). An alternative term which would indicate the connexion with the phosphoglyceratids would be 'phosphosphingatids', although objection could be justifiably

Older terms	Alternative proposals in the literature	Present proposals
Lipid, lipide, lipin, lipine and derivatives Monoaminophosphatides Lecithin, cephalin	Phosphoglycerides Phosphatidyl choline Phosphatidyl ethanolamine, etc. Glycollecithins (ref. 3)	Lipid and derivatives, for example, phospholipid, galactolipid, etc. Phosphoglyceratids Phosphoglyceratidyl choline or phosphatidyl choline Phosphoglyceratidyl ethanolamine, etc. Phosphoglycerolates or phospholates Phosphoglycerolatidyl choline or phosphatidyl choline, etc. Phosphosphingamides or phosphosphingamides Phosphosphingamyl choline or phosphosphingamylidyl choline, etc. Sphingolipids Sphingoglycosides
Di- and triaminophosphatides Sphingomyelins	Phosphosphingosides Sphingolipids (ref. 4) Glycosphingosides Sphingoglycosides	Sphingolipids Sphingoglycosides Sphingamides
Cerebrosides	—	—
Ceramides	—	—

raised that no O-acyl group is present. It might therefore be more desirable to use a term such as 'phosphosphingamides', leading to 'phosphosphingamidyl choline' for the sphingomyelins already known, or, for a given individual, 'N-lignoceryl-phosphosphingamidyl choline' and allowing scope for extension as compounds of this structure, but involving other bases, are discovered or synthesized. However, the objection raised to 'phosphoglyceride' would apply to this term, and 'phosphosphingamitide' might overcome this point.

Lignoceryl-sphingosine and similar sphingosine amides at present styled 'ceramides' might be more suitably named 'sphingamides'.

Since the structures of the compounds termed 'phosphoinositides' by Folch-Pi and Sperry have not been established with any certainty, any attempt to include these in an analogous terminology would be premature.

Carter and Colmer (*loc. cit.*) prefer the term 'sphingoglycosides' to 'glycosphingosides', which was proposed by Folch-Pi and Sperry to replace 'cerebrosides'; and since, as the former authors point out, the compounds are glycosides, the point seems well taken.

It would seem to be extremely desirable for the appropriate International Union to go into the whole question of lipid nomenclature, in order that a generally acceptable terminology might be adopted.

Sex Ratio in Spawning Populations of *Lampetra planeri*

THE question of the sex ratio in lampreys is of some interest in view of the occurrence of hermaphrodite gonads in the ammocoete larva; but there are wide divergencies in the figures given by previous workers in Europe and North America.

My own observations on *L. planeri* show that the ratio varies in different streams and even from year

Table 1

Year	Total seen or captured	No. of visits	No./visit	Males	Females	Ratio: male/females
1947	83	3	28	60	23	2.6
1949	64	5	13	35	29	1.2
1950	126	6	21	90	36	2.5
1951	182*	8	23	100	46	2.2
1952	118*	7	16	56	33	1.8
1953	197*	9	22	143	54	2.6

* Total includes animals not sexed.

to year, and suggest that such variations may be responsible for these conflicting reports.

Table 1 records the results of systematic observations on the River Yeo (north Somerset) over a period of six years and, except for 1947, these observations were maintained from the first appearance of the adults in late March or early April to their final disappearance at the end of April. Visits were spaced at intervals of three or four days, and on each occasion a complete search was made of the restricted stretch of the stream where the animals occur. As an objective index of relative frequency the number of animals seen or captured per visit is to be preferred to the total number, as the latter takes no account of the varying durations of the spawning season and differences in the number of visits made from one year to another.

The total figures for the six years give a ratio of 2.2, and on only one day in the whole period has the number of females exceeded the males, while for more than half the observation days the males have exceeded the females by more than 2:1.

The records do not bear out the findings of Zanandrea¹ that the excess of males increases as the season advances, or his suggestion that this is due to the greater survival-rate of the male. In 1951, when spawning reached its peak later than in any other year, the ratio was 2.2; yet in 1950, when it occurred some three weeks earlier, the proportion of males was even larger (2.5). Moreover, if the numbers are grouped as weekly totals the smallest proportion of males is to be found in the last week of the spawning season.

The annual variations in sex ratio are interesting when compared with the estimates of relative total numbers. Thus, in the years 1949 and 1952 when the total population was smallest the sex ratio was only 1.2 and 1.8 as against 2.6, 2.5 and 2.2 in the years when the total population was greater. Excluding 1947, when only three visits were made, the number of females in any one year varied only from 29 to 54 as against 35 to 143 for the males. Variations in total numbers have therefore been due in large part to variations in the number of males.

Collections from a small area in south-east Somerset in 1938 and 1939 consisted of 139 males and 129 females, and in each year the sexes were present in nearly equal numbers². These local and annual differences in the sex ratio suggest that the orientation of sex in the ammocoete is influenced by environmental conditions such as temperature and nutrition.

Note added in proof. The results recently obtained for 1954 are consistent with those of previous years in showing a low ratio of males to females (1.6) with a relatively small total population (total 126 and number observed per visit 16). M. W. HARDISTY

A Violet Pigment from the Mediterranean Medusa *Rhizostoma pulmo*

In the subtentacles and marginal bodies of the Mediterranean medusa *Rhizostoma pulmo* a violet pigment occurs which can be extracted by means of distilled water at 2°–4°. By filtering and evaporating to dryness the deep violet-coloured solution in vacuum, and redissolving it three or four times, we finally obtained an amorphous violet residue, insoluble in common organic solvents, but giving with antimony trichloride in chloroform a blue carotenoid-like reaction. The violet colour is constant between pH 1.4–10.0. Over and below this pH it becomes pink. Addition of hydrogen peroxide decolorizes the solution. The violet solution shows a bluish fluorescence in ultra-violet light, and a characteristic absorption spectrum with three peaks at 6150 Å, 5750 Å and 5250 Å (Fig. 1).

On heating the pigment solution over 50° it becomes brownish-yellow with precipitation of denatured protein and simultaneous disappearance of the absorption bands.

The pigment is probably a conjugated protein with a prosthetic group belonging, or related, to the carotenoids. This conclusion is adopted because of the similarity of the reaction with antimony trichloride, and the decolorization with hydrogen peroxide, as also to the resemblance of the spectrum.

Further researches are in progress.

Investigations concerning the composition of the mesogloea from *Rhizostoma pulmo* have produced evidence that its proteins are very poor in total nitrogen (20–28 mgm. per cent nitrogen) and is partially conjugated with silicon.

Fig. 1

Fig. 2. 1, Phenylalanine; 2, isoleucine; 3, leucine; 4, tyrosine; 5, valine; 6, proline; 7, methionine; 8, arginine; 9, lysine?; 10, alanine; 11, glycine; 12, serine; 13, threonine?; 14, unidentified; 15, ammonium salts; 16, aspartic acid; 17, glutamic acid; 18, glucosamine

Chromatograms show that the jelly tissue yields, after hydrolysis, in addition to glutamic acid, leucine, isoleucine, valine, aspartic acid, arginine, perhaps lysine, proline, methionine, alanine, glycine, serine, an amino-acid travelling with threonine, and at least two unidentified amino-acids of which one (No. 18) could be (it is not yet definitely proved) glucosamine (Fig. 2).

Chromosome Counts in Tunicates and a Modified Method for making Permanent Squash Preparations

WHEN collecting tunicates at the Marine Biological Station at Roscoff (Brittany) we wondered whether it would be possible to introduce the cytogenetical element into tunicate systematics. To this end we tried acetocarmine squashes after preliminary soaking in distilled water as recommended by Makino and Nishimura¹. The method worked well; but owing to the small size of cells and chromosomes our microscope outfit did not provide a sufficient resolving power. We then made permanent preparations for examination at home. The method of Makino and Nishimura¹ for making permanent squash preparations not giving satisfactory results, we modified the method and adopted the following procedure.

(1) Dissect the material in distilled water and leave it to soak for a few minutes. (2) Transfer to cold acetocarmine (40 per cent glacial acetic acid) and leave the material to fix and stain for at least thirty minutes, but in general no longer than forty-five minutes. Should the material be left too long in the acetocarmine or should it be heated in it, it will not squash well. (3) Place the fixed and stained material on a heavily albuminized slide. (4) Moisten one side of a piece of 'Cellophane' with albumin and place the

Fig. 1. Microns in *Aspidium proterum*

'Cellophane' on the material, the moistened side downwards. Flatten out creases and remove air bubbles. (5) The material under the 'Cellophane' is now rolled out by means of a glass rod or squashed by application of pressure with a cover-slip. (6) Heat the slide gently by passing it over a small flame a few times, then place it quickly in a dish with distilled water. The heating should be just sufficient to allow for the coagulation of the albumin close to the slide. If the heating was insufficient the material will come off together with the 'Cellophane' in the distilled water. If the heating was too great the 'Cellophane' will not come away and the material may be damaged. The correct amount of heating, which

Fig. 2. Microns in *Siphon elegans*

Fig. 3. Meiosis in *Pyura microcosmus*

can only be learned by personal experience, ensures that the 'Cellophane' floats off, while the squashed material adheres to the slide. (7) Dehydrate and mount in the ordinary manner.

Employing this procedure, we made permanent acetocarmine squash preparations of whole abdomens of *Aplidium proliferum* (Milne Edwards), *Sidnyum elegans* (Giard) and *Sidnyum turbinatum* (Savigny) and of pieces of gonads of *Pyura microcosmus* (Savigny). These were examined in Amsterdam with the aid of a fluorite oil-immersion objective.

We found suitable stages of meiosis in preparations of *Aplidium proliferum* (Fig. 1), *Sidnyum elegans* (Fig. 2) and *Pyura microcosmus* (Fig. 3). Our count for *Aplidium proliferum* was $n = 14$, for *Sidnyum elegans* $n = 9$ and for *Pyura microcosmus* $n = 8$.

So far as is known to us this is the first instance in which chromosomes have been observed in tunicates. Although the tunicates are far from ideal for cytogenetical work, on account of the small size of the chromosomes, such cytogenetical work does not seem impossible.

Our modified method for making permanent squash preparations has also been tried with fair results on botanical material (anthers). Botanical material may require a different staining procedure.

Distribution and Chromosome Number of *Allium paradoxum* in Gloucestershire

There is only one record of *Allium paradoxum* (M. Bieb.) G. Don. in the 'Flora of Gloucestershire' (p. 465; 1948). During a study of the ecology of this population at Bartonbury, other centres have been located near Chesterton and on the Bath Road. The chromosome number of the species has been investigated in Feulgen squashes¹ of root tips treated with mono-bromo naphthalene², and in aceto-carmine¹ and Feulgen squashes¹ of anthers. The chromosome number found in the Bartonbury populations is $2n = 16$. Pollen grain mitosis has been observed in detail and records are as follows:

Plants	Pollen grains at metaphase	Haploid chromosome number

Hatchability of Hen Eggs and Lymphomatosis

It is widely accepted that poor hatchability is one of the main causes of financial loss to poultry breeders. Judging from the results regularly reported by many large hatcheries, the national hatching-rate of all eggs set in Great Britain seems to be between 65 and 70 per cent.

The failure of an egg to hatch may be due—apart from defects in the incubator—to infertility or to some factor, often a nutritional deficiency, which causes the developing embryos to die at varying stages during the full term of twenty-one days. Fertility is now accepted as a heritable factor¹ and has no obvious relationship with embryonic mortality, although by many poultry breeders the two conditions are regarded under the one heading of 'hatchability'. There are some grounds for this in that attention to one factor, for example, fertility, usually leads to greater attention to the other and, as a consequence, improved fertility is often accompanied by lower embryonic mortality. Moreover, it is impossible merely by candling to distinguish between infertile eggs and fertile eggs in which very early embryonic death has supervened.

Lymphomatosis is a further cause of reduced profits in the poultry industry, and in its several manifestations is probably responsible for approximately 25 per cent of the adult mortality among domesticated fowl in Britain². In endeavouring to breed lines resistant to this disease, it was observed that those dams which appeared most satisfactory on grounds of high egg numbers and high hatching-rate of all eggs set most frequently proved to be those having progeny among which the incidence of lymphomatosis was greatest. In consequence, these families were discarded. Inspection of the records over the several years revealed the fact that a remarkably close correlation between high hatchability and the incidence of lymphomatosis in the

¹ Makino, S., and Nishimura, I., *Stain Tech.*, **27**, 1 (1952).

Table 1. HATCHING RESULTS WITH DAMS THE PROGENY OF WHICH HAD NO LYMPHOMATOSIS OVER FIRST EIGHTEEN MONTHS OF THEIR LIVES

	Eggs set	Infertile	Hatch of fertile eggs	Per cent
1950	897	149	639	85
1951	1,189	306	656	74
1952	1,243	152	809	74
1953	2,668	248	1,877	81

HATCHING RESULTS WITH DAMS THE PROGENY OF WHICH EVINCED LYMPHOMATOSIS OVER FIRST EIGHTEEN MONTHS OF THEIR LIVES

	Eggs set	Infertile	Hatch of fertile eggs	Per cent
1950	1,492	76	1,279	90
1951	2,309	381	1,908	80
1952	1,786	178	1,235	79
1953	985	110	758	86

progeny of dams evincing high hatchability was apparent each year since lymphomatosis became manifest in the flock (Table 1).

Inquiries among a small number of flock owners who keep complete records have indicated that a similar parallelism is found. Lymphomatosis is present in varying degrees of intensity in the flocks of most breeders in Britain although in many the incidence on the farm is extremely low. Pedigree breeders rarely have post-mortem examinations carried out on every bird dying, still less on birds culled as 'poor doers', although such birds may be affected by lymphomatosis. Nevertheless, many breeders are reluctant to breed from full sister groups where one bird or more has died or has had to be culled. It may therefore be that, if this policy no longer operated, the incidence of lymphomatosis—already high—might become higher, and progress towards improved hatching-rates among first-class pedigree breeders may be possible only when the full implications of lymphomatosis are more fully understood.

The relationship between the disease and hatching-rates is not obvious and further investigations are being pursued by us.

Relationship of Oestrogen and Progesterone in Oestrous Behaviour of the Ewe

It has been clearly demonstrated that for oestrus to accompany ovulation in the sheep the animal must have been under progesterone influence for several days¹⁻⁴.

In attempts to elucidate this phenomenon two series of experiments were conducted between June 1952 and December 1953 at the State Research Farm, Werribee. In the first series, twelve ovariectomized Suffolk cross-bred ewes were used in two groups, A and B, of six ewes each. Each group received the same level of oestradiol benzoate in oil, one group also receiving 75 mgm. progesterone, in six divided injections each of 12.5 mgm. for three days, commencing five days before oestrogen injection. Treatment was repeated at fourteen-day intervals for three treatments at each level of oestrogen, from 5 mgm. successively down to 8 µgm. by a factor of 0.2. At the end of each six-week period the groups were

switched; that group which had received oestrogen alone for the three preceding treatments received progesterone before each of the succeeding three treatments, and vice versa. The level of 8 µgm. was below the threshold for response, so the level was raised to 20 µgm. for the three concluding treatments.

At no level of oestrogen injection was it possible to induce oestrus regularly in a high proportion of ewes treated. When progesterone preceded oestrogen, regular cycles of oestrous behaviour were readily induced by all levels of oestrogen down to 40 µgm. A level of 20 µgm. appeared marginal. Between the limits of 5 mgm. and 40 µgm. oestradiol benzoate, the number of ewes treated, the number and the percentage responding, of progesterone-oestrogen and oestrogen-treated animals were: 96, 86, 90 per cent and 72, 21, 29 per cent, respectively. Progesterone pretreatment advanced the time of onset of oestrus by 12-24 hr.

The second series of experiments consisted of seven assay-type trials, involving seventy-two ovariectomized cross-bred Suffolk ewes, conducted at 4-weekly intervals from June until December 1953. All ewes were primed midway between each trial with 50 µgm. oestradiol benzoate. Dose-response lines were obtained for progesterone-oestrogen and oestrogen alone. In the last two trials, direct comparisons were made, using criteria of oestrous behaviour and vaginal smear change. Progesterone pretreatment reduced the median effective dose of oestradiol benzoate, for oestrus from 64 µgm. to 22 µgm. (99 per cent fiducial limits 52-81 and 19-26), and for vaginal cornification from 24 µgm. to 14 µgm. (99 per cent fiducial limits 20-28 and 10-17). When progesterone preceded oestrogen, the nature of the reaction appeared changed: the dose-response line was steeper and the onset of oestrus earlier.

It is concluded, therefore, that oestrus in the ewe is under dual progesterone-oestrogen control and that this accounts for the phenomenon of 'silent oestrus', or ovulation without oestrus, which occurs at the first ovulation of the breeding season, or when ovulation is induced by gonadotrophin injection in anoestrus.

Full details of these experiments are being published elsewhere, where acknowledgment will be made to the various individuals and organizations who have given valuable aid in this research.

Presence and Absence of the Pre-Natal Check in Lambs' Birthcoats

Fraser, with Hamada¹, has stated that non-N-type and N-type lambs differ in the presence of the pre-natal check in the former and its absence from the latter, and this view is adopted by Waddington².

Sickle-fibres constitute the most easily perceived evidence of the pre-natal check²⁻⁴. Of ten N/+ N-grade lambs studied in a number of body regions, all had sickle-fibres on the shoulder patch and shoulder,

and they were present on several necks, withers, sides and backs, but not on any britch. On eight of the shoulder patches fine sickle-fibres were present.

Sickle-fibres are less plentiful on *N/N* lambs. They have been recorded before on the side (D. A. Ross and F. W. Dry), but they have not been found on the back (Janet M. Ross and Wright). On only one of six *N/N* lambs examined recently on seven positions have sickle-fibres been found anywhere but on the shoulder patch, namely, chalky sickle-fibres on the neck and side, and fine sickle-fibres on the shoulder patch region. Seven of twelve additional *N/N* lambs had sickle-fibres on the shoulder patch region; none of these was fine sickles. Super-sickle-*B* fibres, which have part of the neck region fine and non-medullated, also reveal the presence of the pre-natal check. They have been found on several body regions of a number of homozygotes. Sickle-fibres are easy to find on recessive-*N*'s, but the details need not be given now.

Sickle-fibres have been found low on the leg of six weeks' old *+/+*, *N/+* and *N/N* lambs. The covering looked like that of a short-coated wild sheep, but the hind-legs of Romneys can come later to be more or less woolly down to the hoofs.

In a specimen out from the hip of a three weeks old Mouflon, kindly supplied by Mr. P. G. Schinckel, of Roseworthy Agricultural College, a pre-natal check is revealed by an array tentatively called saddle. Fibres with an apical end approaching the characteristic sickle form, but less sharply curved at the butt of the apical curve and becoming finer more gradually, have a finely crimped neck region and, doubtless following the birth point, become coarser basally. The pre-natal check is thus recognized in a wild sheep. By contrast, in a specimen from the pelt of a nine-day Barbary lamb, for which we are also indebted to Mr. Schinckel, there is nothing to interpret as evidence of a pre-natal check, although some of the short finest fibres, which are crimped, have an apical curve faintly suggestive of a sickle-end.

There is need for much more work and thought on the mechanism of the pre-natal check and its place in the evolution of the fleece.

Delayed Implantation in the Harbour Seal, *Phoca vitulina* L.

PUBLISHED observations on harbour seals generally have indicated the belief that mating in this species, at least in temperate zones, occurs in August and September, with a peak in September. The reasons for this apparently are twofold. First, the animals seem to be more gregarious at hauling-out sites in August and September than at other times of the year, and display more than the usual amount of quarrelsome and noisy activity then. This has

been taken to indicate sexual activity, and seal hunters have reported apparent acts of copulation at this time. Secondly, small embryos taken in October and November are of such a size as to suggest that implantation took place in August or September. Schaffer and Slipp¹ give the curvilinear length of an embryo taken in Washington State between September 12 and 15 as 103 mm., and state that spermatogenesis begins early in July. Havinga² gives the length of the smallest embryo seen by him as 10 cm., taken in December, and states that mating in Dutch waters takes place in August and September. Imler and Sarber³ state that while the mating season is unknown, embryos taken in Alaska from a fraction of an inch to about 1½ in. in length are found from mid-October to well into November. Fisher⁴ reported that the testes of a large male harbour seal taken in British Columbia on September 25 were sexually active, and thought that mating occurred at this time of year.

During the past few years, harbour seals from Nova Scotia and New Brunswick have been examined at St. Andrews, N.B., as a part of general life-history studies of pinnipeds on the Canadian east coast. A series of forty-eight reproductive tracts of adult female harbour seals taken from May to October since 1950 has yielded interesting information on the reproductive cycle in this species. Whelping in Nova Scotia and New Brunswick waters occurs in May and June with a peak early in June. A study of the ovaries has revealed that the corpus luteum of pregnancy in gross appearance persists throughout lactation (two to three weeks) as a large body, which looks functional, although it displays from late pregnancy early microscopic signs of retrogression similar to those outlined by Harrison, Matthews and Roberts⁵. Grossly visible signs of retrogression, with large mature follicles generally in the opposite ovary, have been noted as early as June 13. By early July retrogression is advanced, and new corpora lutea have been found as early as July 3. From this date until September 19, a well-spread series of thirty specimens shows a large (although smaller than maximum size attained) new fully filled-in corpus luteum in each set of ovaries, no mature follicles, and no evidence of implantation or embryonic development. Two reproductive tracts taken on September 20 and 21 each contained a typical implantation site in one cornu of the uterus, consisting of a small bulbous swelling about the size of a marble. One specimen on October 3, two on October 7, and one on October 11 contained embryos 4 mm., 9 mm., 15 mm. and 17 mm. long respectively. A series of embryos taken from this date until March shows progressive development from these sizes. No sexually mature females without embryos have been taken after September 20.

It appears, therefore, that harbour seals in the waters of Nova Scotia and New Brunswick, and probably elsewhere in similar latitudes, mate immediately upon the termination of lactation late in June or early in July, and that implantation is delayed until September. No evidence of copulation at any time has been obtained, and it is felt that copulation must take place chiefly in the water. There are the usual noisy gatherings of seals in August and September at hauling-out sites, but these it seems cannot be attributed to sexual activity.

Evidence gathered and being gathered by other workers in this field^{6,7} indicates that the phenomenon of delayed implantation is the rule in the family

Phocidae and probably in the eared seals as well. The results of work being carried out by other investigators on Arctic species should be available before long to help complete the picture.

A fuller treatment of the material mentioned here, together with the results of histological examination of a series of testes now in progress, will be presented in a later paper.

Evolution and Epistemology

PROF. E. SCHRÖDINGER's recent book¹ discussing the relevance of ancient Greek thought to present-day scientific philosophy touches on very many of the problems which have been debated throughout the whole history of Western civilization. He closes it (p. 94) with the thought, adumbrated perhaps already by Democritus (see p. 80), that "for the purpose of constructing the picture of the external world, we have used the greatly simplifying device of cutting our own personality out, removing it . . . this is the reason why the scientific world-view contains of itself no ethical values, no aesthetic values, not a word about our own ultimate scope or destination, and no God, if you please".

But has not recent biological thought added to the picture a factor which Schrödinger fails to take into account? We believe now that the intellectual-sensory apparatus by which we make contact with the external world arose through a process of evolution. According to classical neo-Darwinian views, the process by which it came into being, and acquired the characteristics which it has in man, depended on the occurrence of random changes which were selecting according to their effectiveness in furthering the reproductive ability of the individual animals concerned. If this is true, it is no longer adequate to frame a discussion in terms of a dichotomy between "our personality" and an impersonal world which we arrive at by "cutting our personality out". The faculties by which we arrive at a world view have been selected so as to be, at least, efficient in dealing with other existents. They may, in Kantian terms, not give us direct contact with the thing-in-itself, but they have been moulded by things-in-themselves so as to be competent in coping with them.

I believe one can go further than this in asserting a congruity between our apparatus for acquiring knowledge and the nature of the things to be known. I have suggested² that evolution operates not so much by the differential reproduction of chance variations of phenotype, but by the selection of genotypes which endow their possessors with the capacity to react adaptively with their surroundings (adaptive being defined in terms of reproduction). From this point of view it is easier to envisage the possibility

that our mental equipment is not merely one that happens to be reasonably efficient, but that it has been shaped precisely to fit the character of those things with which it has to make contact. If this were so, the fundamentals of "our personality" must still be implicit in the scientific world-view, and attempts to find them there (such as a tentative one of my own³) cannot be dismissed as impossible of fulfilment.

Forecasting Weather from Solar Radiation

I FEEL that the burden of Dr. C. E. P. Brooks's review of my recent paper (see *Nature*, Dec. 12, p. 1089) does me injustice.

I claim the discovery of a family of periodic variations, more than twenty in number, all to within 1 per cent, integral sub-multiples of 22½ years. For meteorological applications it makes no difference how I was led to make this claim. The question is: Does this family of periods occur in meteorological records?

In my paper in *Smith. Misc. Coll.*, Vol. 122, No. 4, 1953, a single illustration, Fig. 19, demonstrates five of these periods in the precipitation at Albany, N.Y., namely, 45½, 22½, 15½, 11½ and 9½ months. The range of these periodic variations is from 7 to 25 per cent of normal precipitation at Albany. In another paper, *Smith. Misc. Coll.*, Vol. 101, No. 1, 1941, I show that another of the periods, ½ of 22½ years, is associated with changes of temperature at Copenhagen, Vienna and New Haven, from 1800 to 1932, amounting to 1.2 deg., 1.1 deg. C., and 1.3 deg. F., respectively. Also in *Smith. Misc. Coll.*, Vol. 111, No. 13, 1949, I claim two periods in New York and Washington temperature. I now see that, to within one part in 8,000, these are 1/1,250 and 1/2,500 of 22½ × 365½ days.

By adding together in proper phases the effects of twenty-two periods on the precipitation at Albany, I make a prediction, thirty years in advance of its basis, for 41 months, 1928-31, which gives a correlation coefficient of 75 ± 7 per cent. I also add the effects of more than twenty periods, based on Washington temperature records of 1854-1939, which, according to Dr. Brooks, enables a prediction for 18 months of 1952 and 1953 to make a 2 for 1 score.

It seems to me that such results deserve fairer consideration than the saying: "But even granted that the solar constant does vary, the variations found by Dr. Abbot are so small—only one or two per cent—that their direct effect on surface temperatures would be barely perceptible". As stated above, the question, Does a family of periodicities, integrally related to 22½ years, occur in weather?, is quite independent of the question, Does this family occur in solar variation?

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PRINCIPAL SCIENTIFIC OFFICER (with a first- or second-class honours degree in engineering, mathematics or physics, or equivalent qualifications) in the DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH, Mechanical Engineering Research Laboratory, East Kilbride, near Glasgow, to lead a small team on work initially concerned mainly with the general field of stress analysis, both analytical and experimental, and later including vibration and photo-elasticity.—The Civil Service Commission, Scientific Branch, 80 Old Burlington Street, London, W.1, quoting B.4315/54 (May 12).

ASSISTANT LECTURER (Grade B) in GEOLOGY to teach the subject to degree level.—The Registrar, Nottingham and District Technical College, Shakespeare Street, Nottingham (May 15).

SENIOR LECTURER (graduate in pharmacy, with adequate teaching and research experience) in PHARMACOLOGY, and ASSISTANT LECTURER, Grade B, in (a) PHARMACOLOGICAL CHEMISTRY, and (b) CHEMISTRY, at Brighton Technical College.—The Director of Education, Education Office, 54 Old Steine, Brighton 1 (May 15).

ASSISTANT, Grade A (honours graduate in physics) in the APPLIED SCIENCE DEPARTMENT, to teach physics and mathematics up to advanced level G.C.E.—The Clerk to the Joint Education Committee, Wolverhampton and Staffordshire Technical College, Wolverhampton (May 17).

ASSISTANTS (2) (with a sound training in laboratory methods, both physical and chemical, and preferably with some fundamental training and experience in biological work) for work on the composition of fruits in connexion with research on the storage life and quality of apples.—The Secretary, East Malling Research Station, near Maidstone, Kent (May 17).

JUNIOR PHYSICIST to assist in physical and clinical work with radioactive isotopes.—The Secretary, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W.3 (May 22).

LECTURERS or SENIOR LECTURERS in MATHEMATICS, BOTANY, CHEMISTRY, and a LECTURER in CROP HUSBANDRY, at the University College of the Gold Coast.—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 22).

SENIOR PRINCIPAL SCIENTIFIC OFFICER (with first- or second-class honours degree or equivalent in mechanical or aeronautical engineering, with considerable engineering experience, and preferably with some knowledge of guided missiles or rocket propulsion, and a theoretical knowledge of gas dynamics), in the ROYAL AIRCRAFT ESTABLISHMENT ROCKET PROPULSION DEPARTMENT, to direct research and development work on liquid propellant rocket motors.—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting O.247/54A (May 22).

HEAD (with appropriate academic and teaching experience, and also with industrial and research experience) of the DEPARTMENT of METALLURGY.—The Registrar, College of Technology, Suffolk Street, Birmingham (May 28).

LECTURER/SENIOR LECTURER in PETROLOGY at the University of Sydney, Australia.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, May 29).

READER in RADIOCHEMISTRY.—The Registrar, University Office, 46 North Bailey, Durham (May 29).

LECTURER or ASSISTANT LECTURER in PHYSIOLOGY at the University of Malaya, Singapore.—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (May 30).

CHAIR of PHYSICAL or INORGANIC CHEMISTRY.—The Secretary, Queen's University, Belfast (May 31).

DEMONSTRATORS (3) (with a first- or second-class honours degree in chemistry, and a RESEARCH ASSISTANT (with at least two or three years experience in postgraduate research work) in the DEPARTMENT of ORGANIC CHEMISTRY.—The Registrar, The University, Liverpool (May 31).

LECTURER (with special qualifications in organic chemistry) in CHEMISTRY in St. Salvator's College.—The Secretary, University of St. Andrews, College Gate, St. Andrews (May 31).

LECTURER in PATHOLOGY.—The Secretary, University College, Cork, Ireland (May 31).

METALLURGIST (with a recognized degree in metallurgy, and preferably with one or two years industrial experience) at the Naval Research Establishment, Halifax, Nova Scotia, for duties which will include the examination of service metallurgical failures (ferrous and non-ferrous) in R.C.N. Ships, and undertake metallurgical research in the field of the improvement of metallurgical components in warships.—The Defence Research Member, Canadian Joint Staff, 66 Ennismore Gardens, London, S.W.7 (June 1).

LABORATORY TECHNICIAN (with wide experience in biochemical and/or chemical laboratories) in the DEPARTMENT of BIOCHEMISTRY, John Curtin School of Medical Research, Australian National University.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (June 7).

CHAIR of PHYSIOLOGY in the University of Sydney, Australia.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, June 30).

SENIOR LECTURER in METALLURGY at the University of Otago, Dunedin, New Zealand.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (New Zealand, July 1).

SENIOR LECTURER in PHYSICS at Rhodes University, Grahamstown, South Africa.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, July 1).

AGRONOMIST (with at least a second-class honours degree, and not less than two years appropriate postgraduate experience, preferably including acquaintance with tropical crops and up-to-date knowledge of the statistical analysis of field experimental results), at the West African Cocoa Research Institute, Gold Coast, to assist in laying down field experiments on various methods of cultivating cocoa.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting Z7059/130.

ASSISTANT, Grade B (with a good honours degree of a British university, and preferably with teaching experience to degree standard) in the DEPARTMENT of PHYSICS.—The Principal, Technical College, Queen Street South, Huddersfield.

ASSISTANT LECTURER (graduate in physics, engineering or chemical engineering, and preferably with experience in the food industry)—The Registrar, National College of Food Technology, Cranwood Street, London, E.C.1.

DEMONSTRATOR in GEOLOGY.—The Registrar, The University, Nottingham.

REGULERS and PHYSICISTS (particularly with electronics), Senior Scientific Officer and Scientific Officer grade (with an appropriate first- or second-class honours degree, or equivalent high professional attainments) in Royal Naval Scientific Service Experimental Establishments in the London, Portsmouth, Weymouth and Gloucestershire

areas, and in Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), 28 King Street, London, S.W.1, quoting A.946/52A.

FISHERIES OFFICERS (with a university degree in natural science) in the Gold Coast, to assist in the general development of marine and freshwater fisheries (Ref. ODB.65/13/01), and in the Northern Region of Nigeria to demonstrate and develop simple fish farming (Ref. ODB.149/14/02). The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting appropriate Ref. No.

MASTER or FRANCHISEMATE to advanced and scholarship level—The Headmaster, Bishop's Stortford College, Bishop's Stortford.

PHYSICAL CHEMIST (preferably with research experience on polymerization) to undertake fundamental research on resin finishes on textiles—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

PHYSICIST (with a first- or second-class honours degree in physics, and wide experience of high-speed photography including operation of electronically pulsed timing circuits) at the Ministry of Supply Designing Establishment, near Sevenoaks, Kent, to take charge of a small section employing photographic and optical techniques in investigation of transient phenomena associated with explosives—The Ministry of Labour and National Service, Technical and Scientific Register (K), 28 King Street, London, S.W.1, quoting A.103/54A.

PRINCIPAL SCIENTIFIC OFFICER (with first- or second-class honours degree in physics or equivalent qualification, and undertaken several years responsible research work) at the Atomic Weapons Research Establishment, Aldermaston, to supervise a group engaged on research and development work in relation to problems involving radioactive materials—The Administrative Officer, Recruitment, Atomic Weapons Research Establishment, Aldermaston, quoting 78/WGB/24.

SCIENTIFIC OFFICER, Grade 2 (with professional/academic qualifications, and preferably with industrial experience in metallurgy) in the Metallurgy Division at Derby—The Director of Research (Railways), British Railways Research Department, Staff Section, 222 Marylebone Road, London, N.W.1.

SCIENTIFIC OFFICER (with first- or second-class honours degree in physics or electrical engineering) at an R.A.F. Station near High Wycombe, Bucks, for operational research duties, and theoretical studies in the field of communications and general electronics—The Ministry of Labour and National Service, Technical and Scientific Register (K), 28 King Street, London, S.W.1, quoting A.100/54A.

SOIL CHEMIST (with a good honours degree in chemistry, preferably with training and experience in soil chemistry) in Kenya, to analyse soils in connexion with research into the uses of fertilizers on crops, and into the development of areas of irrigation—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODB.63/7/017.

ZOOLOGIST, Senior Scientific Officer or Scientific Officer grade (with first- or second-class honours degree), for general and experimental work on marine plankton—The Director, Marine Station, Millport, Isle of Cumbrae, Scotland.

Isomantle

... an Electric Hotplate with resilient surface, avoiding breakage to glassware, it accommodates the actual shape of the vessel base. Being inert to most chemicals, it is unaffected by accidental spillages.

The lightest warming plate ever made.

ISOPLATE ISP/1 200 watts; heating surface 6 in. diameter; weight only 1 lb. 5 oz. £3 5 0d.

ISOPLATE ISP/2 400 watts; heating surface 8 in. diameter; weight only 2 lb. 3 oz. £5 10 0d.

This is one of the many Laboratory Heaters described in Catalogue LHM which we shall gladly send on request: for Plant Mantles see Catalogue PLT

ISOMANTLES are built to last; they are simple to run, efficient, and of neat appearance. Guaranteed for 12 months and patented (Nos. 645843, 664301).

HOTPLATE...

A short history of gratiules—No. 4

Spiders' webs & acid

The Spider's Web is recorded as being used by Prof. F. Fontana of Florence in the year 1755. Cross-wires made of spiders' webs were in popular use for very nearly two centuries—indeed, up to quite recent times many instrument manufacturers kept special spiders for the making of these fine cross-wires.

The etching of glass with hydrofluoric acid was discovered by Scheele in 1771. Unfortunately, we have not been able to trace precisely when it was first suggested that instead of ruling the pattern with a diamond in glass, it should be ruled in a wax resist and the resultant stencil etched with H.F. At any rate, in the nineteenth century extremely fine rulings were being made mechanically by this method, the wax resist being displaced by a silver film deposited on glass in 1880 by Burton and Grubb.

DEFENCE RESEARCH AND THE NATIONAL ECONOMY

DR. O. H. WANSBROUGH-JONES, chief scientist in the Ministry of Supply, stated in a lecture to the Royal Society of Arts last year that the relation between the scientist and the Armed Services in Great Britain is satisfactory, and scientific advice is being rendered normally and effectively up to the highest levels. Concern, as expressed in the recent debates on defence in Parliament and elsewhere, is rather with the other aspect of defence research—its cost and the disposition of our available resources between defence research and civilian research. Even when full allowance is made for the great value to British industry and to science, to which Dr. Wansbrough-Jones testified, of much of the scientific research and development carried out on behalf of the Services, the level of that expenditure provokes the question whether it is not already too high.

The "Statement on Defence, 1954"* puts the expenditure of Britain on defence research and development in 1954-55 at nearly £160 million, or, according to the Prime Minister, about double that in 1951-52. No analysis of the distribution of this research effort between the different Services or Ministries is attempted in the analysed defence budget, although the distribution of the total expenditure on production and research is shown. Only general comments are made on the complicated character of new weapons coming into use and the need for developing entirely new techniques before successful laboratory experiments issue in practical weapons for the Armed Services. The time required for the various stages of research, development and production tends to increase, and the weapons themselves are extremely and progressively expensive.

These are the factors which have prompted the suggestion that even now we are spending too little on research and development, and which make so difficult the decision how best to divide available funds between improvements—and possibly major improvements—in current weapons and equipment, and research and development on new weapons. As to the nature of the new developments, the Statement says little. Good progress has been made with the development of a fighter aircraft the speed of which well exceeds that of sound, and a research aircraft of this type is expected to fly within the next twelve months. The new fighters now being introduced into the Royal Air Force will in due course be equipped with powerful air-to-air guided weapons which will perhaps quadruple their fighting power. Good progress is being made in the development of surface-to-air guided weapons, and these developments are being supported by continual improvements in arrangements for detecting incoming enemy aircraft and in the control and reporting system generally. In land warfare, the effects of research and development policy are to improve the efficiency of the ground forces rather than to make

it possible to reduce numerical strength. At sea, the introduction of the steam catapult and angled deck has made possible the operation of aircraft of much higher performance from aircraft-carriers. These developments, together with the great improvements in methods of anti-submarine detection and in naval weapons generally, will greatly increase the ability of the Royal Navy to carry out its main function of controlling sea communications.

It is obvious that the Statement on Defence contains far too little information to permit informed public discussion of defence policy and of the soundness of the actual compromises on which the Government has decided. As Lord Alexander of Hillsborough pointed out, the ordinary citizen can form no idea where these defence expenditures will lead us. To some extent this is inevitable; but something could well have been said, within the limits of security, to indicate why there is no mention of the replacement programme by new construction which a year ago the First Lord of the Admiralty said is vital if the Royal Navy is to exist as a balanced and efficient fighting force. Enough was said in the debates in Parliament to show the wisdom of giving the nation the fullest possible reasoned statement, at least where a fundamental change in the traditional role of one of the Fighting Services is contemplated. There should be no secrecy for secrecy's sake.

Quite apart from the concern which has been provoked by the explosion of the hydrogen bomb since the defence debates began, and the probable need for a revision of the priorities laid down in the Statement on Defence, the Government should go to the limit in taking the public into its confidence in this matter of defence development and research. When the Select Committee on Estimates reviewed the national expenditure on research and development in 1947, the Defence Research Policy Committee had only just been constituted. Annual reports from such a Committee are not to be expected; but little, if anything, has since been published to show that the weaknesses relating to defence research and development revealed by the inquiry have been removed. The position in regard to atomic energy had, of course, been transformed before the Atomic Energy Corporation Bill was presented to Parliament; but in insisting that, if it is to discharge its duty, Parliament needs to be provided periodically with 'progress reports' setting out the range, aims and progress of Government research activities, the Select Committee made no exception for defence. The very magnitude of the increase in expenditure on defence research and development is a further reason for implementing its strong recommendation that those estimates should be reviewed independently at more or less regular intervals. At seven years such a review is overdue.

This is not the inquiry for which Lord Alexander of Hillsborough pressed in the debate on the Statement on Defence in the House of Lords on March 16. That was rather for an inquiry into defence policy and its formulation, which, as Lord Swinton rightly observed, is one of the most important functions of the Government and a duty which no Government could

* Statement on Defence, 1954. Pp. 26. (Cmd. 9075.) (London: H.M. Stationery Office, 1954.) 1s.

possibly devolve on anyone else. Even an inquiry which would dispel misgivings apparent in the debate as to the balance of expenditure on man-power and on production, research and development might go too far in that direction.

In any event, substantial support was forthcoming in the House of Lords debate for the view that the balance is about right. Lord Alexander of Tunis, the Minister of Defence, remarked that the next three or four years would see the completion of many of the major projects towards which our research and development programme has been directed for some years; he referred also to the indispensable co-operation of Australia in our weapon research and development, and pointed out that, while in 1950 about one-third of our total defence expenditure went on production, research and development, in 1954, out of a total expenditure nearly twice as great, almost half was on production and defence research. With an expenditure which has thus almost trebled in four years, it is only reasonable that Parliament should have at least such assurance as the Select Committee on Estimates could give that all possible sources of duplication of effort or waste of resources have been eliminated, the weaknesses indicated by the earlier inquiry removed and that no departmental prejudices or conservatism are giving rise in the fresh circumstances to new sources of inefficiency or waste.

The Minister of Defence spoke wisely of the need for making full use of our imagination in dealing with the difficult problems now confronting us without losing sight of present realities and needs, and of the importance of a forward-looking policy in making the best use of the defence resources of Britain in an era of scientific progress. This more limited inquiry, however, could have its part in steadying public opinion and engendering confidence as to the balance of our effort not only in the field of defence but also between our defence effort and that in other fields. This is especially true of research and development, where any serious distortion can well retard progress both in the field of defence and that of industrial and economic development. Moreover, as Lord Hore-Belisha insisted, a defence programme on a purely national basis is anachronistic. He believes that within the Atlantic Treaty Organization there is room for much closer cohesion to prevent overlap in research and the production of weapons.

Since the debates on the Statement on Defence, further information regarding the hydrogen bomb explosions have given point to this criticism. Assurances have been forthcoming from scientists and from the chairman of the United States Atomic Energy Commission that the tests are not beyond control or limitation. It seems clear, too, that they have strengthened President Eisenhower's argument for a greater sharing of knowledge between the United States and Britain and her other partners in the defence of the free world.

While, however, from the point of view of advancing knowledge, the hydrogen bomb and like experiments are necessary and are being carried on with due

regard to all reasonable safeguards, both legal and scientific, it may still be asked whether we have not in fact reached, or approximated to, the point of no return. The purpose of continued experiment is to prevent any potential enemy of the free world from gaining a completely decisive lead. It may be argued that atomic weapons have already reached a stage at which it is meaningless to speak of a decisive lead. Here it needs to be remembered again that the limited resources of Britain do not permit us to provide our Armed Forces with all those things which they would wish to have. The Minister of Defence, too, stressed the limitations of our resources and, bearing in mind what Dr. Wansbrough-Jones said about the efficiency of our system, it is most unlikely that any tests have been or will be made beyond those essential to the design of reliable and manageable weapons. The tests are extremely costly and laborious, and those responsible for carrying them out are acutely aware of the pressure for financial economies, which is just as strong in the United States as in Britain.

There is every reason for scientists to do what they can to urge the freer exchange of information on atomic energy and the reduction of the area of secrecy regarding defence research and development to the narrowest limits consistent with security. Responsible public discussion of these questions by them could do something to help steady public opinion, and to make clear that so far as atomic weapons are concerned the only alternative to developing a sufficient supply of effective weapons of this type as deterrents is, not to refuse to have anything to do with them, but to secure an agreed acceptance of effective control. To outlaw the atomic or the hydrogen bomb is meaningless without a system of enforced law, the first condition of which is the clear knowledge of facts which only a constant and vigilant inspection in every country could supply.

Such a system the United States and Great Britain and other members of the United Nations, except only the U.S.S.R. and its satellite States, have consistently been prepared to accept. President Eisenhower has since made his offer for the pooling of supplies of uranium, thorium and other materials in the hope of providing a new means to agreement and understanding, and possibly later to full international control of atomic energy. Until, however, the abatement of suspicion permits the adoption of an agreed system of prohibition in which both sides have full confidence, it would be folly not to strive to ensure that at least equal striking power remains in the hands of the less secretive and less aggressive side. The Statement on Defence and debates in Britain show clearly how large is the responsibility of statesmen for securing the political conditions in which, if not disarmament, at least the sharing of information, research and production could lighten the burden of defence on individual nations. It is no less clear how much depends also on the scientist, in order that the resources made available for defence may be used most efficiently and to the greatest advantage, not merely of the Armed Forces but also of the national economy as a whole.

CIRCULATION IN THE NORTH ATLANTIC OCEAN

By HENRY STOMMEL

Woods Hole Oceanographic Institution, Massachusetts

SIXTEEN years ago there appeared in *Nature*¹ an announcement of plans for a five-year co-operative programme for the study of the circulation in the North Atlantic Ocean.

The first part of this programme, to be performed by the *Atlantis*, research vessel of the Woods Hole Oceanographic Institution, was to make periodical hydrographic traverses across the Gulf Stream from Montauk Point on the North American coast to Bermuda. From measurements of temperature and salinity, made in a vertical section of the ocean, it is possible to construct the field of density; by virtue of the laws of hydrostatics, the pressure field may then be computed. As in the atmosphere, large-scale horizontal pressure gradients in the ocean are largely balanced by Coriolis forces associated with components of the velocity field normal to them. Oceanographers make frequent use of this so-called 'geostrophic approximation' to calculate the velocity field from the density field because of the great difficulty of making direct current measurements in the sea. It was hoped that frequent hydrographic sections would reveal seasonal fluctuations in the transport of the Gulf Stream system—all of which passes between the North American mainland and Bermuda.

The second part of this programme was to be carried on from the Bermuda Biological Station, using a small vessel provided by a grant of the Royal Society. Because of the peculiar location of the Island of Bermuda, at the centre of the North Atlantic circulation, it was hoped that frequent measurements of the vertical density structure near the Island could be correlated with the transport fluctuations of the Gulf Stream. Should this prove

to be the case, such simple local measurements might eventually be of the very greatest importance for European meteorology and for fisheries hydrography. In any event, it was felt that this phenomenon ought to be explored. It was also proposed that this small vessel, based at Bermuda, should undertake a programme of measurement of wind-drift currents, in order to check the Ekman wind-drift current theory.

Within a year these plans were hopelessly disrupted by the Second World War. However, Iselin² was able to publish in 1940 a preliminary study of thirteen *Atlantis* sections made up to that time. Of course, the number of these sections is very small for the purpose of analysis for periods. Moreover, there are gaps in the series: two sections are available for 1937; five during May–October 1938; and six during May 1939–January 1940. With the latter exception, there are no winter-time observations, a fact which was inevitable because of the relatively small size of the *Atlantis*. Iselin showed what may be interpreted as a seasonal variation in the transport of the Gulf Stream, the most pronounced feature of which is a distinct minimum during October–November. This seasonal variation was supported by tide gauge observations obtained at Charleston and Miami (it is to be expected that changes in the field of density in the ocean will be accompanied by changes in the mean elevation of the sea surface); therefore, it seemed likely that the transport of the Gulf Stream varies seasonally from a minimum transport of at most 76 million, to a maximum of at least 98 million, cubic metres per second.

During the war years, no study of the Gulf Stream system was made. However, an instrument of great practical importance, the bathythermograph, was

Fig. 1. Fugister and Worthington's chart of the mean temperature (°F.) in the upper 200 metres of the Gulf Stream on June 8, 1950, showing the meander-pattern. The solid zig-zag line is the ship's track. The small arrows show the direction of flow (but not speed) as indicated by towed electrodes. The very large horizontal gradient of temperature shown by the crowding of isotherms is along the left side of the Stream. The main body of the Gulf Stream is limited to a band extending not more than 1° of latitude to the south of these intense thermal gradients. In the course of two weeks this meander-pattern was observed to progress about one-half wave-length to the east.

Fig. 2. Mean temperature ($^{\circ}\text{F.}$) of the upper 200 m. layer on June 17, 1950. Current arrows from the 'G.H.E.'. Confirmation to the east of the meanders shown in Fig. 1. It portrays one stage in the development of the unstable breaking up of a meander-pattern in which a large mass of cold northern water is becoming isolated in the warmer surface waters to the south of the Gulf Stream.

devised for the rapid measurement of temperature as a function of depth (900 ft. is the practical maximum depth, at present) from a ship under way. In the North Atlantic Ocean, 210,000 bathythermograph soundings have now accumulated. This useful instrument has also revealed extraordinary horizontal eddy and meander formations along the Gulf Stream, complications which were not previously expected, and which throw some doubt on the validity of the 'geostrophic approximation' for transport calculations because of the small radius of curvature exhibited by some of these features. It therefore seemed possible that the Gulf Stream traverses made by Iselin might have been through meanders, and that the resulting errors in computed transports could have been as large as the variations he attributed to seasonal influences. More recent evidence (referred to later), however, supports Iselin's original interpretation despite the uncertainty of the location of the *Atlantic* traverses relative to meanders. Although it would be very desirable to evaluate directly the various terms in the dynamical equations for even a single meander, by measuring density and velocity over a small network of stations at intervals of a day for a period of several weeks, such a programme is quite beyond the resources of oceanographical science at present.

The exploration of meander-patterns reached a high point in the multiple-ship survey of 1950³, during which seven vessels of the U.S. and Canadian Navies, as well as research institutions, were engaged for more than two weeks in producing a synoptic

chart of a segment of the Gulf Stream eight hundred miles long. The chief result of this effort was to show the existence of a series of horizontal wave patterns beginning at Cape Hatteras and extending downstream to long. 65° W., with a wave-length of approximately 200 km., and a downstream phase-velocity of 11 miles a day (the water in the centre of the Stream moves with a particle velocity of 100 miles a day). At long. 61° W., a meander-wave of excessive amplitude was observed as it developed into a detached eddy of cold water in the warmer water on the offshore side of the Stream. The growth of this single large eddy is interesting because it is the only direct observational evidence of large-scale lateral mixing processes so often postulated in theoretical studies of the dynamics of oceanic circulation.

The introduction of towed electrodes⁴ has proved very useful in such synoptic surveys; although a way for deducing the total transport of the Stream from towed electrode measurements is known on theoretical grounds, it has not yet proved possible to do so for practical reasons. The great practical advantage of towed electrodes is that they provide an instantaneous estimate of surface current from a ship under way; thus the oceanographer knows at every moment which way to direct his vessel to stay with the Stream or to cross it.

Another instrument, the airborne radiation thermometer, has made possible the rapid aerial mapping of meander-patterns by means of their surface temperature. Used from a low-flying aeroplane, this

instrument consists of an infra-red detector which is exposed alternately to the radiation from the sea surface and that from a reference body within the aeroplane. The temperature of the reference body is adjusted so as to produce the same signal upon the detector as does the sea surface; their temperatures thereupon are nearly equal. The inshore edge of the Gulf Stream has been traced all the way from Miami to south of the Grand Banks by this means, in the space of two days.

In the years immediately following the Second World War, there was also a reawakened interest in theoretical study of general oceanic circulation. In a study of the detailed weak horizontal flow patterns in central oceanic areas (excluding strong currents like the Gulf Stream), Sverdrup discovered that they could be accounted for as a balance between the tendency for water moving along meridians to take on a relative vorticity about the local vertical, and the curl of the local wind stress. In another study, Stommel discovered that the east-west asymmetry of oceanic circulations could be explained in terms of the variation of the Coriolis parameter with latitude. In 1950 Munk¹ published an elegant synthesis of these studies in which he was able to deduce the main features of the horizontal transport in the ocean from the actual distribution of the wind stress. Briefly stated in qualitative terms, Munk's theory asserts that the stationary mean-vorticity field of the North Atlantic surface circulation is maintained by a balance of three processes tending to change the vorticity at any point: (1) the local curl of the mean wind stress, (2) the change of relative vorticity due to north-south components of motion (variable Coriolis parameter), and (3) lateral diffusion of vorticity by macro-turbulence. Over most of the North Atlantic the curl of the mean wind stress has the same sign, and since horizontal velocity gradients are too small to make process (3) important, process (2) must provide the necessary balance, and the meridional component of transport hence of same sign (southward). Conservation of mass requires provision for this water to be returned northward; the mathematical solution of the vorticity equation provides such a northward flow in an intense narrow high-velocity 'boundary layer' along the western coast of the ocean where processes (2) and (3) completely dominate process (1). This theoretical concept of a western 'boundary layer' corresponds to the Gulf Stream system. Comparison of the amounts of water transported by such a theoretical Gulf Stream with those measured is encouraging. The chief difficulty in reconciling this theory with the actual Gulf Stream is to discover lateral mixing processes in the Stream sufficient to transfer the vorticity required. Except in the large eddies at long. 61° W., the water in the Stream seems remarkably immiscible with its environment.

Tide gauge observations have gradually been accumulated from gauges recently established at Cat Cay, Havana, and Bermuda, a basic source of information which was largely unavailable from these places before the War. In addition, we have new techniques for measuring quantities indicating the strength of the North Atlantic circulation: since August 1952, measurements of electrical potential difference across the Florida Straits have been regularly made on a submarine cable between Key West and Havana. When the tidal components and the short-period variations due to magnetic storms have been eliminated, there remains a potential

difference produced by electromagnetic induction of the sea water moving through the earth's magnetic field, which is proportional to the total transport of water through the Florida Straits. A preliminary analysis of these measurements has confirmed the seasonal variation described by Iselin, and has also revealed very rapid short-period fluctuations in the transport of water of the Florida current—as much as twofold in ten days. At present these latter fluctuations defy explanation.

Within the past year, an Oceanographic Observatory has been established by the Woods Hole Oceanographic Institution at the Bermuda Biological Station for the purpose of making synoptic studies of the north-western Sargasso Sea. Hourly measurements of wind-drift currents in the shallow surface layers are now being made regularly, using wireless telemetering buoys. Resistance thermometers are being installed permanently on a submarine cable to a depth of 1,600 fathoms, in order that a continuous long-term record of the thermal structure in this critical portion of the North Atlantic can be obtained. This Observatory is the first attempt on the part of oceanographers to obtain continuous day-by-day records from the deep ocean.

It may be expected that in the years to come long-term measuring programmes, such as this Bermuda thermometric cable, will play an increasing part in oceanography. They are certainly much more economical than ships.

In conclusion, it should be evident that despite the fact that the complexity of the ocean circulation is considerably greater than supposed sixteen years ago, the number of techniques of observation has increased correspondingly, and there is no reason to despair of achieving an understanding of the North Atlantic circulation.

STRUCTURE OF OPTICALLY ACTIVE COMPOUNDS IN THE SOLID STATE*

By PROF. J. M. BIJVOET
University of Utrecht

IN the great successes of X-ray analysis that determined structures as complicated as those of sterols and alkaloids and that now ambitiously approach the domain of Nature's most complicated biochemical compounds, the proteins, the central problem of X-ray analysis, namely, the location of the atoms in the crystal, was solved by Fourier methods.

As early as 1915, Sir William Bragg introduced the underlying conception of the crystal¹. Instead of the atomic positions, the electron density all over the crystal is considered, in which distribution the atoms finally reveal themselves. This periodic electron distribution may be developed in a Fourier series, that is, it may be seen as a homogeneous background that is modulated by the superposition of density

* Substance of a course of three lectures delivered in the University of London on March 15, 17 and 19.

Fig. 1. Relation between density waves and X-ray diagram

waves. As these waves must satisfy the periodicity of the crystal, the Fourier development is restricted to a discrete series.

Each density wave causes a reflexion spot on the X-ray diagram, which consequently gives us information about the wave (see Fig. 1). This close relation between X-ray diagram and density waves makes this conception of the crystal eminently useful in X-ray analysis. The position of the diffraction spot gives us the orientation and period of the density wave; its intensity gives the amplitude. The phase of a density wave—that is, the distance of its maximum from the origin of the cell—is lost in the X-ray diagram, however, direction as well as intensity of the reflexion being insensitive to a parallel shift of the reflecting wave front. This lack of information about the phase prohibits the direct synthesis of the Fourier waves, which otherwise would immediately reveal the atomic arrangement from the X-ray diagram. The determination of the phases of the density waves thus constitutes the central problem in the Fourier method of X-ray analysis.

The crystal can be described in either of two ways: by the position of the atoms, or by its Fourier waves. Nature gives us part of either description: the atoms that are present, but not their co-ordinates; she gives the density waves, but not their phases. The problem is to translate either of these complementary sets of data into the language of the other description, thus attaining a description which is complete.

The method that starts on the basis of Fourier waves owes its prevalence to the fact that in Fourier synthesis general methods could be devised for determining phases systematically.

We propose to consider here the heavy-atom technique of phase determination in the form of the isomorphous substitution method. In this method two isomorphous crystals are used. These derivatives have exactly the same crystal structure except for the substitution of one of the atoms by a heavier atom of approximately the same size. From the resulting changes in intensity the unknown phases can be derived. In particular, I propose to extend the common scheme of this method to the non-centrosymmetrical case. Obviously in this case the location of the density waves is more difficult than when a centre is present, since a centre, by reason of symmetry, from the very onset restricts the

possible locations to the extreme cases of maximum or minimum in the origin (centre).

The complete determination of the phases in the non-centrosymmetrical case implies the solution of the old problem of the determination of the absolute configuration of optically active compounds, a problem which chemistry studying the mutual behaviour of compounds cannot solve.

Let us outline the procedure of the isomorphous substitution method in this general case. Though the structure of the crystal is not known, the configuration of the heavy atom, which strongly influences the intensities, can easily be determined by a special procedure, the Patterson synthesis, and we shall consider it here as known. By the isomorphous substitution an extra electron density corresponding to the latter configuration is introduced. We shall call this known density the 'test density', because it will be used to test the location of the component waves. Added to the light compound, it yields the density of the heavy compound (see Fig. 2, left-hand column). If we represent each of these three electron densities by its Fourier waves, the sum relation will also hold for every set of the component Fourier waves (Fig. 2). It is this additivity relation which permits the determination of the phase angles—though only in absolute value. For in each set the test wave is known in amplitude and phase, whereas the amplitudes alone of the other two terms are known from the X-ray diagrams. In the addition process, only the correct phase of the light-compound wave will yield the observed amplitude of the heavy-compound wave. The unknown phases can thus be calculated from the three known amplitudes.

It is interesting to note that this problem ofatching phase differences by turning them into amplitude differences is by no means restricted to X-ray analysis. It also turns up in, for example, microscopy. When the object is perfectly trans-

Fig. 2. Additivity relation between electron densities of light- and heavy-atom compounds and their Fourier waves respectively

Fig. 3. Determination of phase sign by anomalous scattering

parent, there are only phase differences in the image, which consequently cannot be seen. In intercepting the undeviated light, a constant vector is subtracted in every point of the image, and vectors of different amplitude result.

The amplitude or intensity comparison of light and heavy compound upon which phase determination is based is widely used in the centrosymmetrical case. Since the famous example of phthalocyanine³, a number of centrosymmetrical projections of complicated compounds have been determined along these lines. It is fortunate for the easy applicability of the method that most biochemical substances crystallize in space groups with a two-fold axis, so that we have at least one centrosymmetrical projection. For the non-centrosymmetrical projections the determination of the phase angle obviously needs more accurate intensity data, but careful intensity measurements appear to give the phase angles with sufficient accuracy, as has been proved in the cases of strychnine hydrosulphate/selenate³ and glycyltyrosine hydrochloride/bromide⁴. However, in the location of the waves, a last and rather serious difficulty still remains. When we determine the relative location of the Fourier wave and the test wave, it remains undecided whether the Fourier wave at the required distance is on one side or on the other side of the test wave (see Fig. 3). It is the *sign* of the phase angle that is unknown and still prevents the direct synthesis. So we find ourselves confronted with the problem of the determination of sign of the phase angle, a rather puzzling problem that has no counterpart in the centrosymmetrical case. This problem can be solved by a trick⁵.

We take a Fourier wave *A* of the heavy atom configuration and the corresponding wave *B* of the rest of the crystal. For ordinary X-rays it is the path difference only between *A* and *B* which causes the phase differences between their diffracted beams, and $\varphi_B - \varphi_A = (\varphi_B - \varphi_A)_{\text{path}}$.

This is equal—though of opposite sign—in our two cases (Fig. 3) and as a consequence these cases cannot be distinguished, as the resulting intensities are equal.

If, however, we use X-rays of special wave-length, which just excite the heavy atoms, the X-rays will be absorbed as well as scattered by this atom in an anomalous way. It is this anomalous scattering which is made use of in distinguishing the two cases of Fig. 3.

All electrons scatter like free electrons if the frequency of the incident radiation is large compared with their own frequency. The strongly bound K-electrons of the heavy atoms, on the other hand, oscillate and scatter with phase opposite to that of the free electrons. Going from hard to soft X-rays, the K-electrons change their behaviour in the region where the frequency of the incident radiation approaches the proper frequencies of these K-electrons: the phase changes gradually when approaching the absorption limit.

Under these conditions:

$$\varphi_B - \varphi_A = (\varphi_B - \varphi_A)_{\text{path}} + (\varphi_B - \varphi_A)_{\text{primary scattering}}$$

in which only the first term on the right-hand side changes sign for the two situations of Fig. 3. The total difference is seen to take different values, which enables us to distinguish the two situations. The influence of anomalous scattering on the reflexion intensity of a density wave thus makes the determination of the sign of its phase angle possible.

In our microscope example, the different phases in the image were turned into different amplitudes by the interception of the undeviated light. However, phases which are mutually opposite in respect to the intercepted component in this optical case also remain indistinguishable. In the phase-contrast microscope⁶, this is remedied by imparting to this component an abnormal phase change instead of intercepting it.

Thus the phase problem in X-ray analysis, that is, the determination of phase angles also in sign, is solved. Theoretically, Fourier synthesis is then straightforward also in the non-centrosymmetrical case, and this synthesis gives the antipode in its absolute configuration since the inversed image has opposite phase-angle signs.

The chart opposite summarizes the whole procedure for different cases of complexity. In the direct synthesis of non-centrosymmetrical structures, there is a gap between what is theoretically possible and what has actually been achieved hitherto. The note of interrogation indicating this gap refers to practical difficulties. It has not yet been thoroughly investigated whether the small effect of the anomalous scattering will be measurable for a sufficient part of the reflexions involved in a complete Fourier synthesis. There is every appearance, however, that the increasing accuracy of the measuring technique will indeed enable us to realize this programme.

An alternative method, which lacks the straightforwardness of the direct method, consists of the determination of the combination of relative phase signs and the subsequent absolute determination of a single one of them.

In the first part of this procedure, which has been followed for strychnine hydrosulphate/selenate and glycyltyrosine hydrochloride/bromide, a Fourier synthesis is made with the double number of waves, both signs of the phase angle being used simultaneously. This double Fourier will give the super-

PHASE DETERMINATION IN THE ISOMORPHOUS SUBSTITUTION METHOD

(d) Phase shift by anomalous scattering (1980).
Determination of absolute configuration (1961).
(e) Determination of all phase signs by anomalous scattering (1971).

position of the two antipodes, as the right set of signs results in the actual structure of the opposite set in the inverted structure. These two structures must be separated by geometrical considerations, which require the interatomic distances to be of normal value. These spatial considerations deprive the method of much of its simplicity and beauty; the atoms no longer 'emerge' quite spontaneously from the X-ray data which is so striking in direct Fourier synthesis. It is therefore obvious that along these lines no discrimination is reached between the two disentangled structures. The double Fourier was used for the first time under somewhat different conditions in the structure determination of cholesterol hydride⁷, and later on, in the form just described, in the cases of strychnine sulphate/selenate and glycyltyrosine hydrochloride/bromide.

The second part of the procedure consists of the decision between the two models after the structure has been found, except for possible inversion. This determination of absolute configuration has been carried out for a compound basic⁸ in stereochemistry: for tartaric acid, in the form of the sodium rubidium double salt⁹ and the acid rubidium salt¹⁰.

Anomalous scattering of the rubidium atoms was obtained by the use of x-ray rays. Although the phase sign of one density wave would have been sufficient, the effect was observed for several reflexions. The phase signs of the salts of dextro-rotatory tartaric acid fitted the conventional model, which consequently was proved to correspond to its real configuration.

As early as 1930, Coster proved the III and III' reflexions of zinc sulphide are of unequal intensities for rays exciting the zinc atom. This determination of the sense of a sequence is exactly the problem we met with in the location of our reference wave and the Fourier wave of our crystal. In both cases it is the sense of a polar sequence which must be determined, and indeed can be determined by anomalous diffraction.

The method for determining absolute configuration supplies organic chemistry with a means of establishing the configurational relation between compounds which cannot be converted into each other, or in the conversion of which a Walden inversion may take place that changes the configuration into its mirror image. Investigations in this field are in progress in several laboratories.

It is surprising that, although the structure effect in zinc sulphide was known, the determination of absolute configuration was still thought for many years to be impossible.

THE QUEEN'S UNIVERSITY,
BELFAST

NEW GEOLOGY BUILDING

WHEN Queen's College, Belfast, was founded in 1847, Frederick McCoy was appointed to the chair of geology and mineralogy. In 1854 McCoy left Belfast for Australia, where he continued to build up his world reputation as a palaeontologist and was eventually knighted. Wyville-Thompson, who succeeded him, became professor of natural history in 1860 on the amalgamation of his own Department with the Departments of Zoology and Botany. After Wyville-Thompson went to Edinburgh in 1870 and until 1909, geology continued to be taught in the combined Department. With the foundation of The Queen's University in 1909, chairs of zoology and botany and a lectureship in geology were created, Dr. A. R. Derryhouse being elected to the new lectureship. On his resignation in 1921, the chair of geology was re-established, and Dr. J. K. Charlesworth was appointed.

In the days of Queen's College, geology shared a common museum and lecture room. Since 1921 the Department has occupied a succession of wooden buildings, at first two army huts, later the orthopaedic and later still some of the general wards of the Ulster Volunteer Force Hospital erected in the grounds of the University in 1915. Plans were prepared in the 1930's for a new geology building, with Mr. John McGeagh as architect and Mr. (now Sir) Edward Maufe, R.A., as consultant. The outbreak of war in 1939 and the subsequent shortage of materials postponed the erection of the building until September 1950 and its completion until this year. The formal opening by Sir Edward Bailey took place on April 30.

The geology building forms the south-west wing of a group of buildings to be arranged around a large quadrangle opening to the south on to Elmwood Avenue. Hence the entrance to the geology building

The Queen's University, Belfast. New geology building

Belfast News-Letter

is on the north at one end of a future cloister. The exterior has been designed on clean contemporary lines and has regard for the adjacent agricultural building of Georgian style and for the traditional styles of the University district. The chief materials are Buckley Junction hand-made sand-faced bricks, Oliphame stone and green Borrowdale slates.

The building, rectangular in plan, is about 124 ft. long and 41-44 ft. wide. It has three floors, an attic, and a basement or lower ground floor. The latter, which is excavated beneath the whole site except the lecture theatre, is occupied by women's and men's cloak rooms and lavatories; by a boiler house with solid fuel fed by automatic stoking thermally controlled, and designed ultimately to heat half the buildings around the new quadrangle; by an unpacking room which receives large consignments of rocks or apparatus by a ramp from the gate leading to the agricultural court; and by a rock-cutting room the ceiling of which is cork-insulated to eliminate vibration and sound from the rest of the building. A full-sized lift carries the loads to each floor, including the attic.

On the ground floor are the entrance vestibule, senior laboratory, attendant's room, demonstration lobby, lecture theatre and professor's rooms; on the first floor the elementary laboratory, map room and library, and photographic rooms; and on the second floor the large petrology and palaeontology laboratories, chemical laboratory and small lecture room. Staff and research rooms occur on each floor. The undivided attic, which extends beneath a mansard

roof over one-third of the building, is well lit by circular dome lights of glass in the flat part of the roof and is ventilated by clerestory windows. It provides the research and store space of the future.

The lecture theatre, which seats 160, has mechanical ventilation, electrically operated blinds, dimming roof lights, and a large lecture bench. Uninterrupted views are obtained of the bench, blackboards, coloured geological models, maps and projection screen. The demonstration lobby, on the line of approach to the lecture theatre, serves for the display of photographs, maps and specimens to illustrate lectures and at the same time gives added spaciousness to the entrance hall. The two supporting rectangular columns have been used for depicting the geological column in its chronological, palaeontological, petrological and tectonic aspects.

The corridors, which are 8 ft. wide to provide viewing space for the numerous coloured maps, have been reduced to a minimum by placing the lecture theatre, large laboratories and library and map room at the ends of the building. The laboratories are lined along their outside walls with show-cases which fit flush under the windows and rest on drawers. In this way, a separate museum is avoided, all the material in the Department forms part of the teaching collections, and space is provided for new accessions which are immediately available for study: store-rooms as such become unnecessary. The wall cases have dictated the method of heating throughout the building, which is by low-pressure hot-water panels embedded in the ceilings. J. K. CHARLESWORTH

OBITUARY

Dr. E. M. Crowther

AGRICULTURAL science and particularly soil science have suffered a grievous loss in the sudden death of Edward Mortimer Crowther on March 17 at the comparatively early age of fifty-six.

Born near York on April 15, 1897, he was educated at Archbishop Holgate's School, York, and the University of Leeds, where he read chemistry, specializing in agricultural chemistry in his last year. In 1917 he joined the staff of Rothamsted Experimental Station, and ten years later, when he was only thirty, Sir John Russell, who was then director, recognizing his outstanding ability, made him head of the Chemistry Department, a position he occupied until his death. In 1950 he became one of the two deputy directors of the Station.

Crowther's early work was chiefly on the physics and physical chemistry of soils, and he published a series of important papers on methods of mechanical analysis and on soil reaction. His main interest, however, throughout a very active career, was soil fertility and crop nutrition. While maintaining the great tradition of Lawes and Gilbert, he added to their thoroughness the exactitude of modern methods of field experimentation. Recognizing at once the value of the statistical work of R. A. Fisher and F. Yates on experimental design, he became the pioneer of its application to field experiments in agriculture and forestry, and his influence was felt and his advice sought in many parts of the world.

He became one of the greatest authorities on the use of fertilizers, and as a result of his work, major improvements were made in the manuring of various crops, notably sugar beet, potatoes and flax. He demonstrated conclusively, for example, the manurial value of salt for sugar beet, a matter of importance particularly during the war-time scarcity of potash. His work also threw fresh light on methods of soil analysis, and he used field experiments for improving and calibrating these methods. For many years he had been giving attention to the problems of phosphatic fertilizers, including the immobilization of water-soluble phosphate in soil, and latterly he had been employing radiotracer techniques. This work was a good illustration of his method of using the results of field experiments for developing new lines of work in the laboratory, which in their turn reacted on his field approach. During the Second World War, in collaboration with the Building Research Station, he was actively engaged in the development of a silicophosphate fertilizer, and more recently he had been engaged in assessing the value of this and other new phosphatic fertilizers which are being developed to economize in the use of sulphuric acid. His interest in fertilizers, however, did not cause him to neglect organic manures, and he did much work on farmyard manure, sewage sludge, composts and green manuring, endeavouring to assess their manurial value and long-term effects.

During the War he was deeply involved in questions of fertilizer policy. There were difficult decisions to be taken regarding the use of shipping for the importation of fertilizers or food, and the problems of using the limited quantities of fertilizers in those parts of Great Britain which needed them most. With F. Yates he made a survey and critical analysis of all fertilizer experiments in Great Britain and other northern European countries, and the success-

ful rationing policy was largely the application of his work and of his unrivalled knowledge of crop nutrition. He rightly advocated the use of much greater amounts of nitrogen, and the rapid increase in food production was in no small measure due to this. The Ministry of Agriculture frequently sought his advice and made use of his services on many of its committees.

In recent years Crowther became keenly interested in the manuring of forest nurseries and in the rehabilitation by means of 'partial sterilization' of some of the old nurseries which had ceased to raise useful conifer seedlings. He showed that, in general, properly balanced fertilizers are as effective as composts for this purpose, and revolutionized the manuring practice in the Forestry Commission's nurseries.

Crowther's interests were by no means confined to British agriculture. He travelled widely, visiting many parts of Europe, America, Africa, India and Malaya, and those of us who accompanied him on some of these journeys will always recall his tireless energy, his penetrating observation, and his breadth of outlook. It was natural that his early interest in soil classification and particularly in the relation between soil and climate should be intensified by these travels.

Most of his work in the tropics, however, was connected with soil fertility problems, and he planned and supervised many manurial experiments on cotton, oil palm and rubber. He had a special interest in the Sudan, where he collaborated with his brother, the late Dr. Frank Crowther, and he served for many years on the Sudan Government London Advisory Committee and on the Research Advisory Committee of the Empire Cotton Growing Corporation. The Colonial Office made much use of his wide knowledge, and he was a valued member of the Committee for Colonial Agricultural and Animal Health and Forestry Research.

His capacity for blending academic research with the investigation of practical problems is well illustrated in his publications, the wide range of subjects of which indicate the variety of his interests. He was one of the editors of the *Journal of Agricultural Science* and the *Empire Journal of Experimental Agriculture*, and was active in many scientific societies, including the International Society of Soil Science. In 1951 he was president of Section M (Agriculture) of the British Association, and in 1952 and 1953 of the British Society of Soil Science and the Fertilizer Society. Both as a writer and speaker he was lucid and effective, and he completed the Jubilee Memorial Lectures of the Society of Chemical Industry only a few days before he died.

Among the qualities associated with Crowther in the memory of those who were privileged to know him, his sincerity, integrity and kindness stand out. The most loyal of colleagues, he would take great trouble to advise and assist the serious worker, however junior; but he had a keen critical faculty and was not slow to expose what was superficial and slipshod. In him, world agronomy has lost one of its foremost workers, and the deep personal affection and professional esteem in which he was widely held have been strikingly shown by the messages received since his death.

He married Miss Elizabeth Dorothy Kay in 1924, and she and their son survive him.

W. G. Ogg

NEWS and VIEWS

Agricultural Botany at Reading:

Prof. W. B. Brierley

PROF. WILLIAM B. BRIERLEY, who retires from the chair of agricultural botany in the University of Reading in September, was educated at the University of Manchester and in 1912 was appointed to the staff of the Department of Botany there. In 1916 he went to Kew as joint head of the newly established Pathological Laboratory, and in 1918 to Rothamsted as the first head of the Department of Plant Pathology which, during his period, developed from a small, bare room into a notable centre of plant disease research. In 1932 he succeeded Prof. John Percival at Reading. His personal investigations have been in the fields of phytopathology and microbiology, where his interests and guiding influence have made themselves felt throughout the world: his paper on an albino *Botrytis* in the *Transactions of the Royal Society* is a classic. In Reading he has built up an honours school in the sciences that together constitute the field of agricultural botany, which has sent research workers and teachers to all parts of the world. For a quarter of a century Brierley was honorary editor of the *Annals of Applied Biology*, a task which he carried out with unremitting care and scientific integrity. He is an honorary member of the Association of Applied Biologists and a freeman of the American Phytopathological Society. A welcome visitor to European and American centres of botanical research, and a prolific correspondent, his contacts in many lands have given him a world-wide reputation in the field of applied botany.

Prof. D. W. Goodall

DR. DAVID W. GOODALL, reader in botany in the University College of the Gold Coast, who succeeds Prof. Brierley, graduated at the Imperial College of Science and Technology, London, and worked for some years under Prof. F. G. Gregory on problems of plant development and nutrition. In collaboration with Prof. Gregory he published a valuable book on the chemical composition of plants as an index of their nutritional status. For two years he was in the Colonial Agricultural Service, seconded to the West African Cocoa Research Institute, where he worked on physiological problems in the cacao plant. In 1948 he was appointed senior lecturer in botany in the University of Melbourne, where he became especially interested in statistical ecology, and he has developed this interest further in relation to the classification of types of tropical vegetation since his return to the Gold Coast.

National Research Council of Canada:

Mr. B. G. Ballard, O.B.E.

MR. B. G. BALLARD, director of the Division of Radio and Electrical Engineering of the National Research Council of Canada, has been appointed to the additional post of vice-president (scientific), in succession to Dr. E. W. R. Steacie, the present president of the Council (see *Nature*, 169, 1049; 1952). Mr. Ballard graduated in 1924 from Queen's University, Kingston, Ontario, and afterwards was on the Westinghouse staff for five years working on the development of railway electrification. He was appointed to the Division of Physics of the National Research Council in 1930, and during the following ten years he gradually built up the Electrical

Engineering Section. This work became extremely important during the Second World War, when Mr. Ballard's efforts included the development of mine-sweepers and other means of protecting ships against enemy magnetic mines. The equipment was used on both coasts as well as on the high seas, and his work was recognized by the award of the O.B.E. In 1946 the Electrical Engineering Section was amalgamated with the Radio Branch of the Division of Physics and Electrical Engineering, and Mr. Ballard was made assistant director of the Division. With the subsequent expansion of work a separate Division of Radio and Electrical Engineering was established in 1948, and Mr. Ballard was appointed its director. In 1949 he was awarded the Ross Medal of the Engineering Institute of Canada for a publication called "Recent Canadian Radar".

Sir Jack Drummond Memorial Fund

THOUGH the raising of funds for a fellowship in memory of the late Sir Jack Drummond has not yet been terminated, sufficient money has already been accumulated for an award to be made available as from October 1. The fellowship will be worth £900 a year, tenable in the first instance for one year, and will be for research on nutrition, with special emphasis on human nutrition, to be conducted in, or in association with, a university department or research institute of similar standing. The award may be made to a comparatively young scientific worker provided he has reached a stage at which he can undertake independent work. Further information can be obtained from Dr. B. Ifor Evans, Provost of University College, Gower Street, London, W.C.1.

New Building for the Radio Research Station

ON May 10, Dr. R. L. Smith-Rose, director of radio research in the Department of Scientific and Industrial Research, cut the first sod on the site of a new building being erected at the Radio Research Station, Ditton Park, Slough. This occasion marks another step in the Department's post-war plan for a considerable extension in the programme of research conducted under the advice of the Radio Research Board. The site is in the grounds of the Admiralty Compass Observatory at Ditton Park, where nearly 100 acres have been available for field experimental work for many years past. In addition, the Ministry of Works has purchased another 100 acres of the neighbouring farm. This additional land has been acquired mainly to ensure that the whole site is kept free from undesirable electrical interference with the radio research work. A very small portion of it may be used for further experimental work; but apart from this, the additional land will continue to be available to the farmer. The building has been designed by the architects of the Ministry of Works specifically to meet the requirements of the Radio Research Station. A two-story administrative block together with the workshops, stores, dining-room and all general services are concentrated at one end of the building. The scientific and technical laboratories are contained in a single-story building with a main block and four spurs, the ends of which open directly on to the field, which is regarded, for radio experiments, as a continuation of the laboratory working-space. Every effort is being made to restrict the metalwork installed in the field so that the minimum of disturbance is caused to experimental work. In order to reduce to the minimum the radio interference from the ignition systems of motor traffic,

the building site is more than 200 yards from the nearest road; and most of the working parts of the fields in use are nearly half a mile from any public road carrying vehicular traffic. In cases where the research work is of a type that cannot be conducted inside the building, provision is made for the use of a number of huts of a temporary and transportable nature. The present staff of the Radio Research Station, all in temporary accommodation, is just over a hundred, and it is expected that this will be considerably increased when the new building is ready for occupation.

Metallic Corrosion: an Instructional Film

A 16-mm. coloured film entitled "Corrosion in Action", originally made in the United States under the auspices of the International Nickel Company, Inc., is now available in Britain and can be borrowed for educational or other purposes from the Mond Nickel Company, Ltd. (Thames House, Millbank, London, S.W.1). The film, which lasts for sixty-four minutes, has to a certain extent been edited for British consumption, the main change being a new sound-track with an English-accent commentary. Each topic begins from first principles but rapidly builds up to intermediate and even degree level. The economic importance of the general corrosion of metals is first explained, and then a short historical survey leads to a diagrammatic explanation of electro-chemical corrosion, oxygen being emphasized as a promoter of cathodic reactions. The arrangements of metals in their electromotive series introduce a discussion of galvanic action in terms of potentials, current density and area effects, and this is shown in a series of laboratory tests utilizing colour-changing reagents which detect the existence of anodic and cathodic corrosion products. Passivity and protective films are demonstrated by a series of bench experiments, indicating how important the film can be in some instances. Local shielding and the damage resulting from it are followed by a section comparing the mechanism of corrosion of various materials. The film ends with illustrations of the measures that can be taken to minimize corrosion and the importance of choosing materials in the light of the full knowledge of the many factors in individual corrosion problems.

Agricultural History Review

WITHIN a year of its inauguration, the British Agricultural History Society has issued the first volume of its official publication, the *Agricultural History Review*. The Society was founded to bring together those interested in agriculture as a living, historical process, whether their sphere of activity lay in academic institutions or in the countryside. The new publication should do much to promote this aim, and its appearance is timely in view of the rapid changes that have been taking place in rural life and practice during the mid-twentieth century. Each issue will contain a number of articles embodying original research in agricultural history, together with shorter notes and comments, a bibliography and book reviews. The following titles of the articles in the first number, each of which is contributed by a well-known specialist, give some idea of the scope of the publication and the potential wealth of suitable subject-matter: some traditional farming beliefs in the light of modern science; the poll tax and census of sheep, 1549; the Isle of Axholme before Vermuyden; agricultural returns and the government

during the Napoleonic Wars; a Cornish farmer in Ontario, 1830-71. The *Review* is issued only to members of the Society (c/o Museum of English Rural Life, 7 Shinfield Road, Reading; 1 guinea a year). The first number contains sixty-four pages, and at least two issues annually are anticipated.

Bird Study

As in every other science, progress in ornithology is very dependent upon publication. This point is well brought out by Major-General H. P. W. Hutson, chairman of the British Trust for Ornithology, in the foreword to a new journal which has recently been launched by the Trust (*Bird Study*, 1, No. 1; March 1954). The first issue contains an article by J. F. Monk on the breeding of the greenfinch and another by D. Lack describing observations made on robin populations in Oxford and south Devon. The Rev. P. H. T. Hartley has contributed a stimulating and unusual article on back-garden ornithology which should be most encouraging to would-be bird observers. The journal also contains a section illustrating recent activities of the British Trust for Ornithology. The production of this journal is of good standard, although one misses the attractive photographs which have become a marked feature of other bird journals.

Institution of Mining and Metallurgy: Awards

THE Institution of Mining and Metallurgy has recently made the following awards: *Gold Medal of the Institution*, to Mr. Essington Lewis, president of the Fifth Empire Mining and Metallurgical Congress, in recognition of his long and distinguished services to the mining and metallurgical industries of Australia; *The Consolidated Gold Fields of South Africa, Limited, Gold Medal*, to Dr. J. S. Webb, for his work on the development of geochemical prospecting methods; *The Consolidated Gold Fields of South Africa, Limited, Premium of Forty Guineas*, to Mr. R. Daniel, for his paper on diamond mining practice in Kimberley, South Africa (*Trans.*, 62); *Arthur Cloude Student's Prize*, to Mr. T. A. Henderson, for his part authorship of the paper on some exploratory experiments on the formation and control of magnetite during copper smelting operations (*Trans.*, 62); *William Frocheville Student's Prize*, to Mr. C. L. Hall, for his part authorship of the paper on laboratory tests on the concentration of witherite from the northern Pennines by froth flotation (*Trans.*, 62). Honorary membership of the Institution has been conferred on Mr. Thomas Pryor, past-president of the Institution, in recognition of his services to the Institution and to mining education.

Nuclear Physics Conference in Glasgow

AN international conference on experimental and theoretical nuclear physics will be held in the Department of Natural Philosophy of the University of Glasgow during July 12-17, under the general chairmanship of Prof. P. I. Dee. This conference is sponsored by the International Union of Pure and Applied Physics and the United Nations Educational, Scientific and Cultural Organization, and is one of similar conferences on various topics which are held each year in a country of the United Nations Organization. It is fitting that Glasgow should be chosen as the meeting place, as this year has seen the opening of the new Nuclear Physics Building, housing, among other apparatus, the largest synchrotron in Europe. There will be about three

hundred delegates to the conference, representing twenty-six different countries. During the conference lectures will be given on the outstanding problems of nuclear science, with particular reference to the part played by mesons in nuclear forces, and it is hoped that the interchange of information and ideas between physicists from different parts of the world will result in some of these problems being solved. Further information can be obtained from the secretary of the conference, Dr. K. G. McNeill, Department of Natural Philosophy, University, Glasgow, W.2.

Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: G. W. Anderson (agricultural officer, Zanzibar), agricultural officer, Uganda; R. N. Coster (agricultural officer, Fiji), agricultural officer, Sierra Leone; M. Luman (agricultural officer, Tanganyika), regional assistant director of agriculture, Tanganyika; R. K. Tremlett (agricultural officer, Uganda), agricultural officer, Zanzibar; N. Kirby (deputy government chemist, Jamaica), government chemist, Jamaica; E. W. March (conservator of forests, Jamaica), conservator of forests, Nigeria; J. D. Arneed (medical officer, grade B, Trinidad), pathologist, grade B, Trinidad; W. R. E. Nanton (agricultural officer, Grenada), superintendent of agriculture, Windward Islands; B. C. Akhurst and H. W. Mitchell, agricultural officers, Tanganyika; J. R. Watkins, geologist, Uganda; Miss M. M. Bools, pathologist, Sierra Leone; Miss H. T. Brash, soil survey officer, Gold Coast; A. E. Green, senior British laboratory technician, Rockefeller Foundation Regional Virus Laboratory, Trinidad; D. P. Hinton, agricultural officer, Northern Rhodesia; H. W. Ord, economist/statistician, Kenya.

Announcements

PROF. B. F. J. SCHONLAND, director of the Bernard Price Institute of Geophysics and Carnegie-Price professor of geophysics in the University of the Witwatersrand, has been appointed deputy director of the Atomic Energy Research Establishment, Harwell.

DR. D. B. SPALDING, University demonstrator in engineering in the University of Cambridge, has been appointed to the University of London readership in applied heat tenable at the Imperial College of Science and Technology.

A RESEARCH scholarship worth £400 a year for two years has been offered by the Aluminium Development Association to encourage and facilitate research in the application of light alloys to ship construction. The scholarship will be administered by a committee of the Institution of Naval Architects, and it is hoped to make an award in September this year. Further particulars of entry, which closes on June 30, can be obtained from the Secretary of the Institution, 10 Upper Belgrave Street, London, S.W.1.

THE Bermuda Biological Station has recently received a grant covering a period of five years from the United States National Science Foundation. These funds, which are immediately available, will be awarded mainly as fellowships to pay for research space, living expenses or special collecting facilities required while at the Station; applications for aid in purchasing equipment or necessary travel expenses may also be considered. A booklet describing the

Bermuda Biological Station, and application forms for the fellowships, can be obtained from the director, Dr. William H. Sutcliffe, jun., Bermuda Biological Station, St. George's West, Bermuda.

THE centenary of the birth of Henri Poincaré, mathematician and philosopher, will be celebrated in Paris during May 15-17. Further ceremonies will be held in Nancy on May 22 and later in Caen. Further information can be obtained from Le Comité d'organisation du Centenaire, Amis de l'École Polytechnique, 17 rue Descartes, Paris 5^e.

THE Meteorologische Gesellschaft in Hamburg will be holding a meeting in Hamburg during October 4-6 in honour of the centenary of the birth of G. Hellmann. Papers not longer than fifteen minutes in duration will be read, and such contributions must be submitted (with a short summary) not later than July 1 to the Meteorologische Gesellschaft, Bernhard-Nocht-Strasse 76, Hamburg 4, from which further information can be obtained.

THE Institute of Chemistry of Ireland is holding a summer school in organic chemistry in University College, Dublin, during July 6-9. Four lectures will be given on the fundamentals of the subject and two lectures on each of the following: newer methods and reagents; electrophoresis; analysis; distillation; chromatography; and spectrophotometry. The fee for the course is one guinea for members of the Institute and two guineas for non-members (students 10s.). Application forms and further information can be obtained from the Secretary, Institute of Chemistry of Ireland, 18 Ely Place, Dublin.

THE Royal Institute of Chemistry is arranging a symposium on recent advances in the chemistry and industrial applications of cellulose, to be held in the University of St. Andrews during June 28-July 2. The symposium will consider three topics: chemistry of cellulose; paper and pulp; and industrial applications of cellulose and its derivatives. Further information can be obtained from the Assistant Secretary, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1.

A CONFERENCE on soil microbiology will be held at Purdue University during June 21-24, sponsored by the American Society of Agronomy, the Soil Science Society of America, and Purdue University. There will be major sessions on the following topics: physical properties of soils as affected by microbial activities; soil organic matter maintenance; organic matter transformations; and frontiers in soil microbiological research. Further information can be obtained from Lewis W. Erdman, Plant Industry Station, Beltsville, Maryland.

FORTY years ago the first paper dealing with oxide-coated cathodes was published, and to celebrate this anniversary the Société Française des Ingénieurs Techniciens du Vide is organising an international convention to be held in Paris during June 24-26. The programme will be in six parts, dealing with the following topics: metal base; carbonates and coating process; emission theory of oxide-coated cathodes; definition of the cathode properties; special cathodes; and stability of emissive properties. The texts of the papers to be read will be published in a special issue of the journal *Le Vide*. Further information can be obtained from the Société Française des Ingénieurs Techniciens du Vide, 44 rue de Rennes, Paris 6^e.

THE TRAINING OF BIOLOGISTS

A DISCUSSION on the training of biologists, organized by the Institute of Biology, was held in London during April 21-22. The first session, under the chairmanship of Mr. J. F. Wolfenden, vice-chancellor of the University of Reading, was opened by Miss R. Hemmings (Girls' High School, Burton-on-Trent). She stressed the poor background from which the majority of the pupils at maintained schools come, and their ignorance, when they leave the primary schools, of any foreign language or mathematics, and of the principles of clear thinking. These deficiencies make the process of giving them a broad education both slow and difficult, and this in its turn reacts on the teaching of science. The careers which the girls follow vary widely; but teaching is not favoured. Mr. G. B. Hindle (King's Norton Grammar School for Boys) spoke of the great improvements that have taken place during the past twenty-five years in laboratories, text-books and the technique of teaching. This has been accompanied by a big increase in sixth-form numbers, and at King's Norton the use of the science sixth as a school of liberal education is encouraged. Mr. Hindle felt that professional biologists of the experimental type could be made if one started at the sixth-form level or even later, but that the training of field naturalists should begin much earlier. The shortage of qualified staff is an obvious difficulty, and while it was his opinion that pass-degree men were seldom of much use for sixth-form work, they could be helpful in the middle school.

Mr. W. H. Dowdeswell, describing conditions at Winchester College, said that biology is not begun until the sixth-form stage is reached, and this works well, at least with fairly able boys. Much emphasis is placed on field-work, about one-seventh of the total class-time being spent on this. A great handicap in making the subject live is that text-books, although so full of facts that they are difficult to read, do not treat the organisms as living creatures; they describe, for example, an abstract 'earthworm', in apparent ignorance of the fact that there are in Britain about a dozen species of different structure, habits and distribution. Mr. C. Bibby (College of St. Mark and St. John, London) balanced the wide range of initial knowledge of his students, from zero to degree standard, against the great freedom which the training colleges have to arrange their own courses.

The subsequent discussion ranged over a wide field. Points which were made by more than one speaker were that a chief duty of schools is to give a liberal education, and that many teachers keep much too closely to the syllabus and the text-book, in the mistaken belief that that is the only way to get their pupils through examinations. In answer to a question, Dr. G. E. Fogg said that the present over-production of pass-degree and third-class honours men unsuitable for teaching is not so large as had been predicted.

At the next session Dr. R. K. S. Wood (Imperial College of Science and Technology, London) gave a summary of the replies received to a questionnaire recently circulated by the Institute of Biology to heads of university departments. About two-thirds of the botany and zoology departments replied, and in nearly all there is some specialization in the final

year; but while in botany the number in which some choice is given is about the same as that in which all the special courses are compulsory, in the majority of zoology departments the student has some choice. A slight majority of the zoological heads think that this specialization ought to be reduced to a minimum; but nearly all the botanists accept it as inevitable and desirable.

Undergraduate courses in botany, plant physiology and zoology were dealt with by Dr. J. Heslop-Harrison (University College, London), Prof. F. G. Gregory (Imperial College of Science and Technology, London) and Dr. J. A. Kitching (University of Bristol), respectively. All three liked their students to have read chemistry, physics and mathematics instead of biology at school, although Prof. Gregory restricted this preference to those who would become research workers. Dr. Heslop-Harrison asked if it would not be better for future teachers and such-like to read pass degrees, so that all honours students could stay on and do postgraduate work. Prof. Gregory made a plea for the education of biological administrators—an important and increasing class. Dr. Kitching described the course at Bristol, where systematic zoology is compressed into one year and much attention is given to field-work and such special subjects as cytology and embryology.

Prof. J. F. Danielli (King's College, London) spoke on the other biological subjects and described the two ways of teaching biochemistry: as an undergraduate subject to students who have physics, chemistry and mathematics but know no biology, and as a postgraduate course for chemists or biologists. He said that the outstanding problems are the failure of the universities in general education and of the schools to attract outstanding teachers. A partial reason for the second of these was given in the subsequent discussion when Mr. D. A. Sturdy (Felsted School) said that if the universities do not want the schools to teach biology it is unlikely that the schools could attract good teachers. Prof. F. R. Winton (University of London) said that students must be allowed to study a subject when they are interested in it, a view which was applauded, and Dr. Wood that if biology were excluded from the schools there would soon be no biologists. Mr. W. B. Yapp (University of Birmingham) said that the trouble with insisting that future biologists should read chemistry, physics and mathematics in the sixth form is that the Advanced Level syllabuses in these subjects do not contain the material which they need.

The third session dealt with biology in technical colleges. Mr. S. A. Smith (London School of Hygiene and Tropical Medicine) described the courses for the examinations of the City and Guilds Institute and of the Science Technologists Association, and Dr. H. F. Steedman the special courses in biological technology which are run in the University of Glasgow. Both types of course were welcomed by speakers from the floor. Prof. I. A. Preece (Heriot-Watt College, Edinburgh) spoke on the need for a National Certificate in Biology, which would give a more theoretical qualification for such technicians as those responsible for routine testing in factories. Miss J. E. Heriot (Brighton Technical College) spoke on the difficulties and successes of technical colleges in

their degree work. In a lively discussion which followed, there was support for the idea of a National Certificate, and the difficulties in training isolated technicians, including those in schools, were stressed.

The final session dealt with postgraduate training. Summarizing the replies to the Institute's questionnaire, Dr. Wood said that few departments give any special courses in research methods, and that neither in botany nor zoology is it common for there to be concentration of the main resources of a department on a narrow field of inquiry. Dr. G. E. Fogg (University College, London) described a postgraduate course in microbiology, and Dr. G. Brownlee (King's College, London) a similar course in pharmacology. Both these consist of lectures and practical work. Prof. V. B. Wigglesworth (University of Cambridge) spoke on the Ph.D. and gave as his opinion that, in spite of its obvious disadvantages, this degree is on the whole worth while; but that employers should not insist on it. He deprecated the publication of theses, and Sir James Gray in the discussion went further and recommended their abolition. Dr. J. Y. Bogue (Imperial Chemical Industries, Ltd.) included, in his summary of the qualities which are desirable in the industrial research worker, a first-class education in the broadest sense, an ability to handle technicians and an ability to write English. The importance of the last was stressed by a number of speakers in the discussion, and other points that were made were that there might be scope for part-time postgraduate courses, and that workers who do not live in university towns are greatly handicapped by lack of library facilities. W. B. YAPP

MOLECULAR REARRANGEMENTS IN ORGANIC CHEMISTRY

ON April 6 a symposium was held by the Chemistry Department of Queen Mary College, London, on "Molecular Rearrangements in Organic Chemistry". Prof. D. H. Hey took the chair. The seven contributions covered those features of molecular rearrangements which are of current interest and stimulated a lively discussion.

Prof. S. Winstein described his investigations of 1:3 and 1:2 hydrogen shifts in carbonium ions. Roberts and Lee¹ had established the existence of a 1:3 hydrogen shift in the non-classical norbornyl carbonium ion; Prof. Winstein has found that the hydrogen shift does not accompany formation of the ion but occurs in a subsequent step. The first ion to be formed is the non-classical structure (I), and the subsequent migration involves as intermediate either the nortricyclonium ion (II), or the alternative structure (III). Prof. Winstein favoured the latter alternative. He then described experiments in the cyclohexane series which demonstrate the possibility of anchimeric assistance of ionization by adjacent hydrogen atoms, the ionization of appropriate cyclohexyl esters occurring more rapidly than would be anticipated and with a 1:2 shift of hydrogen.

In the subsequent discussion, Dr. H. Cardwell suggested that anchimeric assistance by adjacent hydrogen might be general in *S_N1* solvolyses and pointed out that, if this were so, a statistical correction should be applied to observed solvolysis rates, depending

on the number of hydrogen atoms able to participate. This idea was criticized by Prof. Winstein on experimental grounds. Prof. H. C. Longuet-Higgins gave theoretical reasons in support of the structure (III) for the norbornyl intermediate. Prof. M. J. S. Dewar emphasized that, although anchimeric assistance of solvolysis implies greater stability of the π -complex form of a carbonium compound with the classical form, the converse is not necessarily true. After further discussion, the consensus of opinion seemed to be that anchimeric assistance of solvolysis by hydrogen does not occur, except in special cases, but that the π -complex ions with hydrogen in the non-classical position are probably more stable than isomeric classical structures.

Prof. O. W. Shoppee discussed the stereochemistry of Wagner rearrangements in terms of the mechanism suggested by Ingold and Shoppee². In the rearrangement (IV), inversion should occur at both carbon atoms α, β , and retention of configuration in the migrating group R. Prof. Shoppee described a number of rearrangements in the sterol series, involving migrations of groups or ring contraction, where the products obtained depend on the stereochemical configuration of the starting materials and can be predicted on the basis of the theory.

Prof. Winstein pointed out that these conclusions are somewhat too rigid; while the configuration of R is invariably retained, and while C_α and C_β commonly undergo inversion, cases are known where retention of configuration can occur. He pointed out that the stereochemical course of the reaction depends on the timing of the individual processes; in particular, exclusive inversion at C_β occurs as a rule only when there is anchimeric assistance of the ionization of X.

Dr. W. J. Hickinbottom then described a number of investigations into the course of rearrangements of epoxides and related glycols. These were interpreted in terms of the current carbonium ion mechanism. Interesting new reactions are the formation of allylic alcohols from epoxides in the presence of acid, and the fission of highly substituted epoxides and 1:2-glycols into lower ketones and olefins. These reactions were interpreted as follows:

Whether or not the rearrangements of epoxides take place via intermediate glycols is being investigated.

The second session was devoted to anionotropy. Prof. W. G. Young described the reactions of allyl alcohol derivatives with thionyl chloride. Under conditions where intervention of chloride ion is avoided, the reactions proceed with rearrangement via cyclic transition states (S_N1' mechanism), for example:

In the presence of chloride ion, an alternative S_N2 reaction leads to unrearranged chloride. By suitable choice of the reaction conditions, either unrearranged chloride, or rearranged chloride, can be obtained. An S_N1 reaction can also be observed in ionizing solvents, the product from either isomeric alcohol than being an identical mixture of the two chlorides.

Dr. E. A. Braude reviewed the historical development of the concept of anionotropy, and emphasized the role of acid catalysis. He then described a reinvestigation of the rearrangement of α -phenylallyl *p*-nitrobenzoate into cinnamyl *p*-nitrobenzoate in the presence of isotopically labelled *p*-nitrobenzoic acid in chlorobenzene solution. It was shown that the reaction occurs by two distinct paths, one involving an internal rearrangement (cf. (IV)) and one a bimolecular reaction with the added acid. Both reactions are catalysed by acid. Dr. Braude concluded that no free allylic cations are involved as intermediates, the bimolecular process being of the S_N2' type; and that free allyl cations are probably not involved in anionotropy (see also *Nature*, May 8, p. 863).

Prof. S. Winstein criticized Dr. Braude's conclusions on the grounds that free ions cannot in any event occur in the solvent used, and that the work described is consistent with the initial formation of an ion-pair, which can either rearrange by 'internal collapse' or react with *p*-nitrobenzoic acid. He thought that free ions might well participate in more polar solvents. A lively discussion followed, on the distinction between ion-pair mechanisms and mechanisms involving cyclic transition-states. The conclusion appeared to be that ion pairs and covalently bound cyclic intermediates are not qualitatively distinct, but form extremes in a graded series (cf. the relation between covalent and ionic bonds). In this case the experimental evidence does not lead to a clear distinction.

The final session dealt with rearrangements in the aromatic series. Prof. E. D. Hughes outlined a general classification of reactions in which groups migrate from the side-chain to the nucleus in an aromatic system. He concluded that the main types of mechanism are an intermolecular process of the S_N1 or S_N2' type, and an intramolecular process, giving *o*-substituted aniline derivatives via cyclic transition states. The rearrangement of *N*-phenylhydroxylamine was cited as an example of the former, and the rearrangement of *N*-nitranilines, and the reaction of aniline with sulphur trioxide, as examples of the latter.

Prof. M. J. S. Dewar outlined the various types of rearrangements that occur in aromatic systems, and

emphasized the difficulty of determining whether or not they are intramolecular. If they are, classical mechanisms will not suffice, for the rearrangements often occur between widely separated centres. He outlined the π -complex mechanism for such processes and applied the idea to the rearrangements of *N*-bromoacetanilide and of hydrazobenzene. Fresh experimental evidence was cited which suggested that the former reaction is intramolecular; and a general survey of the available evidence was held to support the mechanism in the case of hydrazobenzene derivatives. In the subsequent discussion, his conclusions concerning the mechanism of the *N*-bromoacetanilide rearrangement were strongly criticized and strongly defended.

It was generally agreed that the symposium had been of value both in presenting various points of view and in clarifying ideas. A remarkable measure of agreement was reached on most of the controversial issues.

FRICITION IN RELATION TO RHEOLOGICAL PROPERTIES

ALTHOUGH a number of theories of solid friction have in the past been proposed, the one which has been most fruitful and most widely accepted in recent years is the adhesion mechanism of friction originally developed for sliding metals. According to this model, metals, when placed in contact, touch only at their high spots, and the local pressures are usually sufficient to produce plastic flow. At these regions strong adhesion occurs by a process which may be called cold welding. The strong junctions thus formed must be sheared if sliding is to occur, and this is primarily the source of the frictional resistance. With metals the deformation of the asperities is primarily plastic. Under these conditions the area of contact is proportional to the load and independent of the size of the bodies, so that the friction, too, is proportional to the load and independent of the size of the bodies (Amontons's laws).

The reality of junction formation is, shown by examining the friction tracks, which provide clear evidence of welding and shearing. This raises the interesting question as to why normal adhesion is not observed between metals. Although contaminant films may be partly responsible, the main effect appears to be due to released elastic stresses which peel the surfaces apart as the joining load is removed, so that little or no normal adhesion is detected. With soft ductile materials such as indium, where the metal can take up changes in shape of the surfaces as the load is removed, large adhesions are observed.

Clean Metals and the Influence of Oxide Films

If metal surfaces are thoroughly denuded of oxide films, Amontons's laws no longer hold. Because the surfaces are clean, they adhere strongly wherever they touch and the sliding process itself produces a very marked growth of junctions. Under favourable conditions, junction growth may proceed until the

whole of the geometric area is in intimate contact. Gross seizure occurs and ordinary sliding is almost impossible. The presence of small amounts of oxygen, however, enables sliding to occur and the friction is essentially the same as for surfaces prepared in the atmosphere.

The detailed effect of the surface oxide film depends upon the relative rheological properties of the oxide and the metal substrate. If the oxide is hard and the substrate soft, the condition is like a layer of ice on mud. Penetration takes place readily and good metallic contact occurs. The friction is high and the surface damage heavy. If, on the other hand, the oxide is ductile and can flow with the deformed underlying metal, it is better able to maintain its integrity. The friction and surface-damage may be small for moderate deformation; for sufficiently heavy deformations the surface film may be ruptured with a corresponding increase in friction and wear.

The behaviour of aluminium is of particular interest since the oxide is hard and the metallic substrate soft. Consequently, as we should expect, the thin natural oxide film offers little protection to the underlying metal. Some improvement may be obtained by artificially increasing the thickness of the oxide film by anodic oxidation. These films are, in fact, more resistant to rupture than the natural films. At small loads they maintain their integrity and the friction and surface-damage are small. With increasing load the films first fail in tension as a result of the tangential frictional forces produced during sliding. At greater loads gross disintegration of the film occurs. The frictional properties of the films depend on the surface roughness. In addition, their porosity may play an important part in trapping lubricant and so reducing the friction and wear in lubricated sliding.

Brittle Solids

The two main features of the theory of metallic friction are that cold welding occurs at the interface and that, because plastic flow takes place, the area of contact is proportional to the applied load. With brittle materials it would seem at first sight that neither of these conditions is applicable. A detailed study shows, however, that the local pressures around the individual regions of contact are sufficient to prevent brittle fracture and there is considerable plastic flow at the interface. As a result, although some surface fragmentation may occur, the behaviour is dominated by the plastic deformation of the surface layers. In addition, under the influence of high pressures and plastic flow, strong interfacial adhesion occurs. Consequently, the mechanism derived for metals is applicable; the friction is proportional to the load and of the same order of magnitude as for metals.

The high pressures existing at the points of real contact also play a very important part in boundary lubrication. The lubricant film which is sheared during sliding is subjected to pressures comparable to the yield pressure of the metal (for steel about 200,000 lb./sq. in.). Under these conditions, the resistance of the film to shear and penetration is enormously increased.

Plastics and Fibres

Other classes of materials to which the adhesion mechanism of friction may be applied are long-chain

polymers, plastics and fibres. The deformation of these materials is not, however, as clearly defined as for metals. At high loads the area of real contact is roughly proportional to the load, so that Amontons's laws are obeyed. At light loads this is no longer so. The coefficient of friction is no longer constant but increases steadily as the load is reduced. Interferometric studies show that the deformation of the surfaces is more nearly elastic than plastic. The area of contact is no longer proportional to the load, and depends on the size and shape of the specimen and on the number of points of contact. Because of this, the friction across fibres may be very different from the friction along them. If the material shows visco-elastic properties, the area of real contact at a given load will increase with the time of loading and there is a corresponding time dependency in the friction.

These and other issues relating elastic, plastic and visco-elastic properties of materials to their frictional behaviour were discussed at a symposium convened by the British Society of Rheology on February 26, on "Friction in relation to Rheological Properties". Dr. L. R. G. Treloar presided and the three main papers were given by Dr. D. Tabor, on the "Effect of Some Physical and Rheological Properties on the Friction and Lubrication of Solids", Dr. H. J. Howell on "Friction and Surface Deformation in Fibres" and Dr. F. H. R. Wright on "Frictional Behaviour of Anodic Films on Aluminium Surfaces".

D. TABOR

SCIENCE IN THE UNITED STATES

THE sixth of the annual reviews produced by the British Commonwealth Scientific Office in North America, entitled "Science in the U.S.A. for the Year ended June 1953"*, follows much the same lines as that for the year ended June 1952, which was the first to be openly published (see *Nature*, 172, 282; 1953). In its sections on the expenditure of the Federal Government on research and development, on industrial research and development, and on university and non-profit research, it draws extensively on reports issued by the National Science Foundation. A section on scientific and technological man-power is likewise based on two reports, "Student Deferment and National Manpower Policy" and "A Policy for Scientific and Professional Manpower", issued by the National Manpower Council; these are to be followed by a third, "A Policy for Technical and Skilled Manpower". The second of these reports estimates that, of the five millions now engaged in scientific and professional work, more than a million are teachers, nearly a million are engaged in medical and health services and more than half a million are engineers; but of 155,000 workers in natural science, about 15,000 are engaged in fundamental research. Shortages in different branches of science are regarded as qualitative as much as quantitative, and it is recommended that no attempt should be made to urge school leavers to turn to particular branches of study in conformity with a predetermined national policy. Instead, expansion over the whole field of higher education is suggested, so as to overcome the

* British Commonwealth Scientific Office, North America. The BOBO Review of Science in the U.S.A. for the Year ending June 1953. (United Kingdom Scientific Mission, Canadian Scientific Liaison Office, Australian Scientific Liaison Office, New Zealand Scientific Liaison Office, South African Scientific Liaison Office.) Pp. iv+44. (London: H.M.S.O., 1954.) 2s. net.

shortages without destroying the overall balance between different disciplines, and employment practices which cause inefficient utilization of professional man-power, especially in engineering, are deplored.

During the year, new restrictions were placed on the flow of unclassified reports from the Department of Defense, which is itself financing more than a third of all scientific research in the United States, and these are likely to impede the free exchange of technical information between the United States and other countries. On March 16, 1953, the two original documentation centres of the Department of Defense were amalgamated to form the Armed Services Technical Information Agency. This Agency is expressly forbidden to make even unclassified material available except for military purposes, and those engaged in defence research are entitled to receive material only in those subject categories for which they have proved a need. Furthermore, the Agency is not to undertake the direct collection of information from foreign sources or to disseminate information to foreign governments, their nationals or representatives. Much of the unclassified material is afterwards published; but now that the services provided by the Technical Information Division of the Library of Congress are no longer available to foreign countries, delays of twelve months or more may be experienced before such information becomes available. The report points out that direct exchange between institutions may now be the best avenue still open through the International Exchange Service at the Smithsonian Institution; this, however, is limited by the small funds available and the consequent necessity of using the cheapest form of freight transport, with delays normally of several months.

It is not too difficult, however, to obtain unclassified reports from some Federal departments. The Atomic Energy Commission has always fully implemented the charge laid upon it by the United States Atomic Energy Act "that the dissemination of [unclassified] scientific and technical information relating to atomic energy should be permitted and encouraged so as to provide that free interchange of ideas and criticism which is essential to scientific progress", and the report directs attention to the wide range of the physical and biological sciences covered by the publications of the Commission and listed in *Nuclear Science Abstracts*. Expenditure on the Commission's programme during the year ended June 30, 1953, is estimated at 4,000 million dollars, of which about 300 million was spent on research and development. Most of the section dealing with atomic energy in this report is concerned with the development of nuclear power for industrial or domestic purposes. In a statement issued on May 26, 1953, the Commission proposed interim legislation to permit non-government ownership and operation of nuclear power facilities, the use and transfer of fissionable and by-product materials under suitable safeguards, and the granting of more liberal patent rights than is possible at present. It also proposed to allow research and development on specific power projects to be undertaken in the laboratories of the Commission, and that a progressively liberalized information policy should be applied in the power reactor field. The objective of this policy is to further the development of nuclear plants which are economically independent of government commitments to purchase weapons-grade plutonium.

During the past year it has become evident that commercial rain-makers are losing business, but interest and activity in the physics of rain and cloud formation has greatly increased, with the growing realization of the importance of tackling fundamental physical problems first. Work continued on the theoretical and practical aspects of the use of radar in cloud detection and of radar echo-intensity measurements in the estimation of rainfall. The importance of coalescence as a mechanism in rain formation was increasingly appreciated, and the report notes a more positive attitude on the part of the United States Weather Bureau toward cloud seeding: experimental work was to start this spring in the State of Washington.

In radio astronomy, Ewen and Purcell's discovery of hydrogen-line radiation from outer space has not been followed up, although the Carnegie Institution of Washington will shortly bring into operation an extended Wurtzberg antenna, with Ewen-type receiving equipment. Practically no 'radio star' work has been done, but three prominent 'radio nebulae' have been identified with astronomical objects that can be 'seen'.

On April 14, 1952, a complete table of assignments covering the very-high-frequency and ultra-high-frequency bands was released, and there is considerable activity in the development of ultra-high-frequency receivers. The design of the high-power output stage presents the most difficult transmitter problem; and in colour television, while the Columbia Broadcasting System frame sequential method is at present the officially authorized system, the door has been left open for any other system that can be demonstrated successfully.

Capital expenditure of the chemical industry during the year is estimated at 1,500 million dollars, and this includes plant capable of producing 30 million lb. of orlon a year; 50 million dollars for new plant in New Orleans for acetylene, ammonia and acrylonitrile, and expanded facilities for the production of aureomycin; a 1.8 million dollar plant for dextran, a blood plasma substitute; a 14 million dollar project for defluorinated phosphate, one by-product of which will be uranium; and 7 million dollars for a plant for phenol by the new cumene process. Plans were also announced to spend more than 700 million dollars on new plants in Texas, Louisiana, Oklahoma and Arkansas, and increasing attention is being focused on the study of water pollution and atmospheric pollution accompanying the establishment of heavy industries. Probably the most interesting development in the plastics field is the production of new semi-permeable ion-exchange membranes in two forms, which permit the passage of anions or cations, respectively; it appears most improbable, however, that the demineralization of sea-water by such processes will be economically attractive, but with brackish waters the position is more promising.

In fuel technology a final report from the National Petroleum Council maintains the view that neither the hydrogenation nor the Fischer-Tropsch process approaches a cost competitive with gasoline from crude petroleum at 12 cents per U.S. gallon; oil shale is the only alternative source that could be considered commercially. Sufficient progress is claimed with development of low-temperature fluidized carbonization for the design of a full-size industrial unit. Development work on the hydraulic transport of fine coal has been completed, and this

method is regarded as an economic proposition with a 12-in. bore pipe-line over distances of 50-200 miles. In building, the report notes the trials made with hydraulically operated back-acting diggers thought to be suitable for digging foundations and drainage trenches; with the 'vacuum-processing' of concrete and the 'vacuum-lifting' of concrete units; and with the Tournalayer system of building, in which the concrete shell of a house is cast at a central point on a building site, and then carried away and placed on its foundations.

In mechanical engineering, considerable interest has been stimulated in the hot-forming and machining and grinding of titanium alloys, and in electrical processes for shaping and finishing hard materials, and increased attention is being given to the characteristics of machined surfaces. There has been an enormous growth of research in applied mechanics, and growing interest is also noted among engineers in the science of management and in the application of operational research to management problems. In metallurgy the shell-moulding process has attracted further attention; but phenol-formaldehyde resins continue to be the only ones of industrial importance as binders when casting alloys of relatively low melting point like those of aluminium. The production of nodular cast iron continues to increase, and American foundries are now investigating the effect of adding cerium simultaneously with magnesium to neutralize the harmful effects of residual elements.

EUROPEAN PRODUCTIVITY AGENCY

FIRST ANNUAL PROGRAMME OF ACTION

THE summary of the first annual programme of action of the European Productivity Agency, published by the Organization for European Economic Co-operation, Paris, points out that a campaign to increase productivity sets both technical and psychological problems, the latter being the more difficult and important. Some of the sociological effects of technological advances may be wholly beneficial, but others, such as the need for the worker to adapt himself to new processes or new trades, may cause temporary individual problems and require careful study. Resistance to change is not confined to labour; and it is important for it to be known that, under European conditions, higher productivity in the long run means increased possibilities of employment and that any temporary risk of technological unemployment is far less grave than that facing a community which allows itself to fall behind others in the efficient use of its resources. With proper co-operation between management and labour, even technological unemployment can be avoided, if everything is done to increase the speed of adaptation to new tasks by improving vocational training and to facilitate mobility of labour by housing policy and efficient labour-exchange services.

As regards general policy, the summary indicates that the Agency aims at giving an initial impetus to groups which can show a reasonable chance of continuing and developing with fresh sources of support and at making these continuing projects self-supporting to the maximum extent. The programme

is summarized under six main headings: specific economic and legal problems; technical and administrative problems of industry and commerce; human factors of management and labour; applied research and technology; food and agriculture; and information and general services. Under the second heading, action is contemplated to bring European management to a wider understanding of the need for management education, and the creation or development of chairs of business administration in European universities and technical colleges. Further research is also proposed on the factors determining the attitudes of employers and employees to the scientific study of the selection of workers and conditions of workers, and the pooling of experience and effort in training supervisors.

In applied research and technology, the Agency's task is essentially to supplement what is being done in existing institutions, to co-ordinate such research and to strengthen the liaison between research and industry—for example, by facilitating contacts for exchanges of information and views between those in charge of the organization and administration of research. An essential task will be to improve existing channels for disseminating technological information and the study and development of new media. The establishment and development of specialized research and information centres in the main industrial sectors will be encouraged, and special attention will be given to increasing technological productivity in the building industry.

The Agency's efforts to improve productivity in the field of food production and agriculture will be directed towards the study of the economic organization of the farm as a production unit; the factors of input in agriculture, horticulture and fisheries; the marketing and distribution of output; techniques in production processes in these fields; and the exchange of information and techniques of communication.

TRIBUTE TO PROF. ALEXANDER LIPSCHUTZ

THE combined second and third numbers of Vol. 3 of *Acta Physiologica Latinoamericana* contain a series of thirty-one essays by distinguished contributors, offered as a tribute to Prof. Alexander Lipschütz on his seventieth birthday*. The articles are variously written in English, Spanish, French, Portuguese and German. The first, by B. A. Houssay, is a laudatory biographical sketch of Prof. Lipschütz; the remainder cover a wide range of subjects—reproductive and general physiology, cancer, steroid chemistry, and numerous miscellaneous biological matters—in most of which Prof. Lipschütz has himself been an active investigator. To summarize all these interesting essays is not possible in this short review; to single out a few for special mention must place the reviewer in an invidious position. His own interests, not the excellence of the articles chosen, can be the only criteria of choice.

Prof. Lipschütz enunciated the law of follicular constancy in 1930, and two papers are directly concerned with this. M. and C. Aron discuss the nature

* *Acta Physiologica Latinoamericana*. Vol. 3, Nos. 2 y 3: Número de Homenaje al Profesor Alejandro Lipschütz. Pp. vi+49-802. (Buenos Aires: Asociación Científica e Investigación, 1953.) n.p.

of the reactionary hyperactivity in the remaining ovary after unilateral ovariectomy and the factors involved in its genesis. S. Zuckerman summarizes the recent researches in his department on the question of oogenesis in adult animals and concludes that this does not occur in the rat, rabbit or monkey, though it may in the lemur, armadillo and guinea pig. Another paper with some bearing on this subject, though with far wider significance also, is that by A. S. Parkes on the conservation of gonadal tissue by deep freezing after glycerol treatment. Such tissues, after apparently indefinite storage, may behave much like fresh material on grafting.

There are a number of papers dealing with cancer research. F. Bielschowsky, discussing the influence of the ovaries on the production of chemically induced cancers, states that mammary cancers were obtained in nearly as high an incidence in rats bearing ovarian grafts as in intact animals, and that such tumours developed whether the graft formed corpora lutea or not. B. A. and A. B. Housay, A. F. Cardesa, V. G. Foglia and R. M. Pinto describe the adrenocortical tumours which develop slowly in white rats after gonadectomy. Many of these tumours eventually elaborate oestrogens, under the influence of the pituitary gonadotrophins. A. Lacassagne, L. Hurst, F. Zajdela and R. Royer, writing on the experimental production of cancer of the liver, conclude that there is no sex difference in susceptibility, and that oestrogens decrease the susceptibility, while castration of the male, the administration of testosterone to oestratees of both sexes, or of progesterone to oestrate males, increases it. A brief paper by Peyton Rous reviews cancer research over the years.

Problems relating to the action of reproductive hormones are considered in another group of papers. John Hammond writes on the effect of the plane of nutrition on hormone action, and on the curious way in which uterine infections in cattle occur much more readily under the influence of progesterone than of oestrogens. F. J. A. Paes, E. M. van Soest and S. E. de Jongh conclude that androgens take no significant share in the development of the secondary sexual characters of the female rat. C. D. de Pasqualini describes the effects of adrenal grafts in adrenalectomized rats; in such animals there is luteinization of the ovaries or hyperplasia of the Leydig cells of the testes. Some abnormality of function of the adrenal graft appears to lead to the secretion of excessive amounts of pituitary luteinizing (or interstitial-cell-stimulating) hormone. The relations between the gonads and the adrenal cortex are also discussed by A. D. da Costa. Gregory Pincus and M. C. Chang confirm the effectiveness of progesterone as an inhibitor of ovulation in the rabbit, and they also discuss the effectiveness of other related steroids.

Among the papers on steroid chemistry, R. Courrier writes on the allenolic series of artificial oestrogens, E. C. Dodds on the relation of stilboestrol to naturally occurring oestrogens, and Christian Hamburger on the ultra-violet absorption spectra of oestrogens. K. Miescher, A. Wettstein and F. W. Kahnt demonstrate the conversion by adrenal homogenate of 9:11-dehydro compound-S acetate into its 11- β -hydroxylated derivatives (17-hydroxy-corticosterone and its acetate), and this finding, they conclude, strengthens the supposition that 9:11-dehydro-steroids may represent important intermediates in the metabolism of the adrenal cortical hormones.

Other essays in this interesting collection deal with aspects of diabetes (V. G. Foglia; O. Koref, L. Vargas and A. Vukusic); cardiac activity (B. Gunther; F. Hoffmann, S. Middleton, A. Molina and J. Taleanik; O. Orías); hormonal factors in the development of inflammation (H. Selye); the discovery of uterine smooth muscle (G. W. Corner); histochemical reactions of mast cells (W. Buño); and a variety of other topics including renin, the cytology of urinary sediment as an indicator of oestrogenic stimulation, respiratory control, motor nerve section, the neurovegetative system, and certain factors influencing the voluntary intake of alcohol by rats. G. I. M. SWYER

FORESTRY IN THE SUDAN

THE annual report for July 1951-June 1952 of the Forest Department of the Sudan* is a very full and discursive document of sixty-nine pages and deals with many sides of what should be wholly the work of the forest officer alone. As an introduction, the report states "the brief description of the distribution and main uses of the forests which has been included in previous reports is repeated here". The statement of the forest policy in force, laid down in 1932, which is given in full in chapter 2 of the report, defines the division of responsibility between the Chief Conservator and governors of Provinces. The latter are responsible "for ensuring that the permanent supply of forest produce is sufficient to meet the internal requirements of their Provinces". Governors are, moreover, "empowered to declare as Provincial Reserves such areas as they consider necessary"; they are "to prepare programmes in accordance with their estimated future provincial requirements and engage staff to carry them into effect". It might be logically asked—What is the Forest Department for? The statement adds that "expenditure in this connexion will be borne by province budgets and that Governors may refer to the Chief Conservator for advice".

The Chief Conservator writes in this annual report that "twenty years have now elapsed since this policy was laid down and it is timely to review results. They are not wholly satisfactory." The provincial forests made by Governors during the period only amount to one thirty-seventh of the area of the reserved forests owing to the very natural preoccupation of provincial administration staffs with other duties and a lack of appreciation of the fact that forestry is essentially a long-term business. A revealing comment from the report is that "forestry is so dwarfed by State Agriculture in the Sudan that it is not often realized that the scale of all-round forestry here is now greater than in other African territories of comparable resources", and, it might have been added, though the forestry staff is much smaller.

The wonderful success of the Gezira undertaking placed the Agricultural Department in its present position in the administration of the Sudan. Had the gum arabic, a purely forest product, been placed under the management of the Forest Department as it logically should have been, the annual revenue received, a considerable portion of the Sudan's

* Sudan Government Forest Department of the Ministry of Agriculture. Report for the Period July 1951 to June 1952. Pp. iv + 70. (Khartoum: Ministry of Agriculture, Forest Department, 1953)

annual budget, instead of being credited to the district revenues would have come to the Department. The latter would have had long ago sufficient strength to put in force the urgent variety of work which, the report shows, is now being attempted. If it is necessary to train the forester for his duties, it follows that they cannot be carried out, nor even fully understood, by other elements of the administration. The striking example is the collection of the valuable gum arabic by the people under the aegis of the civil administration to which, as has been said, is credited this valuable revenue. It brings to mind the old days, during two-thirds of the last century in Madras, when the revenue authorities considered that the forest officer could only exercise his duties in the heavy timber forests, chiefly situated in the western half, and that he had no jurisdiction in the scrub forests in the eastern half of the Presidency, the produce of which was credited to the district revenue with no supervision over its collection. The points of view of the Governor-General and the Secretary of State for India in this matter were at length accepted by Madras, and all forests and their products, including timber-producing or scrub valuable for firewood and grazing and some other minor products, were placed under the Forest Department and all revenues therefrom credited to that Department. It is not too much to believe that, had the gum arabic product been placed under the Forest Department in the Sudan even as late as 1932, the methods of collection and regulation of the so-called 'gardens' would have long ago been under a working plan and a larger annual revenue could be now realized (see para. 179 of the report).

With the comparatively recent expansion of the work during 1951-52, 496,469 feddans of new reserves were gazetted, bringing the total of reserved forest up to 722,553 feddans (1,178 square miles), which seems very little to show for fifty years of work. But taking areas under reservation, the area totals 3,051 square miles, representing 0.314 per cent of the total area of the Sudan. It is noted in the report that Uganda has already more than 7 per cent of reserved forest. In knowledgeable quarters it is judged that 15 per cent of well-distributed forests is none too much for safety in an arid tropical country. A very considerable amount of planting has been carried out during the year, a large planting campaign having been organized.

The staff of the Department amounts to twenty officers (two under training in the United Kingdom) and seventy-six in the subordinate ranks, other than forest guards, who are not mentioned. If this staff was doubled it would scarcely be able to carry out all the duties facing a Forestry Department entrusted by its Government to undertake all the forestry work in the country. Enumeration surveys of all forests of commercial value, in which saw-mills appear to be multiplying, and, perhaps even more important, investigations into the ownership of supplies from which the large demands for firewood and charcoal are being obtained, would appear to be urgent. For example, one reads in the report on this subject: 'For the southern division the Conservator writes of the increased prosperity in Khartoum Province, reflected in much building with an accompanying increase in the demand for firewood to burn the bricks. The demand far exceeded the supply of firewood imported by the Department into Khartoum Province on rail, with the result that the illicit cutting of desert 'scrub' forest showed an unwelcome

increase, although no widespread devastation took place.' Who is to be the ultimate sufferer through the 'illicit cutting of the desert 'scrub' forest'? Moreover, who is the authority directly responsible? Is it the Forestry Department?

In the seventies of the last century a somewhat similar situation arose in the so-called *ruths* in the Punjab plains, covered by a desert scrub, on account of its use for firewood. The newly building railways demanded wood fuel for running the engines and wished to have the exclusive use of the scrub; the calculations of the possible available amounts included digging out and utilizing the roots, thus ensuring a resultant desert. This was prevented by placing the management of the *ruths* under the management of the Forest Department, which, as the Secretary of State said, had been brought into the administration and trained for the purpose of undertaking this type of work. E. P. STUBBING

ROBERT JAMESON AND THE ROYAL SCOTTISH MUSEUM, EDINBURGH

A PAPER by Mr. V. A. Eyles on 'Robert Jameson and the Royal Scottish Museum', published in the April issue of *Discovery*, is particularly appropriate in view of the centenary this year of the Royal Scottish Museum, Edinburgh, for it was through Jameson's enthusiastic labours in the College Museum that eventually it attained such a status that it was taken over by the State. In a foreword, Mr. Eyles describes the origin of the University of Edinburgh and its relationship to the civic authorities. He then records the circumstances of the establishment of the chair of natural history and its progress under Dr. Robert Ramsay, Dr. John Walker and Robert Jameson, who succeeded in 1804.

The professor of natural history was *ex officio* keeper of the Museum, and Jameson, in addition to a long and distinguished career as a naturalist, was also zealous in his care of the collections. Eventually geology became his chief subject, and he was caught up in the great Huttonian-Wernerian controversy. He studied under Werner in the mining town of Freiberg for nearly two years; and Eyles records that he 'absorbed uncritically all that he [Werner] had to say' and eventually became the greatest protagonist for Wernerism in Britain. But his enthusiasm for geology did not mean the neglect of the other branches of natural history, for he lectured on meteorology, hydrology, mineralogy, geology, botany and zoology—truly a formidable list. The general impression among his students, including Charles Darwin, was that the lectures were rather dull but accurate, and unrelieved by any humour or figures of speech.

As a museum man, Jameson experienced all the trials of a present-day curator, including lack of accommodation and funds. In 1852 Jameson prepared a report on the Museum, and eventually the collections were accepted by the State in 1854. The foundation-stone of the Royal Scottish Museum in Chambers Street was laid by the Prince Consort in 1871. All interested in the history of geological studies and their influence on contemporary thought are indebted to Mr. Eyles for his painstaking paper.

BOOK REVIEWS

CELL PHYSIOLOGY

Pathology of the Cell

By Prof. Gordon Roy Cameron. Pp. xv+840+64 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1952.) 84s. net.

AS text-books on a major subject like pathology get increasingly larger they tend to become reference books and few students can be expected to read them from cover to cover. Many books of this kind are in essence scarcely more than carefully systematized descriptions of abnormal microscopic and macroscopic structure. The sequence of the chapters, though often varied with considerable ingenuity, does little to conceal the essential sameness of the information. It is indeed difficult to present a major subject in an entirely new way because systematization and the burden of accumulated facts allow almost no scope at all for the broader concepts and freedom of treatment characterizing many works in the literature of biology as a whole.

Prof. Gordon Cameron has written a book of monumental size and quite exceptional scholarship. It is not a conventional text-book of pathology or a standard work of reference on morbid histology, but a very fascinating story in which function and structure in disease have been linked with what is known about normal and abnormal cells. The text consists of four parts: the normal cell, the abnormal cell, a critique of the cell theory and cellular pathology in the future.

In the past decade or so cellular physiology has undergone amazing progress. It is everywhere predominant in this book, the material of which ranges from plants and protozoa to man. The author deals extensively with the historical development of the cellular theory which some may hesitate to read fully because there is so much else which commands attention in the more familiar modern era of the subject, or perhaps because not everyone can be as deeply interested as the author in the philosophies of the German nineteenth-century science. Each chapter, however, has a concise summary and so one can delve deeply or superficially as the spirit moves.

Prof. Cameron is no pundit concealing the sources of his knowledge for the sake of brevity or elegance of style. In fact, this book might almost be said to be excessively documented to the extent of being difficult or uncomfortable to read. This is a fault not of style but of the technique in correlating the references lists with the text. If each paper quoted had been given a serial number inserted quite inconspicuously at each appropriate point in the text there would have been no need to interrupt some sentences with a list of authors' names and dates, sometimes extending over half a page.

The chapters on cellular degeneration and inflammation are especially noteworthy for a functional, rather than a morphological, approach. The vital biological process is envisaged rather than the static pathological state. But clearly the author is restless for the fruits of the almost unlimited field which the investigation of the sub-microscopic normal and abnormal structure is bound to provide. The pathology of the future, which is outlined in Part 4 of this book, is both imaginative and stimulating.

There are more than six hundred pages of text, with an excellent bibliography and subject index. The numerous illustrations are well reproduced, but a few of them appear to have been inserted more as an afterthought, marrying somewhat awkwardly with the text.

Written over a period of eleven years this book cannot fail to be a source of constant inspiration to research pathologists and biologists. It is indeed a remarkable achievement.

E. S. HORNING

SOCIAL BEHAVIOUR OF BIRDS

The Herring Gull's World

A Study of the Social Behaviour of Birds. By Dr. Niko Tinbergen. (The New Naturalist Series.) Pp. xvi+255+30 plates. (London: William Collins, Sons and Co., Ltd., 1953.) 18s. net.

THIS is a fascinating book. It consists of a detailed account of the ordinary behaviour of a common bird; but it is full of scientific interest in the physio-psychological analysis of these activities. It is rigorously objective and exact in its treatment; but its clear expositions are pleasantly free from all but a minimum of technical terms. The only subjective note that is allowed to intrude is one of keen enjoyment on the part of the investigator; and that the reader will find infectious.

Here modern ideas of animal behaviour, on which Dr. Tinbergen—formerly of Leyden, now of Oxford—is a distinguished authority, are exemplified in a single species. The behaviour of the herring gull is minutely followed throughout the season when close observation is possible, from first arrival at the nesting colony, through pairing and incubation, to the phase of family life. That the author is one of those students of behaviour who prefers to make his observations in the field rather than the laboratory, even when experimental methods are used, will earn the sympathy of readers who are primarily naturalists.

The herring gull's world is seen to be governed by a few major drives or internal urges. Under the influence of whichever predominates at the time, the bird shows a delicate sensitivity to special external stimuli and a capacity for reacting to these by corresponding special types of behaviour. When the response to a particular stimulus is innate, it is rigid and almost automatic, unilluminated by insight into the ends served: the reaction to hard food is to fly up with it and drop it from a height; but experience brings no awareness that the food must be dropped on hard ground for the behaviour to be effective. Yet, in other cases, a reaction may be 'conditioned' by learning: the bird quickly learns to recognize its own mate, and learns to recognize its own chicks (although never its own eggs) within about five days.

One of the reactions most closely studied here is that of the chick seeking food by pecking at the red spot on its parent's beak. Experiments with dummies of various shapes, sizes, patterns and colours demonstrated how definite this is. The response is indeed evoked by a red spot when presented without any-

thing otherwise resembling beak or bird; and the chick may repeat it hundreds of times in spite of failure thus to obtain food. It is even possible to evoke a "supernormal" response by exaggerating the feature; and in this regard the author cites woman's use of lipstick as an analogy.

Much that is most puzzling in the behaviour of birds becomes explicable in terms of 'displacement activities', in accordance with what Edmund Selous long ago called "the law of the interchangeability of energies". When an urge is frustrated, it finds an outlet in some action belonging to quite a different context—like the cat, suddenly unsure of itself, which stops to wash its face. These irrelevant actions are often characterized by being incomplete and may become stereotyped in a ritual form. Actions of this type make up a large part of the behaviour of birds, and not least in those species which are markedly social in the reproductive phase of their lives.

The interesting explanation is offered of the pair's defence of 'territory' around the nest, in the case of a colony on open ground, that dispersion adds to the value of the cryptic coloration of eggs and young. The observed effect of predation is indeed a wider spacing of the nests when the birds lay again.

Dr. Tinbergen frankly enjoys wrestling secrets from the living things which he studies. He likens his pleasure to that of the chase: "I am not in the least ashamed," he says, "to confess that my photographs and this book are my trophies." Many will gain by examining them.

LANDSBOROUGH THOMSON

NATURAL HISTORY OF THE PINKFOOT GOOSE

A Thousand Geese

By Peter Scott and James Fisher. Pp. 240 + 17 plates. (London: William Collins, Sons and Co., Ltd., 1953.) 21s. net.

THE late Gino Watkins once quoted to us: "When a man really wants to do a thing, he will succeed". Peter Scott certainly demonstrates the fundamental truth of this seemingly sweeping statement. Urged by a deep-rooted interest in water fowl, almost bordering on an obsession, he has managed to bring together a unique collection of live Anatidae on the New Grounds near Slimbridge, has travelled widely for the purpose of collecting and observing out-of-the-way species, and has recently embarked on a very ambitious population study of the pinkfoot, a goose wintering mainly in Britain and breeding in the Arctic. This idea was conceived at a time when it was not yet known for certain where the main breeding colonies of the species were.

At first, in the late 'forties, the geese were captured (with the now famous rocket-net technique), ringed and otherwise marked on various wintering grounds in England and Scotland; but in 1950 Scott decided to go to the heart of Iceland where, he had strong reasons for believing, the largest breeding colonies must be found.

Together with Miss Philippe Talbot-Ponsonby (now Mrs. Scott), the well-known Icelandic ornithologist Finnur Gudmundsson, and James Fisher he set out in June 1951, and in the beginning of August returned, having found the large colonies which he knew must be there, having made provisional counts,

and having ringed 1,151 geese—a remarkable achievement.

"A Thousand Geese" is the narrative of this expedition, written in a simple, straightforward style, which brings out the atmosphere of such a delightfully single-purposed enterprise, during which a man, while working hard, can get a good mental rest by living close to Nature.

In a footnote at the end of the book Scott adds that he went again in 1953 and that this time, using the experience gained in 1951, he caught 9,005 geese. According to his estimates about "one in five of the world pinkfoot population now carries a ring". The repeated sampling makes calculations of the Iceland population possible, and the large-scale ringing will provide valuable data on various aspects of pinkfoot population ecology. Excellent planning, great tenacity of purpose, and exceptional skill has enabled him to make this admirable start.

Apart from the story, the book contains, in an appendix, detailed information on the status of the pinkfoot in Spitsbergen, on its status in Greenland, notes on the birds observed at the camp site, a list of plants found (compiled by Gudmundsson), estimates of the local pinkfoot population, and a bibliography of the breeding distribution of the species.

The illustrations are excellent, and special mention should be made of the very attractive book-jacket.

N. TINBERGEN

A HANDBOOK FOR BIRD- RINGERS

Bird-Ringing

The Art of Bird Study by Individual Marking. By R. M. Lockley and Rosemary Russell. Pp. viii + 119 + 8 plates. (London: Crosby Lockwood and Son, Ltd., 1953.) 9s. 6d. net.

R. M. LOCKLEY is a 'pioneer of British bird observatory work, and few ornithologists can have exceeded his total of birds personally ringed. He also has many European correspondents in this field, and his collaborator, Mrs. Russell, has had recent experience of North American 'banding' methods. Their first three chapters are written most entertainingly and describe the history, value and technique of bird-ringing succinctly but with interesting illustrations. At the same time, there is a needed emphasis on care. Bird trapping and ringing have become enormously popular in recent years and have attracted a large number of enthusiasts with little previous knowledge of ornithology. But birds are delicate organisms, and it is essential scientifically—as well as most desirable on humane grounds—that they should be caused as little discomfort as possible when they are caught and afterwards handled.

More than half the book is taken up with illustrated descriptions of traps and other catching devices. This is quite reasonable. Provided the need for care and gentleness is realized, the actual process of ringing a bird is simple and, in any event, can only be learnt in the field. The real art lies in catching the bird. Most of the designs have already appeared in the first field guide of the British Trust for Ornithology (1950) by P. A. D. Hollom, but the authors have various developments and modifications to record and add some useful American patterns excluded by the Trust's booklet.

The final chapters deal with recording and field equipment, and glance at the ancillary techniques of weighing, measuring and parasite collection. A full list of the British bird observatories makes an important appendix. The authors exclude, however, any detailed references to ringing outside the British Isles on the grounds that the literature received was "far too voluminous"; but a list of the more important schemes would have been welcomed and could have replaced the four pages devoted to a "Model Life-Study by the Ringing Method". Some of the works mentioned in the text by abbreviated titles are not recognizable in the "Select Bibliography", which includes remarkably few titles directly relevant to ringing methods and thus at least shows the need for this well-produced little handbook.

BRUCE CAMPBELL

WEST AFRICAN "BEEF"

The Overloaded Ark

By Gerald M. Durrell. Pp. 238. (London: Faber and Faber, Ltd., 1953.) 15s. net.

THIS is an account of a collecting trip to West Africa by two naturalists who were determined to go to the tropics and enjoy the wild life of them, but who could raise the necessary money only by undertaking to collect wild animals for European zoos. They came back poorer financially than they left; but they did manage to cover the greater part of their expenses, and they were enormously enriched by their experiences. Gerald Durrell and his companion, John Yealand, are excellent naturalists, and the first, who, against the advice of the second, has written this book, has the flair for writing that runs in the family and has produced a most entertaining volume.

The steaming forests of the Cameroons teem with animal life if only you can find it; but the human collector toiling painfully on foot through the tangled undergrowth is at a great disadvantage compared with the animals that can creep under the obstructions, swing from tree to tree over him, or soar into the air above everything. By enlisting the help of the natives who have been born and bred in the forest it is, however, possible to come up with the wild creatures and to capture specimens of "beef", as the wild animals of the region are called in the local pidgin.

The author and his companion were able to get together a good collection of birds and animals—perhaps the most interesting of them all were the angwantibo and the otter shrew. The angwantibo, *Arctocebus calabarensis*, is a very rare lemuroid found only in the forests of the British and French Cameroons; there are very few specimens in museums, and it had never been brought alive to Europe. Scarcely a single zoologist had ever seen it alive, and practically nothing was known of its way of life. After much fruitless searching a native casually brought one in, caged in a basket of palm leaf; it placidly accepted captivity and was successfully brought to the London Zoo. *Arctocebus* much resembles the potto; it is nocturnal, spending the day asleep clinging to a branch with its head tucked down between its arms, becoming active at night and feeding upon fruit, insects and meat. Durrell was also fortunate enough to obtain two otter shrews, or giant water shrews (*Potamogale*); but after they

had apparently settled down comfortably in captivity they both inexplicably died. The account of the finding and capture of the first in the middle of the night under a rock in a mountain torrent is a splendid bit of descriptive writing, as indeed are many other passages in the book. The natural diet of the otter shrew appears to be freshwater crabs, for of all the food-stuffs offered they were the only things eaten. The author was able to wean them on to an artificial diet which seemed to suit them well until their sudden deaths showed that something was lacking. Such are the delights and disappointments of the animal collector.

This is an excellent travel book that really gives the reader the feel of the tropical forests of West Africa; it is vivid but objective, and avoids purple passages—it will fill naturalists with envy of those whose enterprise took them on such a fascinating zoological journey. The skilful line drawings by Sabine Baur are an ornament to the work.

L. HARRISON MATTHEWS

CULTURE OF ALGAE

Algal Culture

From Laboratory to Pilot Plant. Edited by John S. Burlew. Pp. ix+357. (Publication 600.) (Washington, D.C.: Carnegie Institution of Washington, 1953.) 1.25 dollars.

IT has not often happened that a scientific programme of uncertain outcome, which is only worthwhile if it has practical results, has attracted so much attention, so many fertile brains and even very considerable funds. In biology it has happened for the first time.

The reason is the obvious necessity to supplement our normal field-crops, which cannot be increased much above the present level, with some kind of food of a different origin. The rising number of inhabitants of the earth, due to reduced mortality, puts pressure on our inventive capacities, and one hopes to find a way out with the help of algal cultures.

Conforming with the general tendency of our time to plan ahead, means and energy are being directed towards growing algae on a gigantic scale which, twenty years ago, would have appeared ridiculous to propose. Compared with the food value of the algae hoped for, the transformation of radiant energy plays a minor part in the discussions.

At present the solar energy reaching the earth is, to a large extent, wasted. No better means for utilizing it is known than the pigment system of green plants, and it seems more reasonable to use the algae produced, if sufficient quantities are forthcoming, as a food for man and animals than to burn them in boilers. The notion of growing algae as food was conceived in Germany by O. Warburg during the First World War, but did not begin to stimulate action until the Second World War, and then mainly in the United States, while minor efforts are reported from Great Britain, the Netherlands, Israel, Germany and Japan.

The main aim is to attain optimum utilization of radiant energy from the sun; the main difficulty being the protection against infection with other, for example predatory, organisms. A closed, though not necessarily sterile, apparatus of enormous dimensions is required. One hopes to produce a larger amount of

dry organic matter with algae than with customary field-crops which cover the ground and form an almost uninterrupted photosynthetic layer only during a short part of the year.

A great effort is directed towards the elucidation of the main factors in algal growth and reproduction, for example, the effect of light-intensity, temperature, different nutrient solutions, density of cell-suspension, intermittent light, etc. At the same time, the dimensions of the experiments are steadily increased, from test-tubes and flasks to large bottles and so on, eventually to pilot plants.

So far no alga has proved superior to *Chlorella pyrenoidosa* in productivity; but it seems possible that other properties may in future play a part: among others, easier harvesting, hardness against high temperatures as caused by insolation, or against chemical admixtures to the ordinary agricultural fertilizers which will have to replace the pure chemicals now in use.

The contributions by various authors are of unequal value. Those who believe that pure cultures are not indispensable for achieving heavy yields continuously are in the minority but not yet defeated, although their achievements are not impressive. Some new discovery may alter that. There is a great deal of information in this volume which will stimulate research in many ways. E. G. PRINGSHEIM

PLANT GENERA

Plant Genera

Their Nature and Definition. A Symposium by G. H. M. Lawrence, I. W. Bailey, Arthur J. Eames, Reed C. Rollins, Marion S. Cave and Herbert L. Mason. With an introductory essay on Generic Synopses and Modern Taxonomy by Theodor Just. (*Chronica Botanica*, Vol. 14, No. 3.) Pp. 91-180. (Waltham, Mass.: The Chronica Botanica Co.; London: William Dawson and Sons, Ltd., 1953.) 2 dollars.

THE genus occupies an important place in the hierarchy of taxa. Historically, it was recognized as a reasonably clear concept before the species or the family. Nomenclaturally, it is the basis for the manufacture of most family names and forms the specific name in combination with the specific epithet. Phytogeographically, the ranges of genera provide data (and problems) that are often of greater significance than those yielded by the ranges of species or families. There are thus valid reasons for periodically reviewing the generic concept.

The symposium on plant genera to which notice is given here was apparently largely initiated by Dr. F. Verdoorn, the editor of "*Chronica Botanica*", who contributes a foreword in which he pleads for "a national or international scheme which will result in the preparation of a complete, somewhat uniform, series of generic floras".

In an introductory essay Theodor Just notes that we now recognize the need for different kinds of genera and, while supporting the scheme for generic floras, shows that these must be prepared by long-term team work. G. H. M. Lawrence refers to various taxonomic "trouble-spots" and declares his belief "that the answers will not be found, until we taxonomists function as synthesizers, until we focus on each problem all the pertinent data to be had from related fields of botanical effort". This emphasis

on what has been called synthetic taxonomy is increased by other contributors, as by I. W. Bailey in an anatomical approach, A. J. Eames for floral anatomy, R. C. Rollins with regard to cytogenetics, M. S. Cave for cytology and embryology, and H. L. Mason in dealing with the role of plant geography in taxonomy.

As many of the writers clearly point out, no one set of criteria, no group of characters from a restricted field can alone result in a widely satisfactory delimitation of genera (or other taxa). The difficulties, practical and theoretical, of utilizing diverse 'characters' in taxonomy are not to be gainsaid. Much modern work has shown that they can be overcome and that the results can be expressed, at least to a very large extent, within the existing framework of taxonomy. Subsidiary schemes are often useful if only temporarily and within narrow limits, but no general replacement of the species-genus-family hierarchy has yet been proposed and tested to meet with wide acceptance.

The idea of preparing "generic floras" or "genera plantarum" to include all cryptogams and phanerogams needs careful consideration. Genera are composed of species and, concretely, species are composed of individuals. It may be argued that delimitation of genera should succeed, not precede, the study of the species involved. In other words, if the modern methods of synthetic taxonomy be accepted, monographic work is essential before the genera can be satisfactorily determined. There is a danger in deciding on generic criteria and generic limits without fully examining every species and ultimately every available specimen and all data. It is true that a genus can often be adequately determined without settling every specific and intra-specific nomenclatorial problem but not without fully studying the 'characters' of, and within, all the species and specimens available. The question then arises: "Is it not worth while spending the extra time and properly monographing the group?" W. B. TURRILL

CHEMISTRY OF TISSUE SECTIONS

Histochemistry

Theoretical and Applied. By Dr. A. G. Everson Pearce. Pp. viii+530+35 plates. (London: J. and A. Churchill, Ltd., 1953.) 60s. net.

AS Dr. Pearce says in his preface: "Histochemistry can transform the descriptive sciences of biology into dynamic and functional sciences". His book "is an endeavour to compass the whole of histochemistry as applied to tissue sections".

The book opens with a short chapter on the history of histochemistry, followed by a discussion of fixation and freeze drying. Then proteins, nucleic acids, carbohydrates, lipids, carbonyl compounds, various enzymes, pigments and inorganic constituents are treated in succession, and to conclude there are brief chapters on physical methods and appendices, compiled in 'cookery-book' style, on histochemical procedures.

To write a text-book on a subject which is still in its early stages of development is to offer many hostages to fortune. What fortune will do with them remains to be seen. In the meantime this book constitutes intelligent comment on the present position in histochemistry, which will be of interest

to all who are concerned in the scientific development of the field. The appendices will be appreciated by the many workers who are beginning to make empirical use of histochemical methods.

The discussion in this book is most valuable when it is concerned with problems in organic chemistry and biochemistry, and is notably weak on the physical side. Since the main intention of the author is to facilitate qualitative and diagnostic studies, which depend on chemistry rather than physics, the weakness on the physical side is not of major importance.

The chapter on freeze drying is the best of the physical sections. For the most part it wisely follows the recent publications of L. G. E. Bell, and where it deviates is liable to error: for example, on p. 36 the dryer manufactured by Edwards and Co. is classified among the outmoded vapour-trap dryers, whereas it is an approximation to a mean free path dryer. The discussion of diffusion errors is very limited in its scope. The chapter on physical methods devotes less than two pages to the techniques of visible and X-ray spectrophotometry, doing quite inadequate justice to the work of Caspersen, and not mentioning the valuable contributions of Wilkins and other members of the King's College biophysics group. There is also a tendency to underestimate the importance of the work of a number of authors, for example, Brachet, Bourne, Caspersen, Chèvremont and Verne, and perhaps to be overkind to the present reviewer. These faults, however, are minor in relation to the author's purpose.

This work has a double interest, being of value both to those who wish to develop histochemistry as a precise scientific tool and also to those who wish to use histochemical methods in a manner analogous to histological procedures. The usefulness of the latter point of view is sometimes under-estimated. It does not matter, for example, that a histologist does not know exactly why a section stains with haematoxylin and eosin, provided the results he obtains are repeatable and assist diagnosis in a reliable way. Similarly, a histologist may use histochemical techniques for staining sections and will be justified if he is thereby assisted in diagnosis. Whether the method is a precise one on the chemical and cytological level may be irrelevant.

J. F. DANIELLI

MALE STERILITY

La Sterilità nel Maschio

Fisiopatologia degli Organi della Riproduzione. Diagnostica e Terapia dell'Infertilità Maschile. Da Guglielmo Longo. Pp. xix+520. (Salerno: Diffusione Scientifique Internationale, 1953.) 4000 Lire.

GYNAECOLOGY is a branch of some antiquity in medical science: its counterpart, andrology, has been practically non-existent as such until relatively recently; in fact, it is only beginning to emerge in emancipation from general medicine, endocrinology and urology. The reason for this may be sought, partly at least, in the circumstance that in the not so distant past the blame for involuntary conjugal sterility has been conventionally apportioned to women, nearly all earlier attempts at clinical investigation having been resisted and scornfully rejected by the 'stronger' sex. However, for some time now, it has been dawning upon clinicians and

scientific observers alike that, in a hitherto unsuspected proportion of cases—at least 25 per cent of the total number of sterile marriages—it is the male partner whose sterility or subfertility lies at the root of the trouble.

Quite apart from these considerations, recent years have witnessed an upsurge in scientific, socio-economic and medical interest throughout the entire field of human reproduction; this being amply reflected in the formation in most countries of the world of learned societies concerned with the study of fertility and sterility in the human race. Thus, in Great Britain there exists the Society for the Study of Fertility, which publishes annually its Proceedings; and in the United States, the American Society for the Study of Sterility, which publishes the periodical *Fertility and Sterility*, occupies a similar position.

The aim of Dr. Longo's treatise on sterility in the male is twofold: (1) to co-ordinate and disseminate modern knowledge in the field of human reproduction; (2) to focus the attention of his medical colleagues upon the responsibility of the male partner in marital sterility. The book is composed of four parts, of which the first deals at length with the anatomy of the male reproductive tract, physiology of reproduction, including its sex-psychological aspects, semen morphology, and endogenous and exogenous factors which influence semen characteristics; the next part is concerned with more specifically clinical aspects of male infertility due to anatomical or endocrinological causes; Part 3 is a survey of clinical and laboratory methods of semen evaluation, pp. 397-441 offering a detailed account of current methods of semen analysis; the last part of the book is devoted to preventive and therapeutic measures to be adopted in cases of male subfertility; a brief outline of the technique of testicular biopsy and vasopuncture is included.

The literature is conscientiously quoted and the author is equally appreciative of European and American scientific work. The text is lucidly written so that it is possible to follow without difficulty the gist of each section even if, like the reviewer herself, one can claim but limited knowledge of Italian. Some of the illustrations would doubtless benefit from the use (in a future edition) of higher quality paper. Coming from the home of some of the most illustrious pioneers in the field of reproduction, to name only Malpighi, Spallanzani, Mantegazza, Sertoli, Dr. Longo's is an effort thoroughly worthy of the tradition established in Italy by those early investigators and actively maintained by the present generation of scientific and medical research workers.

C. LUTWAK-MANN

COMPARATIVE PHYSIOLOGY OF ANIMAL PIGMENTS

Animal Blochromes and Structural Colours

Physical, Chemical, Distributional and Physiological Features of Coloured Bodies in the Animal World. By Dr. Denis L. Fox. Pp. xiv+379+3 plates. (Cambridge: At the University Press, 1953.) 60s. net.

IT is unusual indeed for a work on animal colours to be as comprehensive as this latest review by Prof. D. L. Fox. The compression of a vast amount of material into a limited space can so often result

in a treatise of interest only to the specialist. But in this case the author's consciousness, his first-hand knowledge of so wide a field in this domain and, above all, an enthusiasm born of æsthetic appreciation of the wonderful diversity of natural coloration have yielded a work which will command interest throughout, and even beyond, the realm of biology.

The author has himself made notable contributions to our knowledge of structural colours in animals, and his authoritative discussion is a welcome addition to the rather infrequent reviews of this fascinating subject. Many readers will no doubt be surprised to learn of the extent to which structural colours occur as a result either of scattering (Tyndall blues) or of interference at a laminated surface (iridescence of birds and insects). Further examples are found in the 'structural whites' of butterflies, while the elytra of the genus *Serica* carry an accurately ruled diffraction grating with 0.8- μ spacing. A preliminary account of the physical basis of colour is given in terms which, though elementary, are adequate for an appreciation of the colour-producing tegumentary structures of which numerous examples are described.

That the chapter on carotenoids is the largest is scarcely surprising in view of the author's eminent position in this field. While the chief emphasis is on comparative physiology, useful but necessarily brief discussions of carotenoid chemistry and of isolation methods are included. A great difficulty in surveying these pigments lies in the multiplicity of reports on their isolation and their prompt naming after the animal origin. To classify the numerous synonyms and to produce a balanced review requires a deep inside knowledge of the development of carotenoid studies. There is no doubt that the chapter will be regarded as an outstanding contribution to our knowledge of these pigments.

A survey of tegumentary colouring is essentially completed by an account of the indole pigments. Apart from the striking Tyrian purple these pigments come mainly under the heading of melanins, a series of ill-defined grey to brown pigments which offer little attraction either as biochromes or as problems for the chemist. However, they play interesting parts in cephalopod inks and as the dark backgrounds essential for the full brilliance of Tyndall blues.

While the preceding pigments are biochromes in the true sense inasmuch as they so often appear to be produced for adornment, others have a more utilitarian role and add little or nothing to external coloration. Of the latter type the most widespread are the tetrapyrroles and in particular the derivatives of hæmatin. It is unfortunate that the introductory chemical survey of these pigments lacks the conciseness of the rest of the book. No elementary account of hæmatin compounds is possible unless the underlying significance of the ferrous-ferri relationships and the distinctive properties of derivatives at the two levels of oxidation are made clear. Such a statement as "the older, rather indefinite term hæmatin is approximately equivalent to hæm" obscures the whole basis of these relationships. Furthermore, the statement that the "exact function [of the cytochromes] in the organism remains yet to be described" completely contradicts the extensive and precise information now available on their respiratory function.

Shorter chapters provide useful summaries on chromolipoids, quinones, anthocyanins, flavones, purines, pterins and flavins. The latter group scarcely qualify as biochromes, their interest being

purely metabolic. However, it would be desirable even in so short a chapter to refer also to flavins other than riboflavin and to flavoproteins additional to the 'old' yellow enzyme of Warburg which is now of little more than historic interest.

The value of the extensive bibliography is greatly enhanced by the inclusion of titles of the papers, a convention which could with advantage be made more general.

E. F. HARTREE

ISOTOPIC METHODS IN BIOCHEMISTRY

Isotopic Tracers In Biochemistry and Physiology

By Prof. Jacob Sacks. Pp. vii+883. (London: McGraw-Hill Publishing Company, Ltd., 1953.) 68s.

AS isotopic methods have become increasingly used in biochemical research, so the number of text-books concerned with the applications of isotopes has also increased. This recent addition to the collection discusses the principles underlying the design of tracer experiments and describes many of the results that have been obtained by the application of isotopic methods.

The first six chapters will appeal to many students of this subject as giving a lucid account, with the minimum of mathematical treatment, of the fundamental principles of nuclear physics and the general methods involved in the use and measurement of both radioactive and stable isotopes. The author is throughout concerned to stress that the use of this new technique introduces its own peculiar errors, and that tracer experiments have to be carefully designed, and, possibly more important, that the results have to be very carefully interpreted. *O sic omnes!* Some topics may seem to have been dealt with all too briefly, and there are a few statements which could lead the poorly informed reader to erroneous conclusions, for example, the statement that "the efficiency of Geiger-Müller counters for beta particles is practically 100 per cent". These criticisms are in part met by the references to other books which are given at the end of each chapter, though the reviewer has been struck by the trans-Atlantic nature of these general references. Without exception they are references to American-published books, and almost without exception the authors are themselves American investigators.

The second and major part of the book, consisting of ten chapters, leaves one much more doubtful as to its general usefulness. These chapters, which are almost entirely biochemical, describe the experimental results which have been obtained in the main fields of biological research using isotopic tracer methods. There is a great deal of information here and it must have cost the author much energy to collect it; but if the purpose of this section is to show by selected examples how tracers have been applied in particular cases and how the results have been interpreted, then all the material presented here is not necessary. Furthermore, since the material is divided into chapters dealing with carbohydrate metabolism, protein metabolism, lipid metabolism, etc., there is a tendency to assume that one is being given a complete account of the development of the field, though of course no mention is made of the not inconsiderable advances which have been made in biochemical knowledge without the use of

isotopes. In addition, the work described here is again drawn almost entirely from American sources, and one is in fact being given an account of the main contributions by American biochemists and physiologists which have involved isotopic methods. This may be justified in a history of American biology; but one doubts its necessity in this particular book. Nevertheless, the material presented is described with masterly clarity, and if its limitations are realized, is well worth reading for its own sake. It should also be said, in all fairness, that two of the chapters in this second section of the book, namely, Chapter 7 on the movement of ions across boundaries and Chapter 16 on photosynthesis, are exempted from some of the criticisms given above, since in these subjects the major advances have been made only since the availability of tracer methods.

Prof. Sacks has written a book which is in many ways a useful addition to the literature of what his countrymen like to call 'tracerology'; but one cannot help feeling that his contribution would have been more generally useful and welcome if the first six chapters had been extended to, say, twelve chapters at the expense of the remaining ten.

The book as a whole seems to be remarkably free from errors and misprints, and the publishers are to be congratulated on the quality of the printing, paper and binding.

WILLIAM C. HUTCHISON

THE PSYCHOLOGY OF PERSONALITY

The Structure of Human Personality

By H. J. Eysenck. (Methuen's Manuals of Modern Psychology.) Pp. xix+348. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1953.) 37s. 6d. net.

DR. EYSENCK of the Maudsley Hospital, London, is already well known for two major contributions to the literature of personality, "Dimensions of Personality" (1947) and "The Scientific Study of Personality" (1952). Although these books owed much, and contained numerous references, to the work of others, they were primarily concerned with giving an account of the investigations carried out by Eysenck and his associates. The present book, on the other hand, is a systematic and critical account of the field as a whole in which Eysenck's own work and its conclusions, though of course they colour his general treatment, are explicitly mentioned only in their appropriate contexts. It is, therefore, the complement of its two predecessors. Taken together the three books are a vigorous and important, if controversial, contribution to contemporary psychology.

Since the publication of Allport's "Personality" (1937) there has been a growing recognition that personality is perhaps the most appropriate integrating concept in psychology. It is defined by Eysenck in the present book as "the more or less stable and enduring organization of a person's character, temperament, intellect and physique, which determines his unique adjustment to the environment" (p. 2). The concept of personality is not only of importance in psychiatry and in most of the applied fields of psychology, but also, as recent work has shown, in many laboratory investigations into apparently quite narrowly specific topics. There is much less agree-

ment, however, as to how this highly complex organization is to be studied. In the controversies which centre around this issue Eysenck is a protagonist. There are no half-measures about his point of view; he is wholly with those who believe in an analytical, mathematical and formally correct scientific approach; he is wholly against all that is untestable, qualitative, verbal, and 'holistic'. He believes not only that personality ought to be studied by the same objective methods as are used in the physical sciences, but also that it can now effectively be so studied. He looks ultimately for "the construction of a mathematical model of personality organization, and the derivation of testable hypotheses from this model by means of the hypothetico-deductive method" (p. 322).

In its approach to this ideal Eysenck's work stems chiefly from the 'London school', of which the main theoretical framework, deriving from Sully, McDougall and Burt, is that of hierarchical structure, and the principal technique, deriving from the psychometric investigations of Galton, Pearson, Spearman and others, that of factor analysis. The present work is indeed entirely devoted to a survey of the numerous factor analytic studies of personality which have been carried out mainly in Great Britain and America. No other line of work receives any serious mention, not because Eysenck is unaware of the existence of this work, but because he believes it to be of small value until factor analysis has established the basic dimensions, or taxonomy, of personality. Within the strict limits imposed by its author's point of view there can be no doubt that "The Structure of Personality" is an important book. It is not only valuable as a work of reference to many tedious investigations, it also contains a good deal of critical comment, to which all those who propose to employ factor analysis must seriously attend. For one thing at least is certain: if factorial methods are to be used at all, they must be used proficiently. Eysenck's insistence on high standards of technical competence is wholly praiseworthy.

The main doubts concern the foundations of the enterprise, and these unfortunately Eysenck does little to remove. The results which factor analysis has so far yielded in the field of personality are not sufficiently compelling to remove these doubts and to command general acceptance. These doubts not only concern the adequacy of the tests and assessments upon which the elaborate statistical structure of factor analysis is erected, but more fundamentally the adequacy of the theory of traits to serve as the firm basis of an exact science. This theory bears a suspicious resemblance to the ancient doctrine of primary qualities which so long impeded the development of the physical sciences, and it may be more than a coincidence that modern typologies, including that favoured by Eysenck, so closely resemble the classical theory of temperaments which was directly derived from that ancient doctrine. If, as is not improbable, the theory of traits is a completely false road in the study of personality, the whole factorial edifice which Eysenck and others have erected collapses. Eysenck in his enthusiasm for scientific methodology appears to forget that no methodological finesse can avail unless the right questions are being asked; and to ask the right questions often requires, as Butterfield put it in his "Origins of Modern Science" (1949), "a different kind of thinking-*cap*". Gardner Murphy in his "Personality" (1947) was perhaps aware of this when he wrote, "Neither in content, nor in method can we be said to have solved the essential problem

of the starting point from which a psychology—any kind of psychology, including a psychology of personality—could be written. . . . We shall rectify mistakes not primarily by the minor readjustments of the lines of the argument, but by recognition of the fundamental limitations of the whole present system of conceptions". Perhaps Eysenck would not wholly disagree with a statement such as this, for he more than once implies that factorial studies are provisional only, until more solid methods are available to take their place. Whether even as a provisional method their value is as great as Eysenck believes, or whether other less precise methods deserve the total rejection which Eysenck accords them, time will no doubt show.

L. S. HARNSHAW

THE PSYCHOLOGY OF SPECTRES

Apparitions

By G. N. M. Tyrrell. Revised edition. Pp. 172. (London: Gerald Duckworth and Co., Ltd., 1953.) 12s. 6d.

THIS book, the first edition of which was reviewed in *Nature* in July 1943, is a revised version of the seventh Frederic W. H. Myers Memorial Lecture which was delivered by Mr. Tyrrell in October 1942. Since that date the theory that Mr. Tyrrell then put forward has met with a growing interest, and in the present volume Prof. H. H. Price, in an admirable introduction, gives it as his opinion that the book is probably the best of all the late Mr. Tyrrell's contributions to psychical research.

Dismissing the physical theories of apparitions as almost wholly unpromising, Mr. Tyrrell turns to those of a psychological nature. To him, apparitions are hallucinations of a particular and very interesting kind, and he divides them into four main classes which, however, cannot be very sharply differentiated. These four classes are: (1) Experimental cases, in which the agent tries to make an apparition visible to a particular percipient. (2) Cases in which a recognized apparition is seen, heard or felt at a time when the person represented by the apparition is undergoing some crisis such as a moment of danger or even death. (3) Cases in which a recognized apparition is seen or heard so long after death or after some crisis that no coincidence can be supposed. (4) Cases of alleged haunted localities in which apparitions are said occasionally to be observed. Cutting across these cases there are a number of characteristics which are common in a greater or lesser degree to all four classes. Moreover, these characteristics, which are of constant occurrence in the statements of the various witnesses, suggest that, in the majority of cases, the accounts are not merely the inventions of imaginative persons, but that they describe actual incidents which have occurred within the experience of the percipients.

One of the main features of Mr. Tyrrell's theory is what he terms the 'idea-pattern', which is the dramatic production of the agent's idea, the apparition itself being the sensory expression of the idea-pattern. It is in no sense a substantival entity but rather the creative product of substantival constituents belonging to one or more personalities. Thus what is perceived as a full-blown hallucination is merely the outward expression of a drama; and it is within this drama that elements can be detected which may be able to throw considerable light upon the deeper

strata of human personality and the remarkable power of subconscious activity.

In developing his thesis Mr. Tyrrell is careful to avoid any extravagant suggestions. He relies for his facts upon the best cases to be found in the literature, especially those published in "Phantasms of the Living" and in the *Journal and Proceedings of the Society for Psychical Research*. How far these accounts can be relied upon is for the reader himself to decide. More than sixty years ago Mr. A. T. Innes, in a discussion of "Phantasms of the Living" (1886), pointed out that contemporary letters and documents proving the authenticity of the crisis cases were conspicuous by their absence, and he went so far as to state that of seven hundred miscellaneous cases which he had examined one only was accompanied by a relevant document.

Although perhaps it might have been wiser in this edition to warn the reader regarding the weakness of many of the examples quoted and to have recorded the gist of the Innes-Peirce-Gurney controversies, the book remains the best critical discussion of apparitions that has hitherto appeared. It sweeps away many of the misconceptions so common when discussing 'ghosts', and brings the whole subject into sober perspective so that these very curious phenomena can be fitted (at least partially) into the psychological framework where they undoubtedly belong.

E. J. DINGWALL

LOGIC FOR MODERN SCIENCE

The Logic of Modern Science

By Prof. J. R. Kantor. Pp. xvi + 360. (Bloomington, Indiana: The Principia Press, Inc., 1953.) 6 dollars.

THE principal thesis of this book appears to be that scientific procedures and results have been too much and too unwittingly influenced by cultural institutions. The author, who is a psychologist, therefore proposes to reject all current ontological, epistemological and psychological theories concerning natural science, for these all suffer from the defect of involving what the author calls mentalistic and spiritistic notions which have been introduced not in the interest of science but of theology. But he goes even further than this: he not only rejects Berkeley but also Hume. He wishes, apparently, to reinstate naïve realism in epistemology and to retain a thing-attributed theory in ontology. His psychological theory is his own and is called interbehaviourism to distinguish it from ordinary behaviourism which he rejects. He calls the latter "the end point in the dualistic development we have just sketched". The psychological organism becomes the *body without mind*. The behaviourists, for example, simply deny the necessity of dealing with any psychic factor. The strict behaviourist attempts to interpret all psychic happenings in terms of the operation of the brain and other nervous structures.

"But has the behaviorist disposed of 'mind'? Hardly. He simply throws away one half of the traditional body-mind construction and builds his system on the remainder. In no sense does he extricate himself from the dualistic tradition. What is required is to withdraw completely from historical constructions. We need to start over again. *Inter-behavioral* psychology . . . makes this attempt" (p. 259).

The present reviewer confesses that he has failed to understand interbehavioural psychology from what the author says in this book. Perhaps it is necessary to read the same author's other books on the subject. The most easily understood parts of the present work are naturally the critical parts. These have much that is interesting to say about physics, chemistry, biology, psychology and sociology. After such wholesale destruction anything constructive is bound to be so novel and revolutionary as to be extremely difficult to follow. This difficulty is increased in the present instance by the author's rather loose use of language and the absence of detailed argument showing how the new view overcomes the difficulties with which the older theories attempted to deal.

The word 'logic' is used throughout in a very wide sense, and the few remarks which the author makes about logic in the narrower and stricter sense are rather misleading. Consequently, when the author comes to discuss such questions as: "What is the significance of abstract formal systems for scientific work?" and: "Are scientific laws deduced from the premises of logical systems or constructed from events?" his treatment of these topics (which require a knowledge of logic in the narrower sense) is intuitive and popular rather than analytical and scientific. No mention is made in the extensive bibliography of the work of Carnap, Church, Quine or Tarski among the many who have contributed to these topics in recent years. Similarly, the chapter on mathematics and natural science, which makes no reference to the work of Frege, Whitehead and Russell, Hilbert or Brouwer, scarcely rises above the popular level and gives a very misleading notion of the present state of knowledge.

J. H. WOODGER

VERMUYDEN AND THE FENS

Vermuyden and the Fens

A Study of Sir Cornelius Vermuyden and the Great Level. By L. E. Harris. Pp. 168+8 plates. (London: Cleaver-Hume Press, Ltd., 1953.) 21s. net.

THE draining of the Fenland is one of the most notable enterprises in the history of the English countryside. It was achieved only with much difficulty, and the main architect of that achievement was Cornelius Vermuyden. He was born in 1590 on the island of Tholen in Holland, and moved to England in 1621. He was involved in a number of enterprises; but the greatest, and the one upon which his reputation must rest, was the draining of the great stretch of peat later known as the Bedford Level.

During the latter years of the sixteenth and the early years of the seventeenth century, the possibility of draining this area was hotly debated, and the debate culminated in 1630 in a project headed by Francis, fourth Earl of Bedford. Vermuyden was already interested in the scheme, and, at the request of the Earl, he undertook the direction of the work. Discussion had ranged around two opinions. One held that the existing watercourses should be deepened and embanked; the other, held by Vermuyden, advocated that new and artificial straight cuts be made. So it was in accordance with this second view that the work proceeded. The confusion of the Civil War, and continued hostility to the scheme, interrupted the progress of the work, and it was not

until 1652 that the area was formally declared to be drained. Vermuyden's connexion with the Level appears to have ceased in 1655; and but little is known of his life after this. The date of his death was in doubt, but Mr. Harris has now shown that it was 1677; the record of the burial is in the register of the Church of St. Margaret, Westminster.

The work of Vermuyden, both while it was in progress and afterwards, was surrounded by controversy, and it is true that successive floods, more than once, very nearly brought the scheme to disaster. As one engineer, John Golborne, wrote in 1777: "Look which way you will, you will see nothing but misery and desolation". Neither Vermuyden nor his associates apparently had realized that as soon as the peat was drained, its surface would become lower, and that pumping would be necessary. It is this lowering that has very largely been responsible for the continued flooding of the Fens. Successive engineers bitterly attacked Vermuyden's engineering works on technical grounds, and Mr. Harris guides us with great skill through the many differences of opinion. Moreover, he points out that "the only practical standard of comparison to apply to Vermuyden's work is how the drainage of the Great Level would be carried out to-day, assuming that conditions in, and the state of, the Level were as they existed in the mid-seventeenth century. Would a similar plan be adopted?" It is a difficult question to answer; but the fact is that the new Flood Relief Scheme embodies features that Vermuyden proposed but which were never carried out. Had these been carried out, "his scheme would have proved even more successful than in fact it did". The general professional verdict on Vermuyden's work has "become more favourable", and something of his greatness appreciated.

Amid this story, some light is shed upon Vermuyden himself. He was "a hard man of business", both "dominating and aggressive", certainly litigious. "It is debatable whether Vermuyden could be considered to have been a likeable man." But in making these remarks, Mr. Harris would have us remember that the bitter criticism of his work was certainly unjustified, and that there is no "valid reason why the judgement of success should be withheld from him".

This book not only throws light upon a little-known figure of the seventeenth century, but also is of the first importance to any student of fen draining. It most skilfully handles difficult material, and presents a balanced picture of a man and a problem. It is also attractively written and attractively produced and illustrated.

H. C. DARBY

ORIGIN OF METAMORPHIC ROCKS

The Origin of Metamorphic and Metasomatic Rocks A Treatise on Recrystallization and Replacement in the Earth's Crust. By Prof. Hans Ramberg. Pp. xvii+317. (Chicago: University of Chicago Press; London: Cambridge University Press, 1952.) 75s. net.

THIS interesting book is the latest of several texts, dealing with the origin and formation of crystalline rocks, that have appeared in recent years in the United States. Prof. Ramberg confines himself to the field of metamorphism, though this is viewed

in the broadest terms so that such operations as granitization are included. The sub-title indicates the author's respect for metasomatism as a rock-forming process, a subject with which the last third of the book is largely concerned.

In his opening discussion of some of the principles of thermodynamics and crystal chemistry, Prof. Ramberg bases his analysis of chemical processes in rocks on the concept of free energy. He argues that this is simpler than a discussion of the relations of minerals with a hypothetical pore fluid. He makes a most interesting attempt to compile equilibrium diagrams for metamorphic minerals largely from the data provided by mineral assemblages in the different metamorphic facies. It is considered that such diagrams, even though calculated theoretically from an insufficient number of points, provide the best way we have of presenting the scanty data available on the behaviour of metamorphic minerals under changing pressure-temperature-concentration conditions. The tentative nature of these diagrams is repeatedly pointed out and, provided this is borne in mind, a very promising method of dealing with metamorphic assemblages seems to be developed. An appendix on chemical bonds in crystals is provided as a supplement to these early chapters.

A discussion of the kinetics of metamorphism leads on to the more strictly petrological parts of this book. These make up about two-thirds of the text, and may well, as the author points out, be read first. Here emphasis is put upon the general principles of petrogenesis, while the "collection of erratic data and descriptions of rocks or field relations are kept at a minimum". This quite justifiable treatment requires that the reader must have a general acquaintance with metamorphic rocks. Such a treatment does not mean that field evidence is neglected. On the contrary, one of the most attractive features of the work is the attention paid to what might be called the architecture of the extensive regionally metamorphosed terranes. This is shown in the survey of structural properties of metamorphic rocks and again when the deep-seated quartz-feldspathic rocks are described during the discussion of metasomatism. These sections are illustrated by excellent photographs, most of which were taken by the author during his work in Greenland.

After a short discussion of stress and antistress minerals and the structural survey mentioned already, there comes an account of the mineral facies of metamorphic rocks, with emphasis on the assemblages formed during regional metamorphism (twenty-seven pages) as against those formed during contact metamorphism (two pages). This emphasis is maintained in the treatment of metasomatism and metamorphic differentiation and is no doubt deliberate, for the author is concerned to show the prime importance of regional metamorphism and metasomatism as rock-forming operations.

Metasomatism is recognized as a complex and little understood process. If we accept the author's view that this process is not one in which we can "expect to receive aid from physics and chemistry in the form of laws ready to be applied to our complex problem without many modifications", the lengthy discussion of transfer of matter through rocks must at times seem rather speculative. But unless geologists with the experience of Prof. Ramberg are prepared to expose their views on the subject, we may never get to grips with the question. This discussion is followed by an account of metamorphic differen-

tiation, after which there is the briefest of references to contact metasomatism (twenty lines) and a very relevant excursion into metasomatism in practically unmetamorphosed sediments. It is a pity that these last two topics could not have been treated more fully, for an understanding of such matters would contribute to our comprehension of the regionally metamorphosed schists and quartz-feldspathic gneisses which constitute the major problem. Whether or not one agrees that such rocks are the product of diffusion through the solid, the author must be given credit for setting out so clearly the facts about the occurrence of such rocks in the deeply eroded mountain chains, facts which any hypothesis on deep-seated plutonism must take into account.

H. H. READ

GENETIC CLASSIFICATION IN MINERALOGY

Spezielle Mineralogie auf geochemischer Grundlage Mit einem Anhang: Ein kristallchemisches Mineralsystem. Von Prof. Felix Machatschki. Pp. vii + 378. (Wien: Springer-Verlag, 1953.) 61s. 6d.

ALMOST all text-books on mineralogy have been based on a chemical classification more or less modified by structural considerations; the first subdivision has been into elements, sulphides, oxides, carbonates, silicates, etc., while within each of these divisions the big isomorphous groups of species, such as the rhombohedral carbonates, the feldspars, or the spinels, form natural units. More recently, the developments of structural crystallography have allowed an intermediate division by structurally allied groups such as the island, chain, sheet, and network silicates.

Prof. Machatschki has experimented with a quite distinct method of classification—a genetic one. Followed strictly, this approach would lead to the dispersal of many familiar groups of structurally and chemically allied species such as the pyroxenes; this and other considerations have deterred him from following his idea to its logical conclusion, and some readers may feel that this division of aim detracts from the unity of the book. But all should find the novel approach stimulating, and the book should prove a very valuable addition to the bookshelf of mineralogists and petrologists alike. It is difficult to decide at a first reading how far the divided aim will prove of serious detriment; but of the value of many features of the book there can be no doubt.

After a short introduction Prof. Machatschki deals with the primary magmatic minerals in order of crystallization, then with pegmatitic-pneumatolytic, hydrothermal, and solfataric minerals. The second section deals with clays, lateritic minerals, and other weathering products, evaporites, and minerals of organic origin, and the third with the minerals of metamorphic rocks. A great many minerals would fall into more than one of these headings and many familiar mineral families would be scattered over several headings; so each well-known family is discussed in detail at the earliest point in this genetic development where any member of the family is encountered. The ore minerals are treated exceptionally; instead of being dealt with as they are met in the logical genetic series, their detailed descriptions are all collected in a special section, arranged

under metals, with particular attention to the rarer metals. A rather similar and very useful arrangement is adopted for the pegmatitic-pneumatolytic minerals, which are divided into lithium, rubidium-caesium, beryllium, boron, etc., minerals.

As an appendix, a strictly crystallochemical classification is attempted, which may be of value in disclosing some unexpected structural similarities.

The chemical formulae for the species are a feature to which Prof. Machatschki has given special attention. He indicates the co-ordination of the principal atoms or groups by bracketed superscript numbers (for example, $\text{Si}^{(4)}$, $\text{Al}^{(4)}$), and encloses polyatomic anions with homopolar or largely homopolar links in square brackets (for example, $[\text{SO}_4]$, $[(\text{Si}, \text{Al})\text{O}_4]$); structures based on homopolar-linked chains, sheets, or networks are prefixed ∞^1 , ∞^2 , and ∞^3 respectively, while the chemical formula is followed by a letter or pair of letters symbolizing the system of crystallization. These features should prove very useful in giving a condensed picture of the principal structural features.

There are few errors or omissions of consequence, though some rare minerals are unexpectedly included and more common ones omitted (for example, the very rare edingtonite is included, and incorrectly stated to be related to scolecite, while the much commoner mordenite is omitted; and mesolite is a definite compound, not a mixed-crystal).

M. H. HEY

CLAY MINERALS

Clay Mineralogy

By Prof. Ralph E. Grim. (McGraw-Hill Series in Geology.) Pp. xli+384. (London: McGraw-Hill Publishing Company, 1953.) 6s. 6d.

THE extent of the interest in clay minerals is very wide, as Prof. Grim points out in the introduction to his excellent book, ranging as it does from the earliest of human industries—pottery making and agriculture—down to the cracking of oils in modern refineries. Physical and physicochemical studies carried out by many workers over the past hundred years had provided a considerable insight into the properties of clays; but it was not until Hadding's discovery of their crystallinity that a more fundamental attack on the subject was possible. The adumbration by Goldschmidt and Pauling of the laws of crystal chemistry and their application by C. E. Marshall to minerals like montmorillonite made further advances possible. While much has been learned about clay minerals in the relatively pure state, much remains to be done on the complex mixtures that occur in such materials as soils and sediments. The quantitative aspects of such mixtures still bristle with difficulties that will not easily be overcome.

As in other aspects of mineralogy, misidentification and duplication of names has proved troublesome; but in his discussion of this Prof. Grim surely goes too far in relegating beidellite to the ranks of discredited species. Attapulgate would be a more appropriate candidate, for all the evidence points to the identity of this and palygorskite, which has a very long-standing priority. Recent work has certainly shown the advisability of checking all identifications by X-rays, otherwise much work can be completely vitiated.

Appropriately, the main part of the book begins with a good account of the structures of the various clay minerals, with tabulated data taken largely from the Clay Mineral Group's monograph. The latter will, however, still be essential to anyone wishing to use X-ray techniques, for in a general text it is obviously impossible to cover every aspect of the work and discuss the many difficulties that arise in the interpretation of X-ray diffraction patterns of clay materials.

Successive chapters then deal with electron micrograph studies on shape and size, and with ion exchange. In this last Prof. Grim seems out of his element, but it is an adequate account. In marked contrast are the chapters on the clay-water system and the effect of heating on clays, in which the author is dealing with aspects to which he has contributed much, and both are very thoroughly treated. Reactions with organic substances, which come next, have proved extremely valuable both in connexion with the properties of the clay minerals and their identification, but also in opening up the possibility of studying the organic molecules taking part. This has obvious bearings on the reactions between soil organic matter and clays and in particular the apparent inactivation of certain types of substances with regard to biological decomposition. Chapters on the optical properties of clay minerals and miscellaneous properties (solubility, infra-red spectra, etc.) complete what one might call the laboratory side. In the last two chapters Prof. Grim deals very thoroughly with the origin and formation of clay minerals as far as the data will allow. Many more field data are required before one can obtain a clear picture of clay mineral formation in many cases. One would have hoped that something like an 'inverse' Bowen reaction series might have held good for the natural synthesis of clay minerals, but there seem to be too many exceptions.

In a book covering such a broad field it would be easy to find fault on particular points, especially since the subject is developing so rapidly. The book is well documented both in footnotes and supplementary bibliographies in each chapter, and it can be thoroughly recommended.

A. MURR

GEOLOGY AND SCENERY

Geology and Scenery in Britain

By T. G. Miller. Pp. 224+31 plates. (London: B. T. Batsford, Ltd., 1953.) 18s. net.

IN writing a work dealing with the correlation between the geological make-up and scenery of Britain, the author has chosen to enter a highly competitive field of geological literature. Personally, I doubt the need for any further addition to it, unless the aim is to go beyond and into the dependence upon the outward expression of the rocky skeleton of the country of the organic population and its manifold activities. Were such a subject the main theme of this book, it might well claim some novelty, and indeed in the introduction we are promised more of this than eventually materializes. The author sets out to produce a compromise between the 'country book' and the technical regional survey, the whole to be comprehensible to the layman with a love of the countryside. The balance is far from lying midway between the two and in fact lies heavily towards the

regional survey, in which case it becomes justifiable to compare it with similar productions. It also appears that Britain comprises England and Wales only, so that the scope of the book becomes identical with Sir Arthur Trueman's "Geology and Scenery in England and Wales". Since the latter is available for half-a-crown, Mr. Miller sets himself a task of no inconsiderable magnitude in crashing into the market.

On the whole he has produced a readable volume and in places displays astonishing lucidity. What is said is said in a concise manner, and most geologists would appreciate the deftness with which the author disposes of masses of detail; but I think that the layman would appreciate a sacrifice of some of the subject-matter and a fuller, if more cumbersome, exposition of a well-selected residuum. Mr. Miller has used this technique in his useful diagrams. Why not in the text? The pithiness of certain sections of the early chapters dealing with the fundamental principles of geological science is admirable, but there is a tendency for certain short asides and summaries to miss the point in an irritating manner. This phenomenon of just missing the target applies also to some of the quotations used as chapter headings. Thus I do not think that the conflict between Man and Nature can be summed up as "dubious neutrality" (p. 22) on the part of the former, or that a quotation involving "the mountains far away" (p. 73) is an appropriate introduction to a chapter on the older rocks of Wales. Bacon's conception of the earth (p. 19) does not harmonize with the geologist's approach and stands in marked contrast to the subject-matter of the chapter which it introduces. If quotations are not apt they ought not to be used.

The volume includes some very fine plates illustrating scenery and structures. One might protest against foreign views being included in a work on British scenery were it not for the fact that they are among the best in the book. The Persian photographs especially are wonderful. The references to Plate 30 on page 76 and to Plate 31 on page 81 should be interchanged.

The author has produced a painstaking review of his subject; he can write well and I am glad to have his work on my shelves. Even so, if one is limited to a single volume on this topic, there are better works already available. FRANK HODSON

THE EARLY DAYS OF AGRICULTURE

Plough and Pasture

The Early History of Farming. Part 1: Prehistoric Farming of Europe and the Near East. By E. Cecil Curwen. Part 2: Farming of Non-European Peoples. By Gudmund Hatt. Pp. xii+329+14 plates. (New York: Henry Schuman, Inc., 1953.) 5 dollars.

AGRICULTURE has been practised for some six or seven thousand years; but its written records go back for only about one-third of this time. Fortunately, modern archaeologists have been able to unravel a great deal of the earlier history and it is now possible to draw up a much more extensive account than was practicable a generation ago.

Mr. Curwen and Prof. Hatt have summarized much of this new knowledge, but instead of writing one book jointly Mr. Curwen has in one section described the prehistoric farming of Europe and the Near East, while in the other section Prof. Hatt deals with the farming of non-European countries.

Mr. Curwen, who is already well known for his writings on Sussex archaeology, starts with the primitive food-gathering stage of human history, and shows how the gradual drying of the climate in the eastern Mediterranean and Near East curtailed the range of operations. Mankind then split into two groups. One tended to settle in the river valleys and well-watered oases where its members cultivated some of the wild grasses; the other group remained nomadic but could no longer rely on hunting and food gathering; instead they domesticated certain animals and became pastoralists, wandering from one set of grazing lands to another, at first indiscriminately, but later kept to a regular sequence of dry and wet season pastures, each tribe having its own particular lands. Gradually the settled agriculturists developed the arts of civilization, the sciences and the practical activities: they became inventors, traders and ultimately industrialists; the pastoral peoples on the other hand tended to become more contemplative and developed religions, poetry and the mystical arts. Mr. Curwen shows how the ancient traditions of Egypt, Greece, and Palestine as expressed in the Old Testament agree in placing the origin of this dichotomy of races in an area bounded on the west by the river Nile, on the east by the river Indus, and on the north by about the forty-fifth parallel. The period in time was the end of the Mesolithic and the beginning of the Neolithic age.

The early history of the cultivated cereals, the domesticated animals and the implements is given in some detail; the account of the plough, however, should be read in conjunction with F. G. Payne's studies on this subject. It is remarkable that the number of kinds of plants and animals used as food has decreased since the early food-gathering days and that very few additions have been made to the list of common foods with the exception of migrants such as potatoes and maize, which, however, had been used from very early times in their respective countries of origin.

English readers will welcome the opportunity of reading the account by Prof. Gudmund Hatt, of the University of Copenhagen, of the development of agriculture in countries outside Europe and the Middle East. He begins with accounts of food gathering in the Americas, Australia and Africa, and describes some of the protective magic associated with it. The "symbiosis between man and plants" and the "religious fear of wronging the food plant", to quote the author's phrases, gradually developed into agriculture which doubtless originated independently in the different continents, for the human migrations had taken place long before it occurred. The earliest stage was a combination of hunting by the man and a rudimentary agriculture practised by the women using digging sticks. This semi-agriculture gradually developed into full agriculture using implements drawn by animals directed by men. Roots—yams, cassava and others—played a larger part than in Europe; maize seems to have come late into North America. The Kentucky caves give evidence of the cultivation of sunflowers, goosefoot (*Thenopodium*), a pumpkin (*Cucurbita pepo*) and a gourd (*Lagenaria siceraria*) long before pottery was known or maize or

beans grown: curiously enough the gourd seems to have been of Old World origin. Tobacco culture was widespread in America even among tribes that did not grow food. It is unknown whence or how maize came into cultivation, but its arrival was a turning point in American history, for it made possible the magnificent cultural evolution in the Andes and in Central America, Mexico and the south-west area. Wherever it came from, Colombia appears to be its oldest centre of cultivation. Colombia also appears as the centre of origin of a number of other cultivated plants.

The book contains a large amount of information that will be new to many readers and which, moreover, is not generally accessible. It can be commended to all who are interested in the origins and early history of our domesticated animals and field crops, and in the tools men used for dealing with them.

E. JOHN RUSSELL

THE SOILS OF EUROPE

The Soils of Europe

Illustrated Diagnosis and Systematics. By Prof. Dr. Walter L. Kubiëna. Pp. 318+26 plates. (Madrid: Consejo Superior de Investigaciones Científicas; London: Thomas Murby and Co., 1953.) n.p.

UNTIL the identity of a creature can be established and communicated, correlation and the transfer of experience are impossible and knowledge remains chaotic. The recognition and precise description of kinds of plants and animals by such men as Turner and Geener in the sixteenth century provided the essential foundation for modern biological science; and as a pedologist Dr. Kubiëna is surely right in asserting the urgency of his aim in this book, which "is an attempt to make it possible to identify and to give suitable names to soils for all who need it". Descriptions of 173 different "formations of soils" are illustrated by more than fifty excellent reproductions of beautifully executed paintings chosen in preference to photographs to emphasize the features regarded as most significant. Keys are provided to facilitate rapid identifications which may then be checked by the more-or-less detailed profile descriptions. Many synonyms are carefully equated in the explanation of more than four hundred soil names and some two hundred pedological terms. Dr. Kubiëna claims to have studied personally most of the soils described, and it may well be doubted if any other person could provide such an extensive background of personal experience. It is a pity that in this translation from the German such a valuable book should be marred by English so often ambiguous that the reader is left doubting those subtleties which may well have been intended; and from the number of typographic errors it seems doubtful whether the proofs could ever have been read at all.

The development of a precise terminology, a clear and concise nomenclature, and an orderly and serviceable classification are probably the three most urgent requirements in the study of the soil. In the field of profile description Dr. Kubiëna is particularly helpful in those features of the profile which reveal themselves best under the microscope. His account of both the morphology and genesis of the various forms of organic matter establishes without question the value of his techniques, while the features upon

which he bases his important distinction between *Lohm* and *Erde* could scarcely be fully discerned by the unaided senses. Many of the profile descriptions, however, are quite inadequate for precise diagnosis, and some of the more obvious features, such as major profile structures, for example, are often not described at all.

In nomenclature, Dr. Kubiëna adopts a Linnæan approach, and perhaps assumes too readily that the success of a system for plants and animals is a guarantee of its value in soils. Indeed, in his assumption that soils may be "as exactly and unambiguously characterized and named as breeds of cereals, market garden crops, and domestic animals" Dr. Kubiëna is assuming an analogy which is misleading. Plants and animals are discrete and transferable units with their essential characters determined by an internal mechanism, whereas soils, as Dokuchaiev insisted, "are a mere function of the soil-forming factors". As in petrology, the essential problem is the significant division of a gradually varying continuum, and it may be that a premature enthusiasm for "pigeon-holing" may divert energies from the more vital study of soil and landscape relationships. That Dr. Kubiëna is himself aware of the merging of soil boundaries is clear from his emphasis on the strongly dynamic nature of soil profiles; and his evolutionary division between raw soils, ranker soils, and more mature soils recognizes, at a high level in his classification, profile development sequences similar to those which have been shown to be of such practical value in New Zealand. To arrange soils in order from the simplest to the most complex, after consideration of "all essential characteristics", is a logical aim, but its adequate fulfilment will require much more knowledge of profile dynamics than we now possess.

The book is stimulating and of lasting value, and cannot be neglected by any serious student of the soil.

E. CROMPTON

ELECTRONIC THEORY OF VALENCY IN ORGANIC CHEMISTRY

Electron Structures of Organic Molecules

By Prof. Lloyd N. Ferguson. Pp. xi+335. (London: Constable and Co., Ltd., 1952.) 48s. net.

THE scope of this book is correctly described in its title. As is explained in the introductory chapter, it gives an up-to-date account of that part of physical organic chemistry which is concerned with molecules in their normal (non-reacting) states. Successive chapters carry the following headings: the types of chemical bonds, the polar nature of covalent bonds, covalent bond distances and bond angles, intramolecular forces, induction and electric dipole moments, magnetic susceptibility, resonance and its applications in organic chemistry, absorption spectroscopy (this chapter and the preceding one occupy almost half the book), aromatic substitution, and molecular and electron structures by physical methods.

The treatment is clear and the expositions generally full, so that the book is interesting to read and should be easily followed by the honours degree student for whom it seems to have been designed. Yet a conscientious teacher might hesitate before recommending the book without qualification—especially as it is so expensive.

Misprints occur in all books, and in this one not oftener than the average; but the erroneous formula for picryl iodide on p. 174 and the mistake in equation (8) on p. 220 are examples of rather serious slips. What is much more serious is that the writing abounds in loose phraseology such as, "the four valencies of a carbon atom form a tetrahedron" (p. 89), or the "equation ($A = A_{\text{sol}}^+ + e^-$) is the electrode potential" (p. 70). Again, to write of associated compounds on p. 65 that the "association increases the solubility in water" is surely to suggest a false causality. In a single paragraph on p. 80 the phrase "degree of association" is used in two distinctly different senses. Furthermore there are some misleading statements: "the chief use (of X-rays) to organic chemists has been with crystalline powders" (p. 82), and "electron diffraction is the principal type of diffraction studies being made now" (p. 83) are opinions that could not long survive a glance at any recent volume of the "Structure Reports". In several places (for example, pp. 22, 144, 159) the expert reader will gain the impression that the molecular orbital treatment is merely a part of the resonance concept, instead of being an alternative and independent method of approximation.

When another American author has written of "the electronic theory of the English school", it is surprising to find the names of Ingold, Lapworth, Robinson and Sidgwick together accounting for only 14 entries in Prof. Ferguson's author-index, while several Californian or mid-Western authorities individually exceed this total. (On the other hand, two well-known American workers appear as "R. B. Core" and "J. Donahue" in both text and index.)

Most of these defects are superficial and could be easily remedied, and to have pointed them out at this length is to have emphasized them unduly unless it is also emphasized that this book has many virtues. A large quantity of current information is brought together in a useful way, and offered in a readable form. Those able to read the book with judgment will find it valuable. After every few pages there is a list of books and review articles for supplementary reading. These lists are up to date and well chosen; and they are by no means confined to American publications. With due safeguards, this book should be made accessible to advanced students of chemistry; it can be recommended to any of their seniors who may be concerned with physical organic chemistry.

J. O. SPEAKMAN

variables are involved and a vast amount of work remains to be done. This has become even more evident since the comparatively recent discovery of the phenomenon of cocatalysis and the fact that the true chain initiators may be complexes between catalyst and trace impurities, solvent, or even monomer.

In this present state of the subject a normal type book would be premature. I believe, however, that Dr. Plesch has succeeded in the present volume in satisfying the intense interest in the subject by producing what is in effect a progress report by the most eminent workers in the field. There is reported here, with copious references to earlier work, a good deal of representative material which has been published in recent years together with some which will shortly appear. Most valuable of all, however, are the comments and suggestions made in discussion. The whole has been arranged, presented, and printed in a most attractive and readable fashion.

After a foreword by Sir Eric Rideal, the preface by Dr. Plesch gives a historical survey and puts the later discussion in perspective by showing in particular the economic and industrial aspects of the subject and also its relationships to modern theories of organic chemistry. Thereafter the book is divided into two main sections approximately equal in length. The first is devoted entirely to papers on complex formation with a direct bearing on the initiation process, while the second includes papers on the polymerization process itself. These are summarized by Prof. D. D. Eley and Prof. F. S. Dainton respectively.

Adverse comment is of a trivial nature and detracts not at all from the value of the book. It is concerned only with minor points of inconsistency in presentation. For example, Ph and C_6H_5 are used, even in the same equation (p. 76), to represent the phenyl group and the appearance in the text sometimes of [] while at other times "the concentration of" is written in full. These points may be rather difficult to avoid, however, in a publication of this nature where the original material has come from a number of authors.

This book gives an authoritative account of the state of our knowledge of cationic polymerization at March 1952. It is of particular value to all interested in the general fields of high polymers and complex formation and must be indispensable to workers in the more restricted field which it covers.

N. GRASSIE

CATIONIC POLYMERIZATION

Cationic Polymerization and Related Complexes

Edited by Dr. P. H. Plesch. (Proceedings of a Conference held at the University College of North Staffordshire, 24th-26th March, 1952.) Pp. xii+166. (Cambridge: W. Heffer and Sons, Ltd., 1953.) 20s.

THE experimental investigation of cationic polymerization was initiated in the early 1930's, as Dr. Plesch points out in his most admirable preface to this book, when it was recognized as a distinct type of polymerization reaction by reason of the fact that it could not be fitted into the general theory of free-radical chain reactions. Since that time, spectacular advances have been made in the understanding of the fundamental nature of the reaction. While a fair measure of agreement on general detail has been reached it is quite clear that a very large number of

TECHNIQUE OF ORGANIC CHEMISTRY

Technique of Organic Chemistry

Vol. 8: Investigation of Rates and Mechanisms of Reactions. S. L. Friess and A. Weissberger (Editors). Pp. xxiii+760. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1953.) 12.50 dollars.

THIS volume surveys the broad domain of chemical kinetics. The editors have sought to present theoretical as well as practical techniques, and topics outside the scope of formal kinetics are treated when relevant to the problems of reaction mechanism. The initial chapters are relatively general and are devoted to the theory of chemical kinetics, to experimental methods of measuring

reaction-rates, and to the principles underlying the elucidation of mechanism: later chapters are more specialized and refer to gas-phase reactions, liquid-phase reactions (and homogeneous catalysis), polymerization and polymer reactions, biological reactions, and very fast reactions. Heterogeneous reactions, heterogeneous catalysis and other bi-phase processes are not treated.

Viewed as a whole this is unquestionably a useful source-book for chemists whose interests lie within or on the fringe of the field of reaction mechanism. The least successful aspects are the purely theoretical parts, for the absolute rate theory which is the natural foundation of the main sections of the book is very summarily presented, the degree of condensation being such that in some respects the foundation is insecure. For example, in the discussion of the effect of isotopic substitution (p. 26) it is claimed that, a C—H bond being replaced by C—D, the *maximum* theoretical ratio of rate constants is 4.3. Actually, the author has calculated (approximately) the 'maximum' velocity ratio for a special, and certainly very rare, case in which the deformation vibrations have the same frequency in the ground and transition states; but none of this is explained. Probably no one will be misled, but it is disturbing to find several references to this 'derivation' at points later in the book.

The field covered in this volume is broad and correspondingly difficult to survey; but the authors have maintained in general a very even and interesting level. In a treatise on the methods of organic chemistry it is natural that liquid systems receive the most attention; but not the least useful sections are devoted to the theory and practice of relatively specialized techniques: for example, flow methods, which are becoming increasingly popular. It may, perhaps, be regretted that the section on rapid reactions is restricted to biochemical systems or to systems primarily of biochemical interest: no account is given of the investigation by ultrasonic and other new methods of simple, very fast reactions in the gas phase.

Binding and presentation conform to the high standard of the series, and a cumulative index to the earlier volumes is provided. J. C. D. BRAND

RUSSIAN PROGRESS IN ELECTRON DIFFRACTION

Electron Diffraction

By Prof. Z. G. Pinsker. Translated by J. A. Spink and E. Feigl. Pp. xiv + 443 + 25 plates. (London: Butterworths Scientific Publications, Ltd., 1953.) 63s. net.

THE appearance of a translation of this important Russian book is very welcome. A specially contributed preface by the author suggests that Russian scientists are anxious for international co-operation, and this would be greatly helped by the appearance of further translations of this kind.

As an orthodox work on the theory and practice of electron diffraction, the book is very good; it deals with the elements of wave theory, the diffraction of waves by crystals, experimental methods, apparatus, and practical results. The chapters on the last subject appear to deal fairly with Russian and non-Russian contributions, and it is evident that, in

some types of electron-diffraction work, the Russians are well ahead. This is particularly true of crystal-structure determination; since electrons are scattered by the field within an atom and not by electron density, hydrogen atoms are more easily detected by electrons than by X-rays, and work on this subject has been appearing in the Russian literature since 1948. As far as the reviewer is aware, the earliest comparable work in English is that of Cowley in Australia, published in 1953.

As a historical commentary, however, the book has several defects. For example, the discovery of electron diffraction is attributed solely to Davisson and Germer, Thomson's work being referred to, only incidentally, several pages later. Quite naturally, Russian work receives predominant attention; but it comes as a shock to find W. L. Bragg given only minor honours for what is usually known as Bragg's law; Prof. Pinsker consistently refers to this law as the Wulff-Bragg law, claiming that it was discovered by "the Russian scientist Wulff (*Phys. Z.*, 14, 217; 1913) and simultaneously Bragg (*Proc. Camb. Phil. Soc.*, 17, 43; 1912)".

This claim deserves some attention, since simultaneity can be claimed only if the later paper were received before the earlier one was published. In this instance, this is not so; Bragg's paper was published in November 1912, and Wulff's was not received until February 1913. Moreover, Wulff's idea arose out of a note published by Bragg in *Nature*, in December 1912, to which Wulff refers in his paper. Thus the claim for a division of the honours cannot be substantiated, even though Wulff was clearly unfortunate in that Bragg's paper was published in a journal which was probably not well known to him.

The translation has been carried out extremely competently, even if the English is inclined to be a little stilted in parts. The translators have added to the value of the book by including many extra references, and the author has contributed some recent Russian ones in his preface.

The book can be confidently recommended as an important work on the subject. H. LIPSON

RADIOACTIVE ISOTOPES

Radioactive Isotopes

An Introduction to their Preparation, Measurement and Use. By W. J. Whitehouse and J. L. Putman. Pp. xvi + 424 + 6 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1953.) 50s. net.

DURING the past decade the number of applications of radioactive isotopes has increased enormously, and the concomitant growth of interest has created a demand for appropriate text-books. For those who wish to read about the preparation of radioactive isotopes, their properties and uses, "Radioactive Isotopes" constitutes an excellent survey. The treatment is comprehensive and well balanced and the presentation generally lucid and precise: furthermore, the book arouses and maintains interest.

After a brief survey of the nuclear reactions which are used in the production of radioactive isotopes, the modes of nuclear disintegration are discussed together with the properties of the radiations. These topics occupy about a quarter of the book and they constitute the background for the remainder of the text. The authors then deal with the practical

production of isotopes in uranium piles and cyclotrons, and the reader is given a clear description of the requirements for these processes. More stress might have been laid, however, on the high specific activities produced by the Sillard-Chalmers effect.

The chapter on the detection and measurement of the radiations includes sections on units, Geiger counters of various types, proportional and scintillation counters. Absolute and relative counting are both considered and a section is devoted to the statistics of counting experiments. Adequate reference is made, for example, to the comparison of radioactive sources under exactly similar conditions. It is a pity that occasionally one is left in doubt about the exact scope and limitation of a few of the counting methods. The addition of more numerical examples, here and elsewhere, would add greatly to the value of the book.

The authors describe the gross effect of the radiations, the production of ionization and the physical and chemical consequences. Dose units and dose rates from various sources, ionization chambers, electrometers, and calorimeters are discussed. The chemical aspects are dealt with very briefly.

The treatment of the applications of radioactivity lays stress on the principles and validity of the methods. The radioactive isotopes and their compounds can be used as markers, tracers and sources of radiation, and illustrative examples are widely chosen from physics, chemistry, biology, medicine and industry: sound advice is offered on the design of experiments. The book finishes with a description of manipulation techniques and hazards, and a useful table of many radioactive isotopes.

The index would be improved by including some of the more common isotopes. Throughout the book, graphs and formulae have been presented in useful forms, and many references are made to original papers, reviews and books: readers who wish to translate the written word into action will find valuable information in this book, though those who are not physicists might appreciate more information on the characteristics of the ideal electronic equipment to be used in conjunction with radioactive isotopes. This would enable an experimenter to assess the power packs, amplifiers, scalars and other equipment available commercially.

In spite of these minor criticisms, the book can be thoroughly recommended. S. J. THOMSON

DISCHARGES IN GASES

Electrical Breakdown of Gases

By J. M. Meek and J. D. Craggs. (International Series of Monographs on Physics.) Pp. ix + 607. (Oxford: At the Clarendon Press; London: Oxford University Press, 1953.) 60s. net.

SIR JOHN TOWNSEND advanced his theory of ionization by collision in 1900 and his theory of the unstable discharge in 1903 (in *The Electrician*). The brilliant researches he afterwards conducted and described in his 1915 book "Electricity in Gases" gave most readers the impression that the fundamental theory of discharges was known and that it remained but to apply it. After 1920 this optimism disappeared mainly because the principles of the interactions between electrons, ions, molecules, radiation and solid surfaces were incompletely known and because the range of possible conditions permits a remarkable proliferation of phenomena. The great

volume of research undertaken since then provided a vast quantity of observed data, greatly improved experimental methods and valuable deductions within limited fields, but the general theory did not greatly advance. Since the Second World War, it has come to be appreciated that Townsend had the roots of the matter and that, with the aid of contemporary advances in physics, workers on discharges can begin to see the complete tree.

Prof. Meek has for long been one of the foremost contributors to the subject, at first with Dr. T. E. Allibone, then with Prof. L. B. Loeb and now with the school he founded himself at Liverpool, in which Dr. Craggs plays a leading part. The authors of "Electrical Breakdown of Gases" are thus essentially qualified for their task of summarizing knowledge of unstable conduction in gases. Their book is as complete as its five hundred pages and profuse, and often beautiful, illustrations allow. It is highly compressed and its twelve chapters have impressive bibliographies. One can only hint at its scope. The first five chapters give the principles of ionic motion, the mechanisms of ionization and recombination, and the concept of the two Townsend ionization coefficients which together can multiply the ionization into an avalanche and can make the discharge self-maintaining. In the light of these principles the behaviour is discussed of discharges at low pressures, then the corona and the spark at higher pressures, where they are distinct phenomena, and finally the lightning discharge, which is the leading example of the long spark caused by a transient voltage. Chapter 6 essays a quantitative theory of the spark based mainly on the streamer and radial-field hypothesis. Chapter 7 deals with the numerical sparkover voltages in cases of practical importance, including the uniform field, the sphere gap and concentric cylinders. Chapters 8, 9 and 11 cover studies ancillary to or somewhat removed from the main analysis, namely, the influence of ionizing radiations, discharges at high frequency and electrode effects. Chapter 10 considers the detailed structure of the actual spark channel as obtained by recent experimental techniques and relates it to theory. The final chapter deals with the important problem of the transitions from the high-resistance glow to the low-resistance arc condition, which may occur in time or in space. Throughout the book reference is made to important engineering and scientific applications at points where the principle discussed is that which determines the application.

The appendix on recent developments might be thought to support a criticism that the authors should have waited to see whether current work is ultimately successful in simplifying some explanations, for example, the direct application of Townsend's equations by Prof. Llewellyn Jones. On the other hand, any later simplification would be offset by the discovery of new phenomena and a valuable and necessary book would stay unwritten. Similarly, though some may think the authors take rather an individual point of view on controversial issues, such as the streamer theory, yet they refer to those who disagree with them, so that the reader can examine the literature and decide for himself. If books are to be written by those who are building up the subjects they treat, then such books must necessarily reflect the original research of their authors. Prof. Meek and Dr. Craggs have written a book which every physicist or engineer interested in gaseous discharges should not merely read but should always consult. S. WHITEHEAD

NUCLEAR REACTOR THEORY

The Elements of Nuclear Reactor Theory

By Samuel Glasstone and Milton C. Edlund. Pp. vii+410. (London: Macmillan and Co., Ltd., n.d.) 35s. net.

SOME of the results of the research and development which were necessary in order to produce the atomic bomb have gradually been made available in scientific journals and in the well-organized volumes of the National Nuclear Energy Series. Hitherto, however, no comprehensive account has been given of the theoretical work underlying the design and operation of nuclear reactors. With the current interest in the utilization of atomic power and the establishment of a nuclear reactor as a valuable fundamental research tool, such a book is long overdue.

Dr. Glasstone and Mr. Edlund have most ably filled the gap with their recent book on nuclear reactor theory. This book is based on a course of lectures which is given at the Oak Ridge National Laboratories for graduates who are commencing work on the reactor research and development programme. As such it is written primarily for physicists and engineers but is of interest to all concerned with reactor design.

For those unfamiliar with the properties of neutrons and their interaction with matter four introductory chapters are provided. These deal with such fundamental concepts as nuclear structures, binding energy, energy-levels, cross-sections and radioactivity, culminating in a discussion of the fission process and a chain reaction. The book is restricted, on security grounds, to a discussion of 'thermal' reactors, which are reactors in which the majority of fissions are caused by neutrons the average kinetic energy of which is approximately equal to that of the atoms and molecules in the containing medium.

This introduction is followed by a detailed mathematical treatment of the behaviour of neutrons in matter. The slowing down of fast neutrons from fission is developed according to Fermi's continuous loss of energy model and their subsequent behaviour according to diffusion theory. The application of this work to the design and properties of homogeneous and heterogeneous reactors is given in two later chapters. A discussion on reflectors includes an indication of the value of the group diffusion method for describing the slowing down of neutrons. This is also considered in a chapter on the general theory of homogeneous multiplying systems.

It is gratifying to find that the authors have found space for this chapter and also for one dealing with the relation between diffusion theory and the more exact transport theory. Such considerations are essential in order to understand in what circumstances the simple treatment given earlier becomes invalid.

There are also separate chapters devoted to reactor kinetics, reactor control and perturbation theory. The effects of control rods and delayed neutrons are calculated, and brief mention is made of the effects of fission products and variation of reactor temperature. It is a pity that space could not be found for a discussion of the use of perturbation theory in treating the two latter effects, which are of considerable practical importance.

A comprehensive subject-index is provided, and at the end of each chapter there are several problems which are of practical interest. Sufficient declassified data are given for the reader to design reactors for himself and to determine their operating characteristics.

Some scarcity of references is understandable in a book which is produced under security restrictions, but more references to experimental work which has been published might have been made.

This book can, however, be thoroughly recommended to those who are interested in reactors and wish to know more about their design, to those who are joining a reactor project for the first time and as a reference book to those who have managed without one for so long. P. W. MUMFERY

RECENT RESEARCHES IN PHYSICS

Reports on Progress In Physics

Vol. 16 (1953). Executive Editor: A. C. Stickland. Pp. iv+407. (London: The Physical Society, 1953.) 50s. net; to Fellows, 27s 6d. net.

THIS, the sixteenth in the series of now annual reports, differs little in outward form from its predecessor. As in Vol. 15 there are nine articles each dealing with advances in a particular field or branch of physics. The standard is high and the reports contrive to get more and more specialized. No longer can the physicist of average attainment or the specialist in a particular branch hope to gain easily by reading these reports an insight into interesting developments outside his present knowledge. The authors assume that their readers have more than a nodding acquaintance with their subjects, and they do not bother to give an adequate introduction or to explain fully and simply the terminology and methods used. Far too many aspects are covered in the one article, and it is obvious from the large number of references which accompany each report that only a few lines of text can be devoted to the work described in each of the papers referred to. Authors of future reports might be invited to provide more background material and to deal more broadly but critically with the important advances in the fields they choose to survey.

The present interest in solid-state physics is reflected by the comparatively large number of reports, five of the nine, dealing with various aspects of crystal and solid properties. The first, which is also the longest article in the volume, is by G. E. Bacon and K. Lonsdale and is devoted to a review of the application of neutron diffraction methods to the examination of the structure of solids. Now that neutron beams of considerable intensity are available from atomic piles, progress in the study of the interaction of neutrons with matter has been rapid in recent years. The report deals in particular with the way in which neutron diffraction has been used to supplement studies by X-ray diffraction, and with structural investigations involving light elements, distinctions between atoms of closely similar atomic number, and studies of magnetic materials.

The relation between the magnetic, optical, piezoelectric and elastic properties of crystals and their structural characters is discussed in a brief report by W. A. Wooster. This is a difficult subject and the experimental data are still inadequate, particularly in reference to the elastic constants, to justify more than broad generalizations. Dr. Wooster deals adequately with the material available. An admirable summary of work done mainly during the past five years on the Raman effect is given in the next report by A. C. Menzies. It is fitting that an article on this

effect should be included in the present volume because the twenty-fifth anniversary of the discovery of the effect by Sir C. V. Raman, who originally used sunlight and complementary filters, occurred last year. Appended to the report is an excellent bibliography which is self-explanatory and largely supplements the text of the article. An attempt is made to provide those not closely engaged in Raman work with a summary of early investigations and with definitions of the technical terms used. A brief statement of what the Raman effect is would perhaps also have been useful.

A report of considerable value, probably the first comprehensive report on the subject, is contributed by B. Bleaney and K. W. H. Stevens, of the Clarendon Laboratory, Oxford. It deals with paramagnetic resonance or the electronic magnetic resonance of loosely coupled systems. The experimental techniques and theory are explained, and mainly only those particular aspects of paramagnetic resonance which are well understood are discussed. A close study of the subject and allied topics has been made by the Oxford group of workers under the supervision of Dr. Bleaney, and the authors of the report give an impartial and authoritative description of what has so far been achieved. However, the mathematical relationships look extremely formidable and it is also difficult for the reader to appreciate what is the real importance and significance of the mass of data, both experimental and theoretical, that is being accumulated.

The final article in the group on solid-state physics is entitled "Semiconductor Circuit Elements" and is written by J. S. Blakemore, of Standard Telecommunications Laboratories, Ltd., and A. E. De Barr and J. B. Gunn, of Elliott Brothers (London), Ltd., Research Laboratories. In spite of its title only a small portion of the report is devoted to the technological applications of semiconductors in the form of diodes, photocells and counters, transistors and other circuit elements. The remainder consists of an excellent, concise treatment, using statistics and band theory, of the electron physics of metals, semiconductors and rectification at metal-semiconductor contacts and *p-n* junctions, followed by an informative discussion of the bulk properties of semiconductors.

Five pages of references accompany the forty-three page article on electrical discharges by F. Llewellyn Jones. Recent developments are surveyed under the main headings of the electrical breakdown of gases in static fields; high-frequency discharges; cold electron emission in discharges; and the régime of space charges. This report supplements several previous reports on the subject. The existence of spontaneous fluctuations sets a limit to the accuracy which can be obtained in the measurement of a physical quantity in a prescribed way, and a valuable account of the ways in which fluctuation theory has been applied to some of the simpler systems—suspended systems, electrical circuits, radiation detectors and feedback—of physical measurement is given in the report by C. W. McCombie. All experimental physicists should study this article, though they may find the theoretical details somewhat difficult to follow.

The remaining two reports in Vol. 16 differ from the rest. They are perhaps the best and the most appealing, one—on cosmology, by W. H. McCrea—because the author makes no pretence at writing a review of recent work, and the other—the new unstable

cosmic-ray particles by G. D. Rochester and C. O. Butler—because it deals with a new field of particle physics which will engage the attention of physicists for many years to come. In the former the main purpose is to describe the lines of thought and to discuss the aims and methods of cosmological theory and not to give a detailed comparison of theoretical and experimental results. The main current theories of cosmology and the model universes yielded by them are reviewed and critically examined, and the general physical features of the actual universe that may be inferred from its comparison with the various theoretical models are discussed. In the latter a detailed description is given of the properties of particles with masses between 400 and 2,200 electron masses. The authors were the discoverers of the neutral V-particles, and the evidence for these and related particles as shown in Wilson cloud chamber photographs of cosmic-ray showers is amply illustrated in a series of beautiful illustrations.

Volume 16 is excellently produced; but there is no index. The reports were again under the general supervision of the Papers Committee of the Physical Society under the chairmanship of Prof. S. Devons, and the executive editor of the publication is Dr. A. C. Stickland, the secretary-editor of the Society.

S. WHINTROUB

THE OXIDATION OF METALS

Oxidation of Metals and Alloys

By Dr. O. Kubaschewski and B. E. Hopkins. Pp. xv+239. (London: Butterworths Scientific Publications, Ltd.; New York: Academic Press, Inc., 1953.) 35s. net.

DURING the past fifteen or twenty years there has been a remarkable improvement in the capacity of metals and alloys to withstand high temperatures under service conditions. The jet engine and the gas turbine have been made possible by the skill of the metallurgist in providing alloys with improved resistance to both creep and oxidation. Generally, more prominence has been given to the improvements in mechanical properties, for these have been the more difficult to achieve and have been made only as the result of great and sustained effort, involving considerable man-power and expensive and impressive creep laboratories. Yet no improvement in mechanical properties would have been of value if it had not been accompanied by adequate resistance to oxidation. The oxidation of metals is therefore a very vital and topical subject for the technologist no less than for the fundamental scientist, who still finds tantalizing problems to be solved in this field. In making a critical survey of the work that has been done on the oxidation of metals the authors have undertaken a task that badly needed doing. The preface states that they have written from the point of view of the individual who is midway between the technologist and the theoretical scientist, but anyone interested in oxidation, from whatever angle, should find this book valuable.

The first chapter reviews the basic information on oxidation and includes useful tables of thermodynamic data, which may be used in deciding which oxide is likely to be formed on an alloy. It is stressed, early on, that most metals and alloys are unstable in air even at room temperature and that therefore the main interest is in the kinetics of oxidation—how rapidly is the oxide formed and what law is obeyed.

As an introduction to the later treatment of mechanism, this chapter includes brief but useful discussions of diffusion and electrical conductivity, and reviews the structures observed in films and scales as well as the effects of gas pressure and temperature on oxidation.

Many experimental methods have been used for the examination and measurement of oxidation; their advantages and limitations are here discussed and illustrated by typical applications. Descriptions of the techniques are brief and the reader is referred to other sources for operational details.

The parabolic oxidation-time law resulting from a diffusion-controlled process is obeyed by many metals within certain limits of temperature when the oxide film has become relatively thick. Accordingly, the authors give a fairly detailed exposition of Wagner's theory of parabolic oxidation and conclude that, within its limits, it may be of great help in the development of oxidation-resistant alloys.

Since it was intended that the emphasis of the monograph should be on fundamental principles and theories of oxidation rather than on oxidation-resistant alloys, it is appropriate that the experimental results should be reported in the final chapter in a somewhat condensed form. In spite of this, the treatment is comprehensive and co-ordinated and the reader will quickly find which original papers are of interest to him. Nearly 550 references are given and there are 84 figures.

Altogether this monograph makes a useful addition to the literature on the subject, and can be thoroughly recommended.

A. G. QUARRELL

ELECTRONS IN METALS

The Theory of Metals

By A. H. Wilson. Second edition. Pp. viii+346. (Cambridge: At the University Press, 1953.) 45s. net.

MANY of the basic principles of the electron theory of metals had been established in the early days of the development of quantum mechanics. By the time the first edition of this well-known book was published in 1936 it was possible to give a theoretical interpretation of many of the salient features of metallic behaviour. The developments since that time, making the appearance of a new edition especially welcome, have been fourfold. First, the mathematical theory has been further advanced. This advance has on the whole been beset with many difficulties and has been slow. Many outstanding problems remain only partially solved, particularly those connected with inter-electronic and electron-lattice interactions having applicability to such physical properties of metals as ferromagnetism and superconductivity. Secondly, there has been a marked improvement in the methods and techniques of numerical calculation. Thus, more accurate values of electronic energies have been obtained by the approximation methods described in the book, and, again, the fundamental transport equation governing conductivity phenomena has been solved with greater accuracy and reliability. Thirdly, it has been realized to an even greater extent that the theory is often so intricate that significant advances may only be possible if increased attention is paid to the analysis of the results of high-accuracy experiments, such results being now forthcoming in growing, though not yet sufficient, numbers. Finally, there has been a growing realization that the theory of

metals, far from being a purely academic field of study, has many applications in technology. An understanding of the theory of semiconductors, for example, to which the author has made such distinguished contributions, has led to the development of the transistor.

Solid-state physics is now a popular field of research, second in volume of significant output perhaps only to nuclear physics. An authoritative account of many aspects of this field, such as is provided in this book, will have a wide appeal. The fact that the theory of metals has come to cover such a wide range of diverse topics has made the inclusion in this book of only selected aspects almost inevitable. By far the greatest weight is given to the theory of conduction. The historical introduction deals with the development up to the Sommerfeld theory, and the formal theory of conduction, deducing the consequences of assuming the existence of a time of relaxation, is discussed in a later chapter. Here a theoretical discussion of one or other of the various 'effects' is usually followed by a survey of experimental data. The theory at this stage is formal, and the following chapter aims at removing this blemish by a detailed examination of the mechanism of conductivity and the physical significance of the time of relaxation. The mathematics is difficult, which is scarcely surprising, considering the complexity of the interaction of electrons with lattice vibrations and impurity atoms. The results of the analysis are not always in agreement with experiment, sometimes not even qualitatively so. Such discrepancies, as in the theory of thermal conduction, do not generally mean that the theory is 'wrong'. The physical situation being so involved, they are more likely to be the result of one or other of the simplifying approximations which make a development of the theory possible at all. Indeed, advances in this field are often consequent only on a re-examination of the validity of such approximations following the discovery that theory and experiment disagree. Other chapters on conduction phenomena include one on semiconductors and a final chapter on the application of the variation principle to the solution of the transport equation, a recent and fertile development in the theory.

Other topics in metal theory are discussed more briefly; nevertheless a surprising amount of detail not generally found in other books is included. Few accounts deal as adequately with the properties of the differential equation governing the motion of electrons in perfect crystals. An important chapter discusses adequately, though in only some forty pages, the various metallic structures as well as their Brillouin zone geometry, and also gives an account of the results of various energy band calculations, of the problems of metallic cohesion and of X-ray spectra in metals. Other chapters discuss the thermal and magnetic properties of metals, including an extensive account of the difficult theory of diamagnetism. A separate chapter treats ferromagnetism from the point of view of the collective electron theory.

In view of the general excellence of this book it is perhaps ungracious to voice one general, even intangible, criticism. The book appears to have too much of the appearance of a treatise on the subject, much as a standard work on some classical branch of mathematical physics. The very fact that there is still great scope for improvement in the theory, especially of its quantum mechanical aspects, is somehow veiled by the inclusion of so many detailed

mathematical deductions from premises based on some theoretical model used, perforce, in the absence of a sounder quantum mechanical description. The elegance of the mathematics should not give the reader a false sense of security, nor blind him as to the possible inadequacies of a particular model in giving an accurate description of what may be a very complex physical situation, of which no mathematical description in closed form may, in fact, be strictly possible.

E. P. WOHLFARTH

METALLURGY AND ATOMIC THEORY

Atomic Theory for Students of Metallurgy

By William Hume-Rothery. (Monographs and Report Series, No. 3.) Second (revised) edition. Pp. 331. (London: Institute of Metals, 1952.) 21s.

THE first edition of this book was published in 1946; it has since been reprinted twice, and now we welcome the appearance of a second edition in which several chapters have been amplified and brought up to date. It is an indication of the steady advance of the subject that a book of this kind, written primarily for honours degree students, should require such additions after so short a period; and the book itself is an indication of Dr. Hume-Rothery's determination to keep students of metallurgy abreast of developments in the fundamental aspects of their subject.

The recasting of this book has increased its size by forty-five pages, and meticulous care has been taken to present the latest data on each subject. For example, the old phase diagram of the copper-gallium system, used primarily for the purpose of illustrating general principles, has been replaced by a later and presumably more accurate one. Again, in the general introduction of Chapter 1 and in the well-known table of electronic configurations, we now find data referring to the transuranic elements. Some of the most interesting of the new material which this edition contains is to be found in Chapter 27 and concerns the behaviour of what are called defect structures. These are alloys in which the electron concentration appropriate to the phase is maintained, during changes of composition, by the creation of vacant lattice sites.

Chapter 29 deals with the difficult problem of the transition elements, and has been considerably extended in the second edition. This is, perhaps, unfortunate. In the introduction to the first edition we are told that "it has been thought better to concentrate mainly on the properties for which the theories have provided a reasonably straightforward explanation, and to avoid those whose interpretation is still in doubt". However, in this chapter, and to some extent in the succeeding one, we find theories which, to put it mildly, have not received general acceptance and which, in truth, are based on vague and unsatisfactory concepts. It is, however, a great merit of this book that none of the theories presented is expressed dogmatically, and little harm should result to the intelligent student if, in fact, some of the hypotheses prove to be wide of the mark. Moreover, there can be no doubt whatever that great benefit will be derived by all who study this excellent book as a whole, and who appreciate its true purpose.

H. JONES

KINEMATICS OF MECHANISMS

Kinematics of Mechanisms

By Dr. N. Rosenauer and Dr. A. H. Willis. Pp. 395. (Sydney: Associated General Publications Pty., Ltd., 1953.) £(A)4 10s.

PROF. ROSENAUER, who lectured on mechanism for many years in the University of Latvia, is now on the staff of the New South Wales University of Technology. The many contributions he has made in this field have been published in various learned journals of Continental Europe, where he enjoys a considerable reputation. This book is based upon his lectures and incorporates the fruits of much of his own research. It is a remarkable book in that it is the first publication on this topic which has appeared in the English language for a great many years. It is to be regretted, however, that the authors did not bear this fact in mind when writing it, for the British or American reader lacks the background possessed by his Continental counterpart, where the subject of kinematics has long been intensively studied. The approach adopted in Britain, in so far as the subject is treated at universities at all, is basically different: we do not lay much store by the extraordinarily thorough enumeration and examination of particular cases, so typical of German texts, to which this book is no exception. It is a large book and consequently costly; one feels convinced that if the material had been condensed to about one-third of its present bulk, and the price correspondingly reduced, the book would have gained not only in attractiveness but also in clarity, for fundamental methods and principles might thus have emerged from their present concealment.

One appreciates that it is a relatively novel departure for an Australian publisher to produce a scientific work of this magnitude, and since it is such a laudable venture one hesitates to criticize the production, which leaves something to be desired by British standards: the paper is not really suitable for printing fine line-blocks, of which there are nearly four hundred, and no attention has been paid to the size of lettering for the diagrams, in the light of their future photographic reduction for block-making. The result is that the letters vary in height on different diagrams between 1/16 in. and 3/16 in.

Although British and American work in this field is scarce enough, it is regrettable that the authors omit mention of even this little. Some of the work on kinematic chains published in Britain in 1950¹ is more general and more elegant than that given in the chapter devoted to this topic. There is no mention of 3-dimensional- (or space-) mechanisms, though an introduction to this topic would have been valuable, especially as it is in this field that there has been much American and some British activity in recent years.

The somewhat academic Euler-Savary and Bobillier methods, which take up much space, might well be omitted or mentioned merely in passing. On the other hand it is most useful to have, for the first time in book form, an account of Prof. Rosenauer's use of orthogonal velocity vectors on which are based many of the constructions in this book.

The final chapter is entitled "An Introduction to the Synthesis of Mechanisms". To design a mechanism to meet a given specification is, of course, the engineer's whole object in studying the kinematics of mechanisms. One or more points of the mechanisms are required to approximate as closely as possible to

a given motion, both in position and velocity, with limitations on the permitted accelerations of all parts of the linkage. There can be no question but that British mechanical design would benefit considerably if the underlying principles of kinematic syntheses were more clearly enunciated and more widely known. This chapter is a step in the right direction, but a far more fundamental examination and exposition of the properties of the four-bar chain are required to fill the present gap. Such matters as are treated in the chapter on straight-line motion would fall out of such an analysis as important special cases. Until such time as this is attempted, the designer will be content to rely upon atlases of curves, such as those recently produced at the Massachusetts Institute of Technology.

The authors and publishers are to be congratulated on their production of a most valuable book. It is sincerely to be hoped that this pioneering effort will inspire others to enter the field with works which will be of more direct value to practising engineers and which will make a greater appeal by adopting a fundamentally different approach, more in tune with the British engineer's background.

THE ART AND SCIENCE OF DESIGN

The High-Speed Internal-Combustion Engine

By Sir Harry R. Ricardo. Fourth edition, rewritten and reset. Pp. ix+420. (London and Glasgow: Blackie and Son, Ltd., 1953.) 40s. net.

SOME years ago the reviewer was discussing tank design with one of its leading German exponents, who prefaced his comments on tank engines by remarking that German designers had found their inspiration in the translation of an early edition of the present book, and that he could not understand why so little attention had been paid to Ricardo's work in his own country.

Although this book is called the fourth edition, comparison with the third edition quickly shows that the impression thus given is entirely misleading; both books should be found on the shelves of every engineer, since not only does each contain much that is not to be found in the other, but also, taken together, they offer a fascinating insight into the workings and development of a powerful mind faced with the creative problems of design and manufacture.

Sir Harry Ricardo, in his presidential address¹ to the Institution of Mechanical Engineers, presented an autobiographical sketch of his development as an engineer which held his audience spellbound. Into this, his latest monograph, he has distilled such balanced wisdom on his own special field as every designer would wish to be able to do. Here are to be found the analysis of much research work, carried on over a period of almost fifty years, the experience and the conclusions he has drawn from it, the guesses and the surmises, the rational and the apparently irrational preferences; in short, the whole wealth of mind that is needed for great creative engineering. No engineer who has reflected on the problems facing himself can fail to be stimulated by the unique

presentation; yet at the same time the book is such as should be made compulsory general reading for every engineering undergraduate. It is, indeed, a cause for reflection that Ricardo started on the research work that was to shape his life's work when Bertram Hopkinson suggested to him that he should stop reading for the Mechanical Sciences Tripos at the end of his first year in order to assist in Hopkinson's work on knock, and thus left Cambridge labelled only with a pass degree.

While the chapter headings suggest that this is a comprehensive work on the high-speed internal combustion engine, its weakness as its strength is that it makes no pretence at being other than a monograph. There are neither footnotes nor references, nor is there more than occasional remark on the sources on which the author has drawn beyond his own laboratories; thus the reader unacquainted with the field might be led to accept as gospel certain matters which are open to dispute, and in matters where he might like to study more deeply, no clue is available as to where he should turn for more detailed information. This, however, is carping criticism, since an engineer whose writings display the full apparatus of scholarship is scarcely likely to have found time for the hard and laborious work involved in great mechanical design. D. B. WELBOURN

LOGIC FOR MATHEMATICIANS

Logic for Mathematicians

By Prof. J. Barkley Rosser. (International Series in Pure and Applied Mathematics.) Pp. xiv+530. (London: McGraw-Hill Publishing Co., 1953.) 85s.

THERE are many expert mathematicians who know little or nothing of symbolic logic. They have, of course, heard of Whitehead and Russell's "Principia Mathematica"; but cannot spare the time from their own researches to master its formidable difficulties. Now they have the chance to become acquainted with the subject much more easily. Prof. Rosser, by using Quine's technique, invented since the writing of "Principia Mathematica", claims to have condensed most of its three large volumes with its "out of date and extremely unwieldy symbolic machinery" into one book of moderate size.

The first chapter is addressed to those mathematicians who are not only completely ignorant of symbolic logic, but are also sceptical of its importance. This and the next four chapters seek to convert the unbeliever and to lead him very gently into the true faith, encouraging him by frequent references to the application of logical principles to ordinary mathematical theorems. But the reader who expects a mere confirmation of what he has always known will experience many shocks. "Some of these basic logical principles used by all (or almost all) mathematicians may actually not be valid. . . . Actually, some . . . have been subjected to severe criticism, notably certain uses of *reductio ad absurdum*". Moreover, "there is equally no guarantee that the symbolic logic is itself valid". However, from these principles—none known to be invalid, though some under suspicion—can be derived the existing body of mathematics, which is certainly useful in science and engineering.

The remaining ten chapters are more difficult reading; but even those who care little about logical technique will be interested by many references to ordinary mathematics. It is comforting, in these days of widespread references to electronic 'brains', to read that Alonzo Church's theorem proves that no machine can ever solve all problems solvable by a live mathematician. But mathematicians will not be pleased to be convicted of using the word function in two different senses, and thus producing confusion in a well-known treatise on the theory of functions. Much more disconcerting are the references to Gödel, Cantor, and the axiom of choice. According to a theorem of Gödel, "if a system of logic is adequate for even a reasonable facsimile of present-day mathematics, then there can be no adequate assurance that it is free of contradiction. . . . In fact, there is the awkward possibility that present-day mathematics is actually in serious error. . . ." "Cantor's theorem, to the effect that no class is similar to the class of all its sub-classes . . . is very useful in the classical theory of cardinal numbers. Unfortunately it seems to be false." But Prof. Rosser offers another theorem, which he believes to be true, to replace it.

There is a full discussion of the axiom of choice. Many mathematicians absolutely reject it. Some accept it readily, others with reluctance, doing so only because they believe that many valuable branches of mathematics are founded on it. Some who cannot accept the axiom in its usual form consider a weaker form, "the denumerable axiom of choice", far less objectionable, and on this a considerable amount of useful mathematics can be founded. ". . . to the best of our knowledge, one cannot prove the first fundamental theorem of Lebesgue without an appeal to the denumerable axiom of choice." "In topology, the axiom of choice is assumed from the very start. . . . Moreover, the question of how much topology could be done without the axiom of choice is apparently receiving no attention at all."

The last chapter sums up the principles established in this valuable and interesting book and applies them to an analysis of the merits and faults of some of the most esteemed mathematical treatises. It concludes with a bibliography and index. Nearly every chapter contains examples for solution. Every pure mathematician should read this book; unfortunately the very high price will mean that many will have to borrow it from a library, instead of buying a copy for themselves. H. T. H. PRAGGO

NUMERICAL ANALYSIS

Numerical Analysis

By Prof. D. R. Hartree. Pp. xiv+288. (Oxford: Clarendon Press; London: Oxford University Press, 1952.) 30s. net.

PROF. HARTREE'S book makes a considerable step forward in the literature of numerical analysis. The subject has a long history. It arose originally from the needs of navigators and astronomers and in the earlier days consisted largely of trigonometrical and geometrical applications. Later, calculations were aided by the invention and use of logarithms. Then elementary statistics was added, so that by the time the standard text-book of E. T. Whittaker and G. Robinson came to be written, an appropriate title appeared to be "The Calculus of

Observations", in spite of the fact that a large proportion of the book deals with finite differences and other tools of the makers and users of mathematical tables.

The Second World War greatly increased the demand for numerical work and stimulated the study of methods. In fact, numerical analysis is now recognized as a 'respectable' subject for mathematical study. Thus, although "The Calculus of Observations" has been a standard text-book for several decades, and remains a scholarly and useful book, it was written in the early days when computing was done with logarithms or with the earliest barrel-type hand machines. It is consequently lacking in numerical illustrations and examples adequate to present-day needs.

Other interesting and valuable books have also appeared from time to time, but they have either been too elementary to cover the most successful methods and formulae of modern numerical analysis, or they have been advanced and specialized mathematical text-books on the theory of finite differences and difference equations.

A further line of recent progress has been the rapid development of automatic electronic computers, with fantastic speeds of performance of elementary numerical operations. With their development, there has grown up a considerable body of users who have not had prior training in computing with desk machines, and who are unfamiliar with the many useful techniques that have been developed. There is thus a tendency to use simple, repetitive or iterative, but above all obvious, methods of computation on electronic machines and to argue that such methods are appropriate for such machines.

There is, then, a clear need for a book for practical computers, whether working with desk or automatic machines, which will show them the kind of process which may or should be tackled numerically, which will tell them the best processes to use for carrying out the numerical work, and which will provide examples, both worked and unworked, to help them to attain a better understanding of the processes described.

Prof. Hartree's book meets all these needs. The aim of the book is practical, so that no attempt is made to cover ground beyond practical needs, interesting though much of this may be. For each process, the formula or method advocated as best is given in detail. Some further good methods are also described in case the author's choice should not quite meet the user's needs. Very considerable emphasis is placed on the importance of *checking* and on methods for doing this.

The derivation and use of finite difference formulae is covered thoroughly, with almost exclusive emphasis on the use of *central* differences, followed by chapters on interpolation, integration and differentiation, and on the integration of ordinary and partial differential equations. Linear and non-linear algebraic equations, and matrices are covered fully, while a brief account is given of methods for summation of series, harmonic analysis, and smoothing (with adequate cautions on the often unappreciated dangers of this process).

A final chapter on the organization of calculations for an automatic machine gives an indication of possibilities that will be more and more widespread in the future.

This is a book that can be recommended for all computers of all ages—experienced or otherwise—and particularly as a text-book for students.

J. C. P. MILLER

SHORT REVIEWS

Whipsnade

By Philip Street. Pp. 128+31 plates. (London: University of London Press, 1953.) 12s. 6d. net.

THIS is really a dual-purpose book: it describes the birth and development of Whipsnade Park and is an 'everyman's' natural history of the inmates. In addition, it takes everyman behind the zoological scenes to make him understand the magnitude of the task of maintaining the Whipsnade estate and keeping the animals happy and healthy.

The history of Whipsnade makes most interesting reading and demonstrates the courage, energy and imagination of Sir Peter Chalmers Mitchell and Dr. Geoffrey Vevers.

It is depressing to read of the number of species which are either extinct or nearly extinct through the depredations of sportsmen and the demands of agriculture. There is a dramatic story of the rescue of the Père David deer by the tenth Duke of Bedford, who built up a flourishing herd from the eighteen known survivors of the species of which the thriving Whipsnade herd is an offshoot.

The natural-history section, well written and clear, leaves the reader speculating and anxious for further information; but as it is written for the layman it is rather misleading to say that most of the mammals in Australia are marsupials; except for some bats and the odd mouse the indigenous mammals of Australia were marsupials; but since man arrived placental mammals are gradually ousting the native fauna. The statement, too, that deer do not exist in Australasia is only partly true in that they have been introduced by man in recent times and the red deer is flourishing in New Zealand.

The omission of a chapter on the anthropoids seems a pity; but these are small blemishes on a book which tells of an exciting experiment, in language which is plain, undramatic and elegant and which should do much to send its readers to Whipsnade to see for themselves.

Journal of Researches into the Geology and Natural History of the Various Countries visited by H.M.S. Beagle

By Charles Darwin (1839). Facsimile reprint of the first edition. (Pallas, a Collection of Offset Reprints of Out-of-print and Classic Scientific Works, Vol. 2.) Pp. xiv+615+16 plates. (New York and London: Hafner Publishing Co., 1952.) 55s.

IT is now 127 years since a young geologist, aged twenty-seven, returned to England from a five-year voyage. At an age when most men are starting upon their careers, young Darwin had seen memorable service as naturalist in H.M.S. *Beagle*: his mind was full of information that was to be sifted, interpreted and re-interpreted until it became the basis of the "Origin of Species" more than twenty years later.

Despite all that is said to-day about Darwin and Darwinism there must be many who have not read the classic "Journal" in which the day-to-day discoveries were noted, and on every page of which the imprint of new experience is clearly recorded. One can still read the story for its intrinsic interest, with admiration for the tenacity, the physical toughness and the insatiable curiosity of the traveller.

Certainly the pleasure of reading is enhanced in this fine facsimile of the 1839 edition, which is clearly printed and has the original notes, illustrations and index. Some illustrations have been added from the earlier narratives of Captains King and FitzRoy, and the diagrammatic drawing of the *Beagle*, made many years later by Captain King, has also been included.

The closing words of the volume recommend travel as teaching "good humoured patience, freedom from selfishness, the habit of acting for himself, and of making the best of everything, or in other words contentment". Darwin also says "To hoist the British flag, seems to draw with it as certain consequences, wealth, prosperity and civilization". To these extracts one can only add: *O tempora. O mores.*

W. E. SWINTON

A Field Guide to the Birds of Britain and Europe

By Dr. Roger Peterson, Guy Mountfort and P. A. D. Hollom. Pp. xxxiv+318+64 plates. (London: William Collins, Sons and Co., Ltd., 1954.) 25s. net.

A GOOD handbook on European birds for use in the field has long been wanted. It is true that some thirty years ago Wardlaw Ramsay wrote a handbook on European and North African birds, but it had no coloured plates and the descriptions were more of birds in the hand than in the field.

In the present volume every bird is figured either in colour or black-and-white and, in addition, there are lines on the plates pointing to the principal different markings of any two birds which appear similar in life. Opposite the plates the chief characters of each species are clearly given, and as birds of prey are, as often as not, seen on the wing—they are shown in flight.

The introduction has valuable illustrated notes on how to identify birds, and where and when they are found, with a timely note of caution as regards rarities. The letterpress is short—a few lines on size and markings, a line or two on voice, and finally a short note on habitat and nests. At the foot of many of the pages are useful distribution maps.

The authors are to be congratulated on producing a veritable *multum in parvo* on European birds.

N. B. KINNEAR

Logic and Psychology

By Jean Piaget. Pp. xix+48. (Manchester: At the University Press, 1953.) 6s.

THIS small book is based on three lectures given in the University of Manchester in 1952. The brief historical survey in the opening chapter explains why there is little co-operation at the present time between logicians and psychologists. The second chapter deals with the four main stages, extending over the period from birth to maturity, in the psychological development of operations. Finally, the operational techniques of modern logic are used for discovering and constructing structures which can be put into correspondence with the operational structures of psychology, and the use of these logical structures in psychological interpretation is discussed.

The symbolic algebra used in the third chapter is more readily understood by the short survey, written by one of the translators, of the more important

concepts of the algebra of logic which Piaget has applied to the analysis of the intellectual activities of the child.

The book makes a further contribution to the study of the application of logical techniques to psychological facts, and especially to the thought structures found at different levels of intellectual development.

Man and Number

By Donald Smeltzer. Pp. viii+114. (London: Adam and Charles Black, Ltd., 1953.) 7s. 6d.

THE book gives an interesting account of the development of man's use of number and of the social and practical influences which have affected that development; it shows how early man acquired a sense of number and the gesture and spoken languages of number; it traces the evolution of the written language of number with early methods of recording numerical information and carrying out calculations to the wonderful inventions of modern calculation—the Arabic notation, decimal fractions and logarithms. The final pages of the book deal with inconsistencies and disadvantages in our present number system and how they might have been avoided by scientific planning. There is a useful bibliography but no index.

The appearance of such a book is a welcome addition to the small number of books on the history of mathematics of appeal to the general reader who is interested in human customs and their evolution, and to pupils in secondary schools. To the teacher of elementary mathematics the book will serve as an introduction to the more detailed works of Smith, Cajori and Rouse Ball, and as a source of material for inclusion in classroom lessons.

Earth Science

By Gustav L. Fletcher and Caleb Wroe Wolfe. Third edition. Pp. viii+556. (Boston, Mass.: D. C. Heath and Company; London: George G. Harrap and Co., Ltd., 1953.) 21s.

THIS book is primarily designed for teaching the background of physical geography and geology to students of, possibly, rather unequal attainments. Each chapter is conveniently paragraphed on the decimal system and followed by exercises. It is adequately illustrated by diagrams and photographs; examples are nearly all taken from the North American continent. The style of writing is simple and direct, with suitable typography; so from the students' point of view it is easy to read. Of the thirty-four chapters, twenty-one are devoted to geological subjects, four to astronomy, and seven to the atmosphere. These are followed by appendixes, a bibliography, and index.

Students of physical geology and geography must be presumed to have had a grounding in simple physics and chemistry; but the book includes some irrelevant, trivial and very elementary matter which makes it of uneven quality, and it contains several statements which are inaccurate or insufficient: for example, the assurance (p. 396) that "you are not likely to be struck by lightning if standing under a tree".

The list of books recommended for reading with each subject could well be extended, but deserves careful grading from elementary to highly advanced. The authorities cited are mainly American with a sprinkling of British, and there are some notable omissions from both sides. Much of the geological

material and principles was anticipated in that little old classic, W. W. Watts's "Geology for Beginners", which surely ought not to have escaped the notice of the authors.

"Earth Science" is a compendium of useful information presented in a form easy to assimilate and to memorize; but it attempts both the formality of a text-book and the naïveté of a children's encyclopedia, and merits a careful pruning.

D. W. BISHOPP

The Oxidation States of the Elements and their Potentials in Aqueous Solutions

By Prof. Wendell M. Latimer. (Prentice-Hall Chemistry Series.) Second edition. Pp. xvii+392. (New York: Prentice-Hall, Inc.; London: Constable and Co., Ltd., 1952.) 42s. net.

THE first edition was published in 1938 and had 352 pages. In it the author not only assembled the scattered mass of free-energy data, but he also expounded methods of combining these data for the determination of the thermodynamic properties of ions in solution and for the interpretation generally of chemical behaviour. The value of his work as a thorough survey of this important field was soon recognized. Prof. Latimer has now extended his tabulation so that for each element the heats of formation, free energies of formation and entropies have been given for all important compounds. Also, he has added potential diagrams for all elements having more than one oxidation state; he has treated reaction mechanism more deeply; and has inserted the chemistry of the actinide elements.

Of the four old appendixes, 2 and 3, summarizing free energies of formation and equilibrium constants respectively, have been incorporated in the text. A new appendix (3) discusses methods of making accurate estimations of entropy values; finally, a new appendix (4) contains a set of questions and problems for study. The book has already established itself as a standard work and the extension and revision have enhanced its usefulness.

G. FOWLES

Small-scale Inorganic Qualitative Analysis

By Dr. J. T. Stock and P. Heath. Pp. iv+96. (London: University Tutorial Press, Ltd., 1953.) 4s. 6d.

WRITTEN by experienced teachers and entirely devoted to practical work, this is a complete book of small-scale analysis for students taking examinations of the British first-year university level. The introductory section of four chapters on apparatus, materials and techniques is extraordinarily well done. The descriptions of essential pieces of apparatus, such as the test-pipette, the centrifuge, the micro-slide and the special hydrogen sulphide reservoir, are given with a clearness and directness that could come only from a first-hand knowledge of small-scale analysis and long experience of its teaching. Where circumstances may not permit of the acquisition of the recommended pattern of apparatus the authors often describe simple home-made substitutes. Chapters 5-18 describe a scheme for the analysis of simple mixtures of customary acidic and basic radicals using the detailed small-scale procedure. In the scheme the authors employ the excellent zirconium method for the removal of phosphate, make sparing use of organic compounds, and generally adhere to well-tried methods of separation and identification. A summary of the scheme

appears later in the book in the form of a series of tables. Semi-micro analysis has come to stay and older teachers, unacquainted with its techniques, could rapidly master this book and give instruction with confidence.

G. FOWLES

Fundamentals of Chemistry

By Prof. L. Jean Bogert. Seventh edition. Pp. xx+648. (Philadelphia and London: W. B. Saunders Company, 1953.) 22s. 6d.

THE "fundamentals" are not only established but are also applied to medicine and the related arts. Of the book's thirty-two chapters nineteen deal with general chemistry and seven with organic compounds. All the chapters have been revised and some entirely rewritten: Chapter 18, on radioactivity and atomic energy, is new to this edition. In simple language and with unusual clarity Prof. Bogert gives a good introductory account of the elements and their chief compounds and of fundamental physical principles. He omits all mention of industrial processes and concentrates on the chemistry concerned with the living cell. Items of the contents illustrate this emphasis: colloids in the living organs, function of proteins in the body, physiological importance of oxidation, etc. The last six chapters deal severally with: the vitamins; digestion and the digestive enzymes; transportation, blood and lymph; metabolism; endocrine glands and their hormones; elimination, urine, and faeces. The versatile author excels in these chapters, for he has the rare ability of correlating his knowledge of chemistry and physiology, of selecting what is important and of expounding its significance. The book should appeal to students of medicine, hygiene and dietetics. In addition the reviewer would recommend it for the nursing school and for domestic science where this is taken at sixth-form level.

G. FOWLES

Estimation of Organic Compounds

By Dr. F. Wild. Pp. viii+239. (Cambridge: At the University Press, 1953.) 25s. net.

THIS little book brings within two covers a collection of the various means of determining organic compounds through the characteristic groupings present; its scope is deliberately limited to general methods, so that the more specialized fields, for example, sugars, sulphonamides and amino-acids, are not considered.

The scheme adopted can be illustrated by the treatment accorded to olefinic linkages. Hydrogenation, both on the macro- and micro-scale, is described in detail, as are also methods for bromine, iodine and thiocyanogen numbers and the allied process using peracids; there are also a number of miscellaneous methods given in brief form. The inclusion of iodine numbers in a book of this kind is interesting, since it is usually necessary to refer to works on applied analysis of more specialized character for descriptions of such methods.

Other classes treated on similar lines are alcohols and phenols, mercaptans, aldehydes and ketones, amines, nitriles, nitro-, acetyl- and benzoyl-compounds and the lower alkyloxy- and alkylimino-compounds. A few others, for example, nitroso compounds and isocyanates, are discussed in less detail. In some of the classes, particular methods for some individual members are included, for example, methanol (but not ethanol), formaldehyde, acetone. The Karl Fischer reagent is introduced under carbonyl compounds.

Experience would soon reveal that the 60 per cent strength quoted (p. 36) for a toluene solution of maleic anhydride is incorrect; the spelling 'xylydene', which occurs more than once, is unusual. These are, however, minor blemishes on a work which, with its companion volume in the qualitative field, will give the organic chemist a sound and useful start.

B. A. ELLIS

A Short Course in Organic Chemistry

By Harold Hart and Robert D. Schuetz. Pp. ix+326. (Boston, Mass.: Houghton Mifflin Company, 1953.) 4.50 dollars.

THE format, for a book of this class, is uncommon; its dimensions in inches, $10\frac{1}{2} \times 6\frac{1}{2} \times \frac{7}{16}$, and its large clear type permit of the bold presentation of important notes. The illustrations are varied and striking; indeed, the line drawings, the many plates in half-tone, the pictures of electron clouds, and the numerous ball-and-peg molecular models, disclose the authors' confidence in visual aid. The course, framed for adult students who need a working knowledge of organic chemistry but whose main interest lies in such fields as those of medicine, dentistry and agriculture, follows no prescribed syllabus. The scope is roughly the requirements in organic chemistry of the British university first-year course, but includes also the simple chemistry of petroleum, plastics, rubber, textiles, dyes, and explosives, as well as of vitamins, hormones and antibiotics. The approach is not by the study of alcohol, or by the analysis of organic compounds—a section entirely omitted—but by the electronic theory and the explanation of simple reaction mechanisms. The judgment shown in the selection and arrangement of the material is to be commended. The main emphasis is on biological aspects and on everyday applications of recent discoveries. The treatment is clear and interesting, yet a topic requiring effort for its understanding, such as optical isomerism, is not avoided. In general, aliphatic and aromatic compounds are treated together. The simple applications of the electronic theory, the use made of the structure of molecules, and the up-to-date information should commend this book to teachers as well as to the class of students for whom it was written.

Notes on Qualitative Analysis

By H. J. H. Fenton. A new edition, by Dr. B. C. Saunders. Pp. vii+126. (Cambridge: At the University Press, 1953.) 15s. net.

THAT many years have passed since this book was revised is a testimony to the worth of Fenton's tables of analysis and to his selection of reagents. Dr. Saunders has put into this edition not only his own experience but also that of his colleagues at Cambridge. He has changed the tables but slightly, adding here and there an alternative separation, and he has inserted a well-chosen selection of modern reagents and procedures. Among these are Holness's effective way of bringing the arsenic group sulphides into solution and both the titanium and the zirconium methods for the removal of phosphate. Apart from this, with the purpose of extending the use of the book to the sixth form of schools, he has made considerable alterations. Gone are the fifty pages on the reactions of organic compounds and in place appears a section on microanalysis. Dr. Saunders has rewritten the notes on theory, he has removed from the analytical tables substances not found in Advanced Level (General Certificate) syllabuses, and

he has added a simple outline plan of the scheme of analysis. The last item is a good teaching aid for it helps a student not to lose his way. The revision has been well done and "Fenton" is now a useful and reliable book for use in schools. G. FOWLES

Five-Membered Heterocyclic Compounds with Nitrogen and Sulfur or Nitrogen, Sulfur and Oxygen (except Thiazole)

By L. L. Bambas. (The Chemistry of Heterocyclic Compounds, a Series of Monographs, Vol. 4.) Pp. xi+403. (New York and London: Interscience Publishers, Inc., 1952.) 14 dollars.

THE principal themes of this volume—the fourth of the present series of monographs—are provided by thiadiazoles and isothiazoles. The latter compounds are known only as condensed ring structures as in the benzisothiazoles, whereas the former comprise both monocyclic and condensed cyclic types. These two groups of azoles, together with their selenium analogues, occupy the whole text except for eight pages devoted to representatives of the little-known dithiazoles, dithiadiazoles, thiatrazoles and oxathiazoles. Rational subdivision of each of the main themes allows individual topics to be treated on historical lines, and the author has not hesitated to introduce a controversial note by adding occasionally his own interpretation or point of view. As in earlier volumes of the series the text is profusely illustrated by admirably clear structural formulae and is supplemented by tables of preparative methods and physical constants for individual compounds: an adequate index is provided. Although current interest in the subject-matter is comparatively slight, the book nevertheless affords an excellent survey of its field and contributes its full share towards the major work of reference of which it forms a part.

J. D. LONDON

L. Farkas Memorial Volume

Editors: Adalbert Farkas and Eugene P. Wigner. (Research Council of Israel: Special Publication No. 1.) Pp. ix+309. (Jerusalem: Universitas Booksellers, 1952.)

THIS volume contains papers by teachers, colleagues, pupils and friends of Ladislav Farkas, who lost his life in an air accident in 1948. A portrait of him and an appreciation by Sir Eric Rideal appear at the beginning of the volume. There are twenty-four papers by authorities on a variety of subjects, all of which are interesting and useful. Some deal with reaction kinetics, including fast reactions, others with catalysis, adsorption, and enzymes. Farkas was professor of physical chemistry in the Hebrew University of Jerusalem, and all those who recognized the high quality of his work and his great promise must regret that his career was so tragically closed. This volume will serve as a reminder of one who was esteemed by all who met him.

J. R. PARTINGTON

Radiation Chemistry

Discussions of the Faraday Society, No. 12. Pp. 319. (Aberdeen: Aberdeen University Press, Ltd., 1952.) 35s. net.

THE well-known excellence of the General Discussions of the Faraday Society makes it unnecessary to do more than direct attention to the fact that one on radiation chemistry is available. The papers are fairly short, but they give intelligible accounts of their subjects and the discussions are helpful in that they introduce new material or new

aspects of the topics with which they are concerned. What is now called radiation chemistry deals mostly with the effects of X- and γ -rays in inducing chemical reactions. Most of the work is concerned with liquids, both organic liquids and aqueous solutions. Since organisms all contain water or solutions, the subject has a biological aspect. In some cases radiation may bring about polymerization, in other cases it may create free radicals. The exact mechanism is still not always fully understood and differences of opinion exist. The Discussion provides a good and intelligible survey of the subject and will be useful to many classes of reader. J. R. PARTINGTON

Physical Chemistry for Colleges

A Course of Instruction based upon the Fundamental Laws of Chemistry. By Prof. E. B. Millard. (International Chemical Series.) Seventh Edition. Pp. ix+618. (London: McGraw-Hill Publishing Co., Ltd., 1953.) 51s.

PROF. E. B. MILLARD'S book is probably well known to most teachers of physical chemistry, and it is only necessary to say that the fact that it has reached a seventh edition since it was first published in 1921 is an indication of its excellence. The text has been largely rewritten and rearranged, new material being added when necessary. Problems on topics usually found difficult by students are included. References to original papers have been carefully selected so that students may be encouraged to read at least some of them; many are to American publications, but by no means all. A good feature of the text is the experimental approach; although actual experimental methods and descriptions of apparatus do not appear very prominently, all the fundamental laws are discussed on the basis of numerical results rather than in an abstract or formal way, and most teachers will agree that this is the best way of making their meaning clear to students. It is very likely that individual teachers will vary the order of presentation somewhat; the reviewer thinks the section on thermodynamics (Chapter 18) could well come much earlier in the book, and the electrochemistry is rather condensed. More space is given to equilibrium and phase rule and to kinetics. There is little doubt that this book will continue to be popular, and the care which the author has taken in the revision will be appreciated.

J. R. PARTINGTON

Starch and Its Derivatives

By J. A. Radley. Vol. 2. Third edition, revised. (Being Volume Twelve of a Series of Monographs on Applied Chemistry, under the Editorship of Dr. E. Howard Tripp.) Pp. xi+465+35 plates. (London: Chapman and Hall, Ltd., 1953.) 65s. net.

THE second volume of Radley's comprehensive treatise on starch and its derivatives deals mainly with industrial aspects, including the manufacture of starch, the production of derivatives and the applications of these materials in adhesives, paper, textiles and foodstuffs. A detailed discussion is given of the methods of analysis available for the assessment of starches and starch products.

The text of many sections is substantially the same as that of the second edition published in 1943, new information being given only in the form of additional references and brief notes. New chapters have been contributed on the manufacture of corn starch (R. W. Kerr), on the production of chemicals from starch by fermentation processes (L. M. Christensen

and L. A. Underkofler), on the role of starch in bread staling (C. W. Bice and W. P. Geddes) and on physical methods for the characterization of starches (C. C. Kesler and W. G. Bechtel). These two volumes bring together in convenient form a mass of carefully documented information concerning the fundamental chemistry and technology of starch and starch derivatives. Like the earlier editions, this one also will be of the greatest value to all concerned with the study or manufacture and use of these materials.

E. L. HIRST

Chemistry of Carbon Compounds

A Modern Comprehensive Treatise. Edited by Dr. E. H. Rodd. Vol. 2, Part A: Alicyclic Compounds. Pp. xciii+488. (Amsterdam and New York: Elsevier Publishing Co. Inc.; London: Cleaver-Hume Press, Ltd., 1953.) 84s.

THIS volume fully maintains the high standard set in Vol. 1 (*Nature*, 170, 508; 1952). It is, however, more uniform in style, being largely the work of one author, Prof. R. A. Raphael, who has produced an excellent account of the chemistry, including the stereochemistry, of the various alicyclic types from single rings to polynuclear, condensed and bridged-ring systems and spiro compounds. Two short sections, on pyrethrins and hydnooarpic acids, are contributed by Dr. L. Crombie. Carotenoids are dealt with fully in a chapter by Dr. R. H. Hunter, and Dr. R. G. R. Bacon contributes a summary of polymeric derivatives of olefinic compounds, mainly rubber and rubber-like compounds, which are included here since the terpenes are included in Vol. 2B.

Like the previous volumes, this provides an authoritative source of accurate, detailed and up-to-date information, and includes numerous references to the original literature and review articles.

C. BUCHANAN

Kinetics and Mechanism

A Study of Homogeneous Chemical Reactions. By Prof. Arthur A. Frost and Prof. Ralph G. Pearson. Pp. vii+343. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 48s. net.

THE authors state that there was need of a book giving an adequate account of the relations between kinetics and reaction mechanism, and they have attempted to fill this gap. There is no doubt that the result is satisfactory. It can serve as a text-book for advanced students, a guide to young lecturers, and a reference book which, since it contains bibliographies, will put the reader in touch with the literature. Although many of the examples are chosen from recent publications, the classical investigations, such as those of Harcourt and Esson, are by no means neglected, and it is clear that the authors have read and digested a wide field of literature, not confined to that published in the United States. There is an intelligible account of the transition-state theory, the rather difficult subject of complex reactions is dealt with systematically, and the recent investigations on the mechanism of organic reactions as elucidated by their kinetics are very well covered. Some parts, such as catalysis and chain reactions, are rather briefly considered, but there are other sources available for these. Since the mathematical parts are clearly set out, a student should not have much difficulty in following the text. This is a book which can be recommended.

J. R. PARTINGTON

Changements de phases

Comptes Rendus de la Deuxième Réunion Annuelle tenue en commun avec la Commission de Thermodynamique de l'Union Internationale de Physique, Paris, 2-7 Juin 1952. Pp. ix+487. (Paris: Société de Chimie Physique, 1952.) 3750 francs.

THIS volume contains no fewer than sixty-five papers on various aspects of its subject, and discussions on them. Some of the communications are short, and one consists of only sixteen lines. The subjects are arranged in eleven groups, namely, condensation, critical phenomena, phase equilibrium in solutions, solutions of polymers and colloids, co-operative phenomena in solids, polymorphism and rotation transitions, kinetics in solids, ferromagnetism and lambda-points, fusion, transitions in amorphous bodies, and transitions in surface phases. The papers are accompanied by short bibliographies. The collection will no doubt be very useful to those working in the field; but the treatment is, in general, too condensed to be easily understood by others, and it might have been better to have dealt with a more restricted field and to have had fewer papers. It would also have been useful to have included summarizing papers for each group, so that the general results of the work could be ascertained. The lack of agreement disclosed in the discussions is also confusing to those not actually working in this field. The discussion was probably of value to the participants; but the general reader may wish for a more homogeneous and critical survey of the important subject than is presented here.

J. R. PARTINGTON

Data for X-Ray Analysis

(Philips' Technical Library.) Vol. 1: Charts for Solution of Bragg's Equation (d versus θ and 2θ). By W. Parrish and B. W. Irwin. Pp. vii+100. Vol. 2: Tables for Computing the Lattice Constant of Cubic Crystals. By W. Parrish, M. G. Ekstein, and B. W. Irwin. Pp. vii+81. (Eindhoven: N.V. Philips Gloeilampenfabrieken; London: Cleaver-Hume Press, Ltd., 1953.) 15s. each.

VOL. 1 contains graphs of lattice spacing against Bragg angle, covering a range from about 85° down to low angles corresponding to spacings of 21 Å., for chromium, iron, cobalt and copper $K\alpha$ radiations; the high angle limit is 40.5° for molybdenum. Spacings may be read to 0.01 Å. at low angles and, due to a change in scale, to 0.001 Å. at high angles, the $K\alpha_1$ and $K\alpha_2$ curves being plotted separately beyond a Bragg angle of 21° . The charts are intended for rapid determinations of lattice spacings in routine powder analysis, and they are admirably suited for this purpose. A still more open scale for lattice spacing might, however, have been used with some advantage at the very high angles, where the slope of the curves is sometimes as little as one part in forty.

The bulk of Vol. 2 consists of tables of $\frac{\lambda\sqrt{h^2+k^2+l^2}}{2}$

for the $K\alpha_1$, $K\alpha_2$ and $K\beta_1$ radiations of copper, nickel, cobalt, iron and chromium. The tables will shorten considerably the labour of calculating cubic lattice parameters, and, as they are given to six decimal places, they are suitable for work requiring high accuracy. Tables of $\sin^2\theta$ and of the Nelson and

Riley function $\frac{1}{2}\left(\frac{\cos^2\theta}{\theta} + \frac{\cos^2\theta}{\sin\theta}\right)$ are useful additions to the volume. A table of lattice constants of cubic

substances, due to Frevel, may be somewhat misleading as it is by no means complete. For example, although the β -brass and related structures are listed, the complex γ -structures in alloys are omitted as also are the α - and β -manganese structures.

I. G. EDMUNDS

Crystal Structures

By Ralph W. G. Wyckoff. Vol. 3. Pp. xi+641. 14.50 dollars. Second Supplement. (Supplement to Chapter 13.) Pp. 148. 4.00 dollars. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1953.)

THE appearance of Vol. 3 of this work marks the end of the first stage of the task which Dr. Wyckoff has set himself—the presentation of the whole of the results of crystal-structure determination. The two previous volumes (see *Nature*, 169, 681; 1952) were concerned with inorganic and some organic structures; the present volume is confined to organic structures, and, with the addition of the earlier organic section (Chapter 13), provides a complete review of organic structures up to about the middle of 1952.

The loose-leaf form of publication makes the removal of chapters in this way quite possible, and also allows the introduction of supplements, one of which is published together with Vol. 3. This supplement brings up to date some of the information in Vol. 2, and two more Chapters, 11 and 12, remain to be included.

The results are clearly set out, with brief descriptions of the various structures, tables of atomic parameters, drawings, and references. The drawings are of two types—schematic ones, showing the heights of the atoms above a reference plane, and perspective ones, showing the packing of the atoms, which are represented as shaded spheres. These latter drawings are often very beautiful; but it is questionable whether the information they provide justifies the work of preparing them; the more complicated molecules look quite bewildering.

It is a pity that the price of the book is so high. In particular, the supplement, consisting of relatively few pages without any binding, is very costly.

The Measurement of Particle Size in Very Fine Powders

Four Lectures delivered at King's College, London. By Dr. H. E. Rose. Pp. 127. (London: Constable and Co., Ltd., 1953.) 9s. net.

THREE properties, which Dr. Rose terms primary characteristics, are of importance in many industrially significant dusts and powders; they are size frequency, specific surface and particle shape. In his lectures, Dr. Rose is concerned mainly with the determination of particle size and size frequency and subordinately with specific surface. He refers to most of the techniques available for particle-size determination in powders within the size range 1 to 60 microns and discusses simply, but adequately, the theoretical principles of the various techniques and their practical application and limitations. The photo-extinction method, in which Dr. Rose is particularly interested, receives, rather naturally, more detailed treatment than other methods. He refers, also, to some of his own research work.

The lectures are interestingly written; the illustrations are clear; the equations are easy to read; and the whole forms a satisfying small book which should prove valuable not only to those with experience in

this field but also to newcomers, especially in helping to solve the problem of selection of the best method of particle-size determination for a particular powder or dust.

STACY G. WARD

Physical Formulae

By Dr. T. S. E. Thomas. (Methuen's Monographs on Physical Subjects.) Pp. vii+118. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1953.) 8s. 6d. net.

DR. THOMAS'S little book contains many of the more important results in statistics and classical physics. The chief criticism is that it is out of place in a series intended to supply science students at university-level with a compact statement of the modern position in each subject; and that it would have been entirely in keeping with this intention if it had dealt equally generously with modern physics.

G. R. NOAKES

Mechanics

(Lectures on Theoretical Physics, Vol. 1.) By Arnold Sommerfeld. Translated from the fourth German edition by Martin O. Stern. Pp. xiv+289. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1952.) 6.50 dollars.

THE appearance of this English translation makes a valuable addition to the books now available to introduce students to mechanics as a live subject. The contents of this volume have already been discussed in a review of the German edition (*Nature*, 168, 887; 1951); but it is worth stressing again the value of this introduction as a counter-weight to the tendency, so widespread in the teaching, particularly in English schools, of regarding mechanics merely as a branch of mathematics. The lively and readable style of the book has not been lost in translation. The book covers the contents of a normal university course in mechanics. The numerous examples with aids to their solution are all designed to bring home important points of principle, and none of them is of the 'ladder leaning against a wall' type, which is more suited to traditional examination papers than to develop an understanding of the subject.

This book, like the others in the same series, will help to make available to the prospective theoretical physicist the insight and the experience of one of the most successful and inspiring teachers.

R. E. PHIBBS

Principles of Modern Acoustics

By Prof. George W. Swenson, Jr. Pp. vii+222. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1953.) 30s. net.

IN this book the subject of acoustics is considered as the study of inter-related electrical, mechanical and acoustical systems as applied to the production and reproduction of sound, and, as may be expected, great use is made of analogies, especially in the discussion on electroacoustics.

For a thorough study of the analysis and description of acoustical phenomena it is, as the author quite rightly recognizes, very necessary to approach the problem from the mathematical angle. This is what is done in this book, and for those students who can think, reason and understand in terms of mathematical equations and deductions it will be helpful, for the author starts from first principles and his exposition is clear. It is not the book, however, for those students who require a general description of acoustical phenomena and devices and who are

satisfied with simply expressed explanations without the backing of mathematical theory.

In view of the space at his disposal the author has wisely decided to confine himself to the general methods of analysis, illustrated by application to a few typical devices.

A list of standard treatises on acoustics, mechanics and electricity is given in the many footnotes, and these should be of great service to those students who wish to pursue the study of particular topics to a further stage. T. M. YARWOOD

Methods of Mathematical Physics

Vol. 1. By R. Courant and D. Hilbert. (First English edition translated and revised from the German Original.) Pp. xv+561. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1953.) 9.50 dollars.

ENGLISH translations of standard German books are always welcome, and in view of the current demand for mathematics in scientific and technical applications it is particularly pleasing to have this translation. The original text was reviewed at length in *Nature* (153, 633; 1944) by Prof. Milne-Thomson, and readers are referred to this for details concerning the present volume. For the translation, it is sufficient to say that there are numerous additions and modifications, the most extensive of which is an appendix (to Chapter 7) by Wilhelm Magnus. This concerns the transformation of spherical harmonics. A pleasing feature is that the bibliography has been brought up to date. The printing is excellent.

L. S. GODDARD

Electrostatique et Magnéto-statique

Par Émile Durand. Pp. xii+774. (Paris: Masson et Cie., 1953.) 6335 francs.

THIS work is an uneasy compromise between a text-book and a reference book. Students who like spoon-feeding will be delighted by the author's painstaking elaboration of the subject and discussion of many examples in which all calculations are given to the last detail. Experimental physicists and engineers will find in it a wealth of up-to-date information about the mathematical basis of the most varied applications of the electrostatic and magneto-static fields. But one should not look in it for a deeper treatment of the fundamentals of the subject.

Within these limitations this book will certainly be very useful and can be warmly recommended. It is, of course, difficult to be original in treating such a classical subject, and the author's exposition follows the traditional lines. Nevertheless there are a few happy innovations. The Giorgi system of units is consistently used and many tables of typical constants are given, probably for the first time, in these rational units. An interesting chapter describes in a very practical spirit the numerical methods of calculation of field distributions. The treatment of the magnetic properties of matter, and especially that of ferromagnetism (a domain to which the French school has made a brilliant contribution), is particularly well done.

Although the exposition is generally clear, the style is rather pedestrian and there is no sparkle in the book of that elegance which used to be characteristic of the French scientific tradition. It was a shock to discover that the author is so estranged from this tradition that he barbarously denotes the tartaric rendered famous by Pasteur as "sel de Rochelle". L. ROSENFELD

Radioactivity and Radioactive Substances

By Sir James Chadwick. Fourth edition. Pp. xv+120. (London: Sir Isaac Pitman and Sons, Ltd., 1953.) 12s. 6d. net.

THIS text-book has stood the test of time and in spite of the remarkable developments in the field of nuclear physics during the past fifteen years it still remains one of the best introductions to the fundamentals of the subject. It was first published in 1921 and has now reached the fourth edition. The arrangement of the material in the new edition is substantially the same as that in the original edition, but where necessary the subject-matter and data have been modified or supplemented to bring it up to date. In the chapter on measurements more modern methods and techniques have been introduced and a new chapter on nuclear structure, in which nuclear stability, artificial radioactivity and nuclear fission are discussed, has been added. These revisions and additions are by Prof. J. Rotblat, who it will be remembered worked for many years at Liverpool under Sir James Chadwick and who is thus well qualified to revise a book originally written by Sir James. S. WEINTROUB

Optics

The Technique of Definition. By Arthur Cox. Tenth edition. Pp. 376. (London and New York: The Focal Press, 1953.) 17s. 6d. net.

IF the popularity of a book can be judged by the number of editions published, then this book must indeed be very popular, for it now appears in its tenth edition, the first having been published in 1943.

The work is devoted entirely to what are undoubtedly the most precious and vital parts of any camera, namely, lenses, and the subject is treated very exhaustively and thoroughly, in a language which the ordinary photographer can understand without becoming involved in scientific formulae.

The full study of lenses is admittedly highly technical; but the treatment here is so skilfully done that the reader cannot fail to become intensely interested, and he soon finds himself able to understand how his lens works and why, what may be expected of it and what is the best type to use. The gap between the scientific approach of the designer and the practical man who uses the lens has been bridged, and the photographer can now have an added zest and intelligence for his work, based on a more intimate knowledge of his chief tool.

It is not only the photographer who can derive benefit from the book. There are also excellent articles on the defects of lenses, such as aberrations of various types, distortion, etc., which will be found useful to any student of optics whether interested in photography or not. T. M. YARWOOD

Advances In Applied Mechanics

Edited by Richard von Mises and Theodore von Kármán. Vol. 3. Pp. x+324. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1953.) 9 dollars.

THIS third volume carries on the admirable tradition already established. The present book is almost entirely devoted to problems of fluid dynamics except for a long, careful, interesting and important article by Dr. Geiringer giving a very comprehensive account of some recent results in the theory of an ideal plastic body. There is also a short

article by Albert I. Bellin on recent work on non-linear differential equations of the second order.

G. F. Carrier gives an account of some boundary layer problems in oceanography, in heat transfer and in electrical relaxation oscillations. Zeldastani describes recent work which extends and generalizes the classical researches of Riemann on one-dimensional isotropic fluid flow. The problem of diffusion through a field of homogeneous turbulence is studied by F. N. Frankiel. H. F. Ludloff deals with the aerodynamics of blasts and G. Guderley with the presence of shocks in mixed subsonic-supersonic flow patterns. A short and useful article by L. Rosenhead gives a critical summary of most of the theoretical and experimental papers which have been written about wakes for Reynolds numbers less than 2500.

There is no doubt that this series of reports has become indispensable to research workers in applied mechanics. Perhaps it is not out of place to take this opportunity of recording the gratitude which all readers must feel to one of the editors, Prof. Richard von Mises, who died a short time ago, and to whose scholarship and vision we owe so much.

G. TEMPLE

The Great Palomar Telescope

By Helen Wright. Pp. 176+15 plates. (London: Faber and Faber, Ltd., 1953.) 12s. 6d. net.

AS an astronomer's account of the 200-in. telescope, written for the general reader, Miss Helen Wright's book is very satisfying. The instrument and its observatory are described fully, with many photographs and line drawings. There is an introductory chapter on the evolution of the telescope and the spectroscope, and an outline of the progress which had been made with the aid of the Mount Wilson 100-in. reflector up to about 1936. It is a book one would recommend strongly for inclusion in, say, a school library; and it would certainly be appreciated by the young science student.

Miss Wright writes with a lively journalistic manner. Except during the hiatus of the war years, indeed, the progress of the telescope was news, often quite exciting news. The atmosphere of mounting public interest is recaptured here, for reporting was immediate and full. The technical problems that were faced are described clearly in less vivid terms. Dr. G. E. Hale, who lived to see the major difficulties surmounted but not the completion of the work, is the central character of the story. But the adventures of the telescope itself, starting with the financial crisis of 1929, beset by floods at the Corning Works during annealing, pursued during the last journey to the observatory by hazards of ice and blizzard, speak of the effort and determination contributed by all engaged in the work. The author's treatment of the human side of the enterprise adds greatly to one's enjoyment of the book.

G. R. NOAKES

Linear Algebra and Projective Geometry

By Reinhold Baer. (Pure and Applied Mathematics Series, Vol. 2.) Pp. viii+318. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1952.) 6.50 dollars.

TWENTIETH-CENTURY mathematics shows a change of trend away from the details of particular theorems towards abstraction and the analysis of structure. The object of the book under review is to prove the essential structural identity of projective geometry and linear algebra. The author

has gathered together much material difficult of access elsewhere and supplemented it by his own researches. To a geometer of the older type the result is by no means easy reading. He will find little or no opportunity to use his geometric intuition; but a constant need for a good grasp of the concepts of abstract algebra. He may imagine that the author's object is not so much to prove the equality of projective geometry and linear algebra as to reduce the former to a satellite of the latter. However, to those who accept the abstract point of view the book has many merits. It deals with the representation of projective geometries by linear manifolds, of projectivities by semi-linear transformations, of collineations by linear transformations, and of dualities by semi-bilinear forms. Thus the geometry with which the discussion starts is reconstructed within such apparently purely algebraic structures as the endomorphism ring of the underlying linear manifold or the full linear group. The book contains seven chapters, and concludes with an appendix on the theory of sets, a bibliography, and an index.

H. T. H. PIAGGIO

Pages choisies d'analyse générale

Par Maurice Fréchet. (Collection de logique mathématique, Série A, No. 3.) Pp. 214. (Paris: Libr. Gauthier-Villars; Louvain: E. Nauwelaerts, 1953.) 000 francs.

'GENERAL ANALYSIS' is usually associated with the name of the American Prof. E. H. Moore, whose researches began in 1906, but actually those of Prof. M. Fréchet began two years earlier. Both sought to generalize the classical theory of functions of real variables and Cantor's theory of sets, but Moore was influenced by algebra and integral equations, while Fréchet was influenced by geometry. For several years these two authors developed the subject on somewhat different lines; Moore pointed out that Fréchet's approach was more abstract and more general than his own. Prof. Fréchet intended to write a book on general analysis as a sequel to his book on abstract spaces, but his appointment as professor of the calculus of probabilities diverted his interests. Now, after many years, he has been persuaded to collect and republish the most important of his papers on general analysis, some of which, scattered among the periodicals of several countries, had become almost inaccessible. The papers have been arranged in logical (not chronological) order, sometimes shortened, and grouped into chapters, supplemented by references to later developments by other authors. This has produced something very much like the book for which his friends and pupils had waited so long. The first chapter gives a general outline of the subject, the second deals with functional spaces, and the third with functional analysis. The fourth chapter introduces abstract spaces; the fifth and last, general analysis.

H. T. H. PIAGGIO

Foundations of Algebraic Topology

By Samuel Eilenberg and Norman Steenrod. (Princeton Mathematical Series.) Pp. xv+328. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1952.) 48s. net.

THIS book presents, for the first time, an axiomatic treatment of the complete transition from topology to algebra. Chapter 1 gives the axioms for a homology theory, and a set of general theorems deducible from them. Chapter 2 deals with simplicial complexes and triangulable spaces. In Chapter 3, a

homology theory is assumed given on triangulable spaces; the classical algorithms for computing the homology groups of a complex are then derived from the axioms, and using these, the axioms are shown to be categorical for homology theories on triangulable spaces.

Chapter 4 presents the concepts of category and functor. Chapter 5 makes the step from chain complexes to homology groups. Chapter 6 gives the classical homology theory of simplicial complexes, while in Chapter 7 the singular homology theory is defined and shown to satisfy the axioms. In Chapter 8, direct and inverse systems of groups and their limit groups are considered, as an algebraic preliminary to the development of the Čech homology theory given in Chapter 9; additional properties of the latter are set out in Chapter 10, where it is seen that the addition of a single new axiom characterizes the Čech theory on compact spaces. Two additional homology theories are constructed which are extensions of the Čech theory on compact spaces.

Chapter 11 gives classical applications of homology theory, including the Brouwer fixed-point theorem, invariance of domain, and the fundamental theorem of algebra. The authors state that a second volume is in preparation. The book is excellently written from the axiomatic point of view. R. G. COOKE

Description of a Magnetic Drum Calculator

By the Staff of the Computation Laboratory. (Annals of the Computation Laboratory of Harvard University, Vol. 25.) Pp. xi+318. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1952.) 52s. net.

THE publication of complete design information about a large automatic computing machine is something of a problem, partly because of the speed at which the subject has developed in the past decade and partly because of the magnitude of the task. As a result all too few computers are as fully documented as those designed and built at the Harvard Computation Laboratory. Four Harvard machines are now in existence. Mark I, also known as the Automatic Sequence Controlled Calculator, was completed in 1944 and is still in use at the Laboratory. Mark II was completed in 1948 and has since been in operation at the U.S. Naval Proving Ground, Dahlgren, Virginia. Mark III, which forms the subject of this volume, was the first of the series to make use of electronic techniques; it began to operate on a production basis at Dahlgren in 1951. Since that time development has continued and a further machine, Mark IV, has been built and is now working at Harvard.

Much of the logical design of Mark III matches the distinctive pattern established by its two predecessors. The decimal scale is used, and numbers are stored quite separately from instructions. This was one of the earliest machines to employ magnetic drums for internal storage and to exploit the possibilities of magnetic tape as an input/output medium. The nine drums were carefully engineered and use a rather conservative pulse density. A certain amount of checking equipment is built into the machine, which uses a word length of sixteen decimal digits.

Most of this book is devoted to details of the logical design, engineering and circuits of the machine. These are very fully covered and well illustrated. A description of how problems are prepared and presented to the computer is also given, together with some simple examples. E. N. MURON

Typical Means

By Prof. K. Chandrasekharan and Prof. S. Minakshisundaram. (Tata Institute of Fundamental Research Monographs on Mathematics and Physics, 1.) (Published for the Tata Institute of Fundamental Research, Bombay.) Pp. xi+140. (London: Oxford University Press, 1952.) 35s. net.

OF the numerous methods devised for dealing with oscillatory series, one of the most important is by the use of M. Riesz's 'typical means'. The first systematic account of what Prof. G. H. Hardy described as 'his beautiful theory' appeared in Hardy and Riesz's Cambridge Tract "The General Theory of Dirichlet's Series" in 1915. Since that time the subject has developed considerably. The book under review gives a comprehensive account, including a good deal of material hitherto available only in research periodicals and even some still unpublished when the book appeared. The first and second chapters deal with the general theory, including theorems of consistency and Tauberian theorems. The third chapter applies this theory to Dirichlet's series. The fourth chapter applies it to Fourier series, starting with a theorem due to S. Bochner on multiple Fourier series and including several results due to Prof. Chandrasekharan himself. A valuable feature of the book is the supplementing of each chapter by extensive bibliographical notes.

H. T. H. PIAGGIO

Stochastic Processes

By Prof. J. L. Doob. (Wiley Publications in Statistics.) Pp. vii+654. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 80s. net.

THIS text is important for at least two reasons. It meets a long-felt need for a systematic account of a subject which has grown rapidly during the past 20-30 years; and it is an account in English of a subject which has developed largely outside the English-speaking world. Readers for whom the Russian language is a closed medium will find here accounts of contributions by Gnedenko, Khintchine, Kolmogorov, Krein and other Russian authors.

There is an introductory chapter on elementary definitions and theorems in probability theory, but, as Prof. Doob points out, "there has been no compromise... probability is simply a branch of measure theory... and no attempt has been made to sugar-coat this fact". This attitude, indeed, sets the flavour. The reader who is not a specialist in measure theory will find the going heavy in places, but he may be consoled by the fact that there is a supplement on measure theory. After three chapters dealing with stochastic processes in general there come two chapters on Markov processes. In the first of these there is a lucid account of finite-dimensional Markov chains with an application to card shuffling. In the second there are applications to diffusion equations, including the Fokker-Planck equation occurring in various physical problems. Next comes a long chapter on martingales with an application to games of chance. Later, there are chapters on stationary processes, and the book ends with a chapter on linear least-squares prediction.

It is perhaps worth emphasizing that the present work is mathematical rather than applied in character, in the sense that mathematical formulation and method take precedence over the details of applications. L. S. GODDARD

Sampling Methods for Censuses and Surveys

By Frank Yates. Second edition, revised and enlarged. Pp. xvi+401. (London: Charles Griffin and Co., Ltd., 1953.) 38s. net.

THIS book, first reviewed in *Nature* (166, 245; 1950), has an established place as an authoritative manual on the general subject of sampling. The author now has more to say, sometimes by way of commentary on or expansion of what was in the first edition, but mostly by way of new material and developments. He has chosen to leave the eight chapters of the first edition unaltered, except for the insertion of references to the added material, and to add two new chapters. Chapter 9 consists of a series of further notes on the critical analysis of survey data. Broadly, these deal with general questions such as contrasts between domains, or the relative precision of different methods of sampling, especially when domains of study cut across strata; but the opportunity is taken to supplement an earlier treatment of simple regression by describing briefly the multiple regression procedure, and by showing how this concept is to be interpreted in terms of caustic systems. Chapter 10 deals with a number of miscellaneous developments. Modern machines for use in computation and census work are referred to, but so briefly that legitimate curiosity is not satisfied; most of the remainder concerns varied methods of sampling, of which lattice sampling may be singled out as an ingenious way of incorporating the same sort of advantages into sampling that are gained by designing agricultural and other experiments on such patterns. The book is brought up to date by a description of the sampling method used for speeding up the reporting of the results of the 1951 Census.

The author is to be commended on his industry in coping with a very intricate subject in such painstaking detail. The result, however, is a book that is by no means a delight to read, for the style is heavy and, in places, obscure. A most complicated notation means that the reader must not allow his attention to wander. For his sake it is a pity that the author has at times forgotten the rigours of his own notation, for example, on p. 298 in quoting a formula in words in the text, while he might have avoided adding to the confusion by using the first two letters of the alphabet in different senses in the same formulae, as he does on pp. 318-19.

J. WISHART

Cambridge Elementary Statistical Tables

By D. V. Lindley and J. C. P. Miller. Pp. 36. (Cambridge: At the University Press, 1953.) 6s. net.

THE statistical material in this set of tables consists of the normal, t , χ^2 and variance ratio distributions, the r - s transformation, factors for converting range to standard deviation, and random numbers, occupying in all ten pages. The remaining twenty-two pages are taken up by tabulations of x^2 , $\sqrt{x}$, $1/x$, $1/\sqrt{x}$, $\log x$, $\text{antilog } x$, $\sin^{-1}\sqrt{x}$, $\sinh^{-1}\sqrt{x}$, $\log n!$ and a one-page table of proportional parts from 2-99 (surely unnecessary).

The printing, binding and layout reach that high standard which one would expect from collaboration between the authors and the Cambridge University Press, and the price is such that the tables should, as the authors hope, be useful for students in schools and universities, and for the research worker who requires a handy set of tables for the occasional normal, t , χ^2 or F test. But one could have wished

that the statistical material had been treated a little more generously to the exclusion of material adequately covered by ordinary four-figure mathematical tables. Fisher's original tables of t and χ^2 covered the whole range of P , and z has since been extended in a similar manner. The central values have their uses, both for the student and research worker. The table of percentage points of the normal distribution might well be fuller, and possibly that of the ordinates also, and one misses a table of significance levels of r , which gives a quick test of association between two variates. Random permutations also have a claim to inclusion. The preface is confused on the relation between one- and two-tail tests, and thus, perhaps, has led to a rather curious choice of significance levels. Finally, the reviewer, at least, is left wondering why the non-statistical functions are all presented together instead of separately on pairs of pages.

F. YATES

The First Fifty Years, 1903-1953

Edited by F. I. G. Rawlins. Pp. xv+86+11 plates. (London: The Faraday Society, 1953.) Cloth 10s. 6d.; Leather 21s.

THIS little book is not a set piece; it is more in the nature of a birthday book in which people have been good enough to write interesting things about the Society, now on the threshold of its fiftieth anniversary; in these words, the editor, Mr. F. I. G. Rawlins, describes the purpose of the volume under review.

The Faraday Society occupies a unique position in the chemical world; it has fostered the study of physical chemistry in all its branches, first, by providing, in its *Transactions*, a medium for the publication of physico-chemical research, and secondly, and perhaps this has been its most important, as it has certainly been its unique, contribution, by organizing the famous 'General Discussions'. These symposia on current topics have been characterized by timeliness, and few of them have not been followed by a real reorientation of thinking on the subject under discussion. In addition, these discussion meetings have been notable social occasions; the editor says that he and the other contributors to the present volume have been "trying to enjoy ourselves"—not a difficult task for regular attenders of the Society's discussions.

It is most fitting that the first article in the book is a chapter of personal reminiscences by Prof. F. G. Donnan, since he has probably done more than any other single man to guide the Society along the right paths during its first fifty fruitful years; the other thirteen chapters give the reader a valuable and interesting bird's-eye view of the development of physical chemistry between 1903 and 1953. Mr. Rawlins need have no doubt that this book does indeed "demonstrate that the Faraday Society is a living organism, continually emitting and receiving new knowledge on its way towards equifinality"; long may it remain so.

H. N. RYDON

The Art of Scientific Investigation

By Prof. W. I. B. Beveridge. Second Edition. Pp. xii+176+5 plates. (London: William Heinemann, Ltd., 1953.) 10s. 6d. net.

PROF. BEVERIDGE, in preparing the second edition of his book on the methods and results of scientific investigation, has made some minor revisions and partly re-written the chapter on reason. Essentially, however, the book remains as reviewed in our columns on March 3, 1951. A. S. PARKES

INSTRUCTIONAL FILM RESEARCH IN PENNSYLVANIA

ACCOUNTS of the early reports of the Pennsylvania Instructional Film Research Program have already been given in *Nature*^{1,2}, and it is the purpose of this article to review shortly some further Pennsylvania reports* now available in Great Britain. In every Pennsylvania experiment in which the learning results have been objectively assessed, people have learned from the films shown them³. Many of these further studies confirm that films can teach effectively, and though this, in fact, is usually discovered incidentally, it is sometimes borne out as the result of the main purpose of an experiment, as in Study 29, which deals with the instructional effect of the film "How to Operate the 16-mm. Sound Projector Set".

Learning from films may be factual learning or motor perceptual learning. A group of the new Studies, 25-27, by S. F. Harby, is concerned with the use of film-loops, daylight projected, for the teaching of athletic skills. The film-loop demonstrations were as effective as live instructor demonstrations, the addition of physical practice and coaching to the film-loop demonstrations being advantageous. A directed system of watching the film-loops and of practice was better than leaving the students with no outside guidance.

Mental practice, defined as the symbolic or covert practice of a perceptual-motor skill and described as resulting from trying to "imagine the feel of it", is—according to M. A. May⁴—an ingredient in any film-learning situation. Study 28 compares the effectiveness of mental and physical practice. There is a point beyond which mental practice does not help. Twenty periods of physical practice were significantly more effective than twenty periods of mental practice. Films extend the time learners can and will practise mentally.

A number of earlier findings of the Pennsylvania research are confirmed by the new studies: repeated showings of a film can result in a worth-while increase in learning (Studies 29 and 25-27); increased experience of films in training improves the ability of an audience to learn from films (Study 20, by A. W. Vander Meer); and note-taking during the showing of films interferes with learning (Study 21, by Ash and Carlton, and also independently reported⁵).

As in all learning situations, the student who is to learn from films must wish to learn and perceive relevance in what is put before him. A number of the new studies deal with the motivation of the student towards learning, with his participation and involvement, and Study 24 shows that anxiety—fear of the consequences of failing in a test of knowledge gained from a film—leads to increased learning. The advantages of a pre-film test of performance and of factual knowledge are shown by Studies 29 and 35, and of providing the correct answers to all test-questions—rather than merely informing a student that he is right or wrong—by Study 30. Study 33 shows that written titles making plain the 'organizational outline' of a film increase learning, particularly for the less intelligent.

A further comparison of black-and-white and colour films (Study 28) shows that colour makes a

contribution to retention of what is learnt rather than to learning itself, but this contribution does not seem to be large enough to justify the additional cost of coloured films. The single Study (32) so far carried out on stereoscopic films shows no advantage in stereoscopy.

Study 23, "Film Profiles", by Loran Twyford, in examining the value of subjective evidence, has some general psychological interest and is also of interest because it may lead to a change in the method of film investigations. The popularity of a radio programme has often been assessed by what is called 'a rating profile', a profile based on polygraph recordings of the responses of a sample audience, peaks in the profile representing sections of the programme to which a large number of the audience respond positively. Would the rating of an instructional film based on positive responses 'I am learning' and negative responses 'I am not learning' be a valid rating of learning? It was found in the Pennsylvania experiments that the subjectively based profile was, in fact, correlated highly with an 'objective test' profile, and in another film investigation, outside Pennsylvania, the subjective judgment of an audience has appeared similarly valid⁶.

Report 31, by the director of the Pennsylvania research, is largely a more positive statement of principles previously put forward as "trends of results". In general, the sixteen studies reviewed confirm and refine earlier results, although a first experiment on stereoscopic films has been made, and a fresh finding may lead to a change in the method of film investigations.

REDUCTION BY X- AND γ -RAYS OF SOME SUBSTANCES OF BIOLOGICAL INTEREST

By DR GABRIEL STEIN*

and

DR A. J. SWALLOW†

Department of Radiotherapeutics, University of Cambridge

IT is usually considered that the main primary effect of ionizing radiations on aqueous solutions is to form hydrogen atoms and hydroxyl radicals¹. In the presence of a solute which can be oxidized in two steps, the hydroxyl radicals may react according to:

We wish to present a number of instances where a second solute is introduced in a concentration so small that the AH_2 protects it from hydroxyl radicals, and the effects observed on the second solute must be due to the action of AH radicals or hydrogen atoms, or both.

* Technical Reports S.D.C. 269-7-80 to S.D.C. 269-7-85 of The Instructional Film Research Program, The Pennsylvania State University, U.S.A.

* Permanent address: Department of Physical Chemistry, Hebrew University, Jerusalem, Israel.

† I.O.I. Fellow, University of Cambridge.

Sources of radiation included cobalt-60 γ -rays, 220 kVp. X-rays filtered through 1 mm. aluminium, and unfiltered 200 and 190 kVp. X-rays. Dose-rates with γ -rays were 7-12 r./min. and with X-rays 500-3,000 r./min. Doses were of the order of 30,000 r. Temperatures were 20-40° C.

Methylene blue. In air-free solutions in the absence of other organic solutes, the decoloration of methylene blue (10^{-4} M) by X-rays is partly a reversible reduction and partly an irreversible oxidation². Addition of 0.5 M sodium benzoate results in an increased rate of decoloration, which is now entirely due to a reversible reduction. The addition of ethanol has a similar effect³.

In the presence of dissolved air, the reversible reduction cannot be demonstrated, and the irreversible oxidation can be prevented by sodium benzoate, which in this case is acting as a protective agent in the sense employed by Dale⁴.

Coenzyme 1. The irradiation with γ -rays of air-free aqueous solutions of coenzyme 1 (3×10^{-4} M, pH 7.8) in the presence of 0.5 M ethanol results in a yield of acetaldehyde three times greater than in the absence of coenzyme 1, and a substance with an absorption band at 340 m μ is formed⁵. This substance is also formed with X-rays at both pH 7.8 and 10.4, and tests with lactic dehydrogenase have shown that it is not identical with coenzyme 1 reduced enzymatically, and also it does not exhibit the characteristic whitish fluorescence of this compound. The irradiation product resembles the enzymatic product in that further irradiation changes the absorption curve in the same way, both substances slowly reduce methylene blue, and both absorption curves shift in the same way on addition of acid⁶. It may be that the irradiation product is identical with one of the substances made by reducing coenzyme 1 with sodium borohydride⁷. The irradiation product appears in the presence of 0.5 or 0.01 M β -hydroxybutyrate, *n*-propanol, *iso*-propanol or allyl alcohol. It is produced in 0.01 M but not 0.5 M solutions of lactate. No product appears at either concentration in solutions of benzoate, succinate, glucose or maleate⁸. None of the product appears in air-free solutions of coenzyme 1 alone or when hydrogen is present. In the presence of dissolved oxygen, the product could not be observed in the presence of any added substance.

Nicotinamide-methochloride. In order to obtain further information about the nature of the irradiation product of coenzyme 1, we have irradiated aqueous solutions of nicotinamide-methochloride with X-rays, and have found that in the presence of ethanol its radiation chemistry is similar to that of coenzyme 1⁹. The irradiation product (which absorbs at about 360 m μ in this case) has been extracted from the irradiated solution and found to have an absorption spectrum different from that of Karrer's N-methyl-*o*-dihydronicotinamide¹⁰; but it changes in the same way on addition of acid (Fig. 1). The product has a much weaker fluorescence than Karrer's N-methyl-*o*-dihydronicotinamide; it reduces silver nitrate instantaneously in the cold and decolorizes methylene blue at the same rate as Karrer's substance. The product does not appear when pure nicotinamide-methochloride solutions are irradiated in the presence of molecular hydrogen, or when pure solutions are irradiated in the absence of oxygen. In the presence of dissolved oxygen, the product does not appear whether ethanol is present or not.

Fig. 1. Irradiation of nicotinamide-methochloride. Absorption curve of irradiation product (0.03 mgm./ml.). x—x, pH 11.0; ●—●, after acidification.

The structure of the irradiation product is not yet certain, but there are three positions in the pyridine ring at which reduction is possible¹¹. Karrer's N-methyl-*o*-dihydronicotinamide corresponds to one of the positions, and this is also the position at which reduction takes place when coenzyme 1 is reduced enzymatically. Karrer *et al.* have also prepared an N-methyl-dihydronicotinamide, which is stable to the addition of acid, and this corresponds to reduction at a second position¹². It seems possible that our product has been reduced at the third position.

Cytochrome c. The irradiation with X-rays of cytochrome c (10^{-3} M) in air-free solutions containing 0.5 M benzoate or succinate leads to a product which exhibits the typical absorption spectrum of reduced cytochrome c. The product can be reoxidized by ferriocyanide, and it reacts with the complete enzyme system of heart-muscle preparation, as does reduced cytochrome c which has been produced by, for example, hydrosulphite. If, however, methanol, ethanol, *n*-butanol or dissolved molecular hydrogen are used instead of benzoate or succinate, the irradiated solution contains a reduced product which can be oxidized with ferriocyanide; but both irradiated and reoxidized solutions have an absorption spectrum different from normal cytochrome c (Fig. 2)¹³. This latter spectrum is also obtained in a lower yield in air-free solutions containing cytochrome c alone.

The results given above show that organic additions do not all result in the same reactions on irradiation. This indicates that specific differences exist in the behaviour of the organic AH radicals, in broad agreement with the conclusions drawn by Mackinnon and Waters¹⁴.

The absence of any reduction in the presence of dissolved oxygen¹⁵ can be ascribed to the formation of peroxides by hydrogen atoms and AH radicals. It should be noted that AH radicals have been postulated as intermediates in some enzyme reactions^{11,12}, and the reactions we have described may be of interest in this connexion¹⁶.

In aerated solutions organic additions often exert a protective effect⁴. It is significant that in the present type of system organic additions can serve as potentiating agents; the effects of the radiation thus manifest themselves in good yield on components

Fig. 2. Irradiation of cytochrome *c* in presence of ethanol. ●—●, absorption curve of irradiated solution after ferricyanide oxidation of reduced cytochrome *c*. ×—×, control cytochrome *c*.

present in very low concentration. Moreover, in the case of coenzyme 1 and under certain conditions with cytochrome *c*, the product is not identical with the enzymatic product, and essential components of enzyme systems have thus been inactivated. It may be significant that Holmes¹⁴ has found that in some irradiated biological systems the coenzyme 1 appeared to be the factor inactivated.

We wish to thank Dr. M. Dixon, Dr. E. Margoliash and Mr. R. P. Scutt for gifts of materials and valuable advice, and Prof. J. S. Mitchell for his interest. One of us (G.S.) is indebted to the Humanitarian Trust and the Friends of the Hebrew University for a grant. [Jan. 14.]

A NEW CYTOCHROME IN LIVING ROOTS

By PROF. H. LUNDEGÅRDH

Institute of Plant Physiology, Uppsala 7

THE absorption spectrum of bundles of living roots of wheat and other cereals reveals the existence of a complete cytochrome system¹, composed of prosthetic groups similar to the cytochromes *a*, *c* and *b* of animal tissues and many micro-organisms². The system is responsible for 50–75 per cent of the total aerobic respiration, and it oxidizes succinate. The system has been studied in detail by means of a very sensitive new spectrophotometric

technique. Already the preliminary experiments with increasing levels of reduction have indicated the appearance of a new band at 570–575 mμ after prolonged anaerobiosis. It was tentatively concluded that this band belongs to an enzyme of lower oxidation-reduction potential state than cytochrome *b* and is possibly identical with succinic dehydrogenase. On continued investigation of the absorption spectrum, it has now been found that what was hitherto believed to be a joint *γ*-band of cytochromes *c* and *b* is in fact due to three cytochromes, and that one fraction of the joint band with its peak between *c*. 420 and 430 mμ belongs to a substance also characterized by the *α*-band at 571 mμ. The substance thus behaves as a true cytochrome and may be provisionally named cytochrome *dh*.

Time-course of Reduction of Cytochromes *b* and *dh*

Even if the joint *γ*-band of cytochromes *b* and *dh* occasionally shows a twin peak, no significant conclusions as to the existence of a new cytochrome can be drawn from the shape of the band only (cf. ref. 3,

Fig. 1. Difference spectrum between roots under anaerobiosis and in aerated salt solution. The upper curves show the increasing reduction of the cytochrome system after stopping the flow of the solution. — after 3 min. (cytochrome *c* already completely reduced); after 7 min. (joint band of *b* and *dh* with its peak near 563 mμ); ——— after 12 min. (the peak of the joint band more toward 571 mμ); ——— after 45 min. (complete reduction; cytochrome *c* recognized as a hump at 550 mμ, joint band of *b* and *dh* with the latter dominating; *β*-band of *b* visible).

The lower curves show the increasing reoxidation after switching on the flow of aerated solution. — after 1 min. (negative bands of *c* and *b*); ——— after 2½ min. and ——— after 5 min. (oxidation complete, joint band of *b* and *dh* moved to the right).

p. 103). Conditions must be chosen under which the steady states of cytochrome *b* and of the new cytochrome behave differently. Two ways have been tested, namely, the time-course of increasing reduction or reoxidation, and the use of specific inhibitors.

By means of the new recording technique, it can be shown that in the course of increasing reduction, beginning from the predominant oxidation in an aerated dilute salt solution, the peak of the joint γ -band moves from c. 431 m μ to c. 437 m μ , whereas the α -bands to the right of cytochrome *c* begin with a peak at 563 m μ and then extend towards c. 571 m μ (Fig. 1).

From a large number of such series of spectrograms the following figures were computed:

Cytochrome <i>b</i>	431 and 563 m μ (red)
Cytochrome <i>dA</i>	424 and 571 m μ (red)

The shifting of the steady states of the single cytochromes can be conveniently recorded by starting from an aerated solution and simply stopping the flow through the recipient with the roots. A more rapid reduction is attained from starting in an oxygen-free solution of succinate. In this case the process is completed in a few minutes, because now only the quantity of oxygen present in the roots themselves has to be consumed. As shown in a previous communication⁴, the reduction of cytochrome *b* lags behind that of cytochrome *c* and the cytochrome oxidase. The reduction of cytochrome *dA* is still more retarded (cf. Fig. 1).

The steady states appearing when the supply of oxygen is reduced can be more closely studied if

Fig. 2. ——— Difference spectrum of roots under complete anaerobiosis; cytochrome *dA* dominating. - - - - Difference spectrum of the same roots in a dilute salt solution containing 15.7 $\mu\text{mol. l}^{-1}$ oxygen (= c. 5 per cent of the normal tension). Separate bands of the cytochromes *b* and *dA* visible also in the γ -region (the extension of the *dA*-band to the left is caused by the *c* γ -band)

Fig. 3. Difference spectra of roots under complete anaerobiosis (—) and after treatment with 10 per cent urethane (see text). (A) The γ -band of cytochrome *b* in urethane (---) is moved to the right of the combined *b* and *dA* band under anaerobiosis (—). (C) The α -band of cytochrome *b* appears in urethane (---) to the left of the combined *b* and *dA* band under anaerobiosis (—). (B) Difference spectrum between the two curves in C, showing the reduced bands of cytochrome *dA*

the medium is exchanged for flowing solutions having a low constant oxygen pressure. Measurable reduction starts only if the oxygen pressure sinks below c. 10 per cent of the normal equilibrium between solution and air. The situation at a pressure of 5 per cent of the normal oxygen tension is illustrated by Fig. 2. These roots were exceptionally rich in cytochrome *dA*, the bands of which now can be clearly observed in addition to those of cytochrome *b*.

Differentiating Effect of Urethane and Fluoride

Urethane uncouples the electron transfer between cytochromes *b* and *c*, leaving the former in a reduced state, if the roots are treated with oxygen-free 10 per cent urethane and then transferred to aerated urethane (see ref. 3). Because the oxidation-reduction potential of cytochrome *b* is higher than that of cytochrome *dA*, the predominantly reduced *b* is balanced by a predominantly oxidized *dA*. As a consequence of that, the peak of the γ -band is moved from c. 424 m μ to c. 431 m μ and the corresponding peak³ at 571 m μ disappears. The spectrum of cytochrome *dA* can accordingly be calculated from the curves as the difference between anaerobiosis and treatment with urethane (Fig. 3). Besides the peaks at 424 and 571 m μ respectively, the reduced cytochrome *dA* shows a β -band at c. 540 m μ (Fig. 3).

The differentiating effect of fluoride is less distinct than that of urethane. 0.025–0.05 *M* sodium fluoride at pH 3.3–4.0 (cf. ref. 3) oxidizes cytochrome *b* almost completely and cytochrome *dA* to a considerable extent. Its effect is thus the reverse of that of urethane, because fluoride completely inhibits the reduction of cytochrome *b*, that is, the electron transfer from *dA*, and partly also inhibits the activity of *dA* itself. The net result is a shift of the joint reduced γ -bands to the left and of the α -group to the right. In the difference spectrum between roots in aerated water and roots in aerated solution of sodium-fluoride, the reduced peaks consequently

appear at 431 m μ ($\beta\gamma$ dominating), 535 m μ ($\beta\beta$), 550 m μ (α), and 563 m μ ($\beta\alpha$).

The experiments clearly show that fluoride primarily inhibits the transfer of electrons from $d\bar{h}$ to b , whereas cytochrome $d\bar{h}$ can still accept electrons, probably from succinic acid (see below).

Cytochrome $d\bar{h}$ and the Cytochrome System

Like cytochrome oxidase, cytochrome $d\bar{h}$ forms a compound with cyanide. The γ -band is in part moved from 424 to c. 435 m μ and the α -band at 571 m μ is moved to c. 585 m μ . This is the reason why the reduced bands of cytochrome c are 'cleaned' by cyanide (see ref. 3). Also, the bands of cytochrome b are affected by cyanide. The α -bands are weakened; but it is yet not decided if they also are displaced.

The sensitivity of cytochrome $d\bar{h}$ to cyanide is direct evidence against its linkage to the non-cyanide sensitive 'ground respiration'. This conclusion is supported by the observation that the bands are identically affected by cyanide aerobically or anaerobically. The obvious linkage to the succinoxidase system is, on the other hand, illustrated by the fact that reduced cytochrome $d\bar{h}$ is partially oxidized by fumarate (0.1 M at pH 3.3–4.0; see ref. 3) if the roots are held anaerobically, even in the presence of hydrogen cyanide. All the observed facts point in the direction of cytochrome $d\bar{h}$ probably being identical with succinic dehydrogenase.

In the approximate equilibrium between cytochromes b and $d\bar{h}$ attained in urethane (see above), b remains reduced to c. 90 per cent; but $d\bar{h}$ is oxidized to about the same degree. Assuming an oxidation-reduction potential state of 0.14–0.17 V. for cytochrome b (see ref. 3, p. 135), this corresponds to a potential of cytochrome $d\bar{h}$ slightly above zero (0.02–0.05 V.). In the steady states of the normally working cytochrome system, cytochrome $d\bar{h}$ will accordingly be highly oxidized and thus exert a maximum oxidizing effect on succinate. The extremely rapid reoxidation through the whole 'electron ladder' from $d\bar{h}$ to oxygen⁴ supports the conclusion that there is a very low resistance to electron transfer from $d\bar{h}$ to oxygen, the actual turnover at normal respiration being regulated by the slow oxidation of succinate. This process includes the formation of protons and electrons from the hydrogen atoms detached from the succinate. The complete cytochrome system of the roots thus may be pictured in the following way (arrow = electron transfer):

Relative Concentrations of the Haemin Enzymes In Roots and their Relation to the Quantities of Protohaemochrome

Assuming extinction coefficients of similar magnitude to those of cytochrome c (cf. ref. 3), the approximately equal height of the reduced bands of cytochromes $d\bar{h}$ and b points to an approximately equimolar concentration of these two enzymes in the wheat roots. The relation varies somewhat, however, and frequently shows a predominance of $d\bar{h}$ (cf. Fig. 2). The relation between cytochrome b and cytochrome c remains about the same as was earlier calculated, namely, c. 1.75. The fact that the revised

values of cytochrome b are not very far from the earlier calculated values depends upon the shape of the absorption bands in the γ -region. Two similar bands lying at a distance of 8 m μ join to form a single band. Its peak at c. 427 m μ is only about 20 per cent higher than that of the single bands at 424 and 431 m μ respectively.

Wheat roots also contain peroxidase (cf. ref. 5), the concentration of which can be measured from the height of the bands at 404 and 612 m μ of the fluoride compound (cf. ref. 6). The molar concentration varies but often exceeds that of cytochromes c and b , $d\bar{h}$. The band of the cyanide compound at 538 m μ ⁶ does not, however, appreciably disturb the appearance of the cytochrome c α -band at 550 m μ . Peroxidase is supposed to be reduced in dithionite only. If, however, the intracellular potential of roots during anaerobiosis promotes a reduction of peroxidase, it can be expected that the reduced band at 556 m μ will disturb the cytochrome c α -band at 550 m μ . This question is still unsettled; but reduction of peroxidase may be one of the reasons why in some roots in anaerobiosis the region 540–570 m μ is less transparent than would be expected from the presence of cytochromes only. Another possibility is the presence of a reserve of non-specific haemin which is partly reduced under anaerobical conditions.

The quantity of total haemochromes was determined after treatment of the roots with 10 per cent pyridine and dithionite. The appearance of a high, narrow band at 556 m μ and bands at 526–527 and 425–430 m μ indicates that the overwhelming part of the haemins are protohaemochromes. On fractional extraction with 10⁻³ M sulphuric acid, the haemochromes of cytochrome c appears at 550 m μ . If the concentration of protohaemochrome is calculated from the molar extinction at 556 m μ ($= 3.2 \times 10^4$) the value exceeds that of the enzymes b , $d\bar{h}$ and peroxidase by only c. 15 per cent, as shown by the following average figures from twenty separate experiments:

Cytochrome b	1.43	$\mu\text{mol. l. kgm.}^{-1}$	fresh weight
Cytochrome $d\bar{h}$	1.49	"	"
Peroxidase	1.16	"	"
Total enzymes			
haemochromes	4.08	"	"
Protohaemochrome			
determ.	4.80	"	"

The results show that cytochromes b and $d\bar{h}$ and peroxidase are related to protohaemochrome, but that some protohaemin may be present as a reserve or precursor of the haemin enzymes. There is no indication of haemoglobin-like haemin compounds in the roots (cf. ref. 7). Even if the non-specific haemin reserves are comparatively low in vigorously growing roots, they increase considerably in roots growing under less favourable conditions, a fact pointing to the existence of a pool of haemin more or less shifting over into active enzymes. Most of the non-cytochrome haemin is, however, present as peroxidase.

RADIATION-WIDTHS OF NUCLEAR ENERGY-LEVELS

By PROF. D. J. HUGHES*

Clarendon Laboratory, Oxford

and J. A. HARVEY

Brookhaven Laboratory, New York

THE radiation-widths of levels of low excitation can, if sufficiently narrow ($\sim 10^{-6}$ eV.), be determined directly from the life-time of the state. The vast majority of levels, however, have much greater widths, which are often obtainable from properties of the nuclear reactions in which the levels are excited. The highly excited virtual states lying just above the energy corresponding to the neutron-binding energy have radiation-widths, for A greater than 100, of the order of 0.1 eV. These widths, typically constituting practically the total width of the level, can be measured by observation of the actual shapes of the neutron cross-section resonances that give rise to the excitation-levels. The cross-section resonances usually exhibit the simple one-level Breit-Wigner form, and the full width at half-maximum of the resonance represents the total width, Γ . The detailed shape of the resonance, in particular its peak height, allows the determination of Γ_γ , the radiation-width, by subtraction of the neutron-width, Γ_n , from Γ . The resolution available at the present time with slow-neutron velocity-selectors is sufficient to enable measurement of radiation-widths for many levels of heavy nuclei for excitation energies in the range 6–9 MeV. A survey of the radiation-widths already obtained from slow-neutron resonances reveals some interesting regularities and should be of value in its applications to theories of nuclear structure and in suggesting further measurements.

In Table 1, we present those radiation-widths that have been measured with 'reasonable' accuracy, of the order of 20 per cent. These values are based primarily on the work done in the past few years with pulsed neutron sources (the Columbia cyclotron¹ and the Harwell linear electron accelerator²), the crystal spectrometer at Brookhaven³, and the 'fast choppers' at Argonne⁴ and Brookhaven⁵. The present resolutions of the Harwell accelerator and the Argonne and Brookhaven choppers are about 0.1 μ sec. metre, or 0.09 eV. at a neutron energy of 10 eV. and 2.8 eV. at 100 eV. A resolution of this magnitude allows determination of Γ and $g\Gamma_n$ (with g the statistical weight factor) from the resonance shape up to energies of about 10 eV., and by 'area' methods to about 30 eV. The radiation-width is obtained⁶ from Γ and $g\Gamma_n$ in the general case by an assumption of $g = \frac{1}{2}$; for a zero-spin target nucleus g is known to be unity.

The first noteworthy fact concerning the radiation-widths is the small variation among levels in a single isotope and from isotope to isotope. This constancy is also shown in Fig. 1, which reveals a slight decrease of the radiation-width with increasing A . The excitation energies of the levels the widths of which are given in Fig. 1 range from 6 to 9 MeV., and represent levels in compound nuclei of odd Z -odd N (N , number of neutrons), odd Z -even N , even Z -odd N , and even Z -even N . None of these variables,

however, results in differences in radiation-width larger than the spread represented by the points of Fig. 1, which deviate on the average by only 20 per cent from the solid line. It is known from neutron resonance work not reported here that the spacings of the levels for the isotopes considered vary greatly, yet this difference in spacing apparently is not reflected in a change in radiation-width. An extreme example is furnished⁶ by hafnium-177 with a level-spacing of 8 eV. and hafnium-178 with 100 eV., both having similar radiation-widths.

* Fulbright professor on leave from Brookhaven Laboratory.

Fig. 1. Radiation-widths (Γ_γ) of slow-neutron resonance-levels plotted against atomic weight of the target nucleus. The symbols, $\circ$ odd Z -odd N , $\bullet$ even Z -even N , Δ even Z -odd N , $\square$ odd Z -even N , and $\times$ assignment unknown, refer to the compound nucleus. The errors are shown for the values of Γ_γ that have an accuracy of 20 mV. or better. Almost all the other points have large enough errors to agree with the straight line β .

As the levels studied represent a wide range of angular momenta, J , it is possible to investigate the dependence of Γ_γ on J , the spin of the compound nucleus. In Fig. 2, the measured widths are plotted against the spin of the target nucleus I , with $J = I \pm \frac{1}{2}$. In order to compare nuclei over a large range of A , the measured widths are multiplied by $100/\beta$, where β is the solid line of Fig. 1, in order to remove the slight dependence on A . It is obvious from Fig. 2 that there is little or no dependence of the radiation-width on J , the experimental points, with the exception of the anomalously high value for gold, being consistent with the horizontal line at 100 mV. This finding indicates that the transition probability of an energy-level (almost certainly electric dipole) is independent of J and that no $(2J + 1)$ factor should be included when comparing measured widths with theoretical transition probabilities.

The near-constancy of Γ_γ is of great value in the analysis⁴ of neutron resonances in the region of poor resolution, for example, 20–200 eV. Here the varia-

tion of Γ_γ from level to level is much greater than that of Γ_γ ; hence, in studying the former in the 20–200 eV. region it is safe to use values of Γ_γ obtained at lower energy to obtain Γ_γ from the measurements at poor resolution. The present results on Γ_γ also help to justify the use of a Γ_γ non-dependent on J in the work of Hughes, Garth and Levin⁵, in which level-spacings were obtained from measured capture cross-sections at an effective energy of 1 MeV. In particular, their finding that level-spacings for different J 's are about equal, which depends on the constancy of Γ_γ with J , seems justified.

It is a well-known fact that theoretical estimates of the electric dipole radiation-width of highly excited levels are much larger than experimental

results. For example, Blatt and Weisskopf⁶ calculate widths about 300-fold larger than those of Fig. 1, using the single-particle model. When the radiation-widths are combined with the results of capture γ -studies, which show what fraction of the total radiation-width Γ_γ corresponds to a given transition, it is possible to obtain the partial width for that particular transition. Thus Kinsey and Bartholomew⁷ find by this method that identifiable electric dipole transitions, the relative strengths of which vary greatly, have widths ranging from 0.002 to 0.6 of the single-particle theoretical⁸ value. (We here refer to the measured widths, suppressing the $(2J + 1)$ factor used by Kinsey in his comparison with theory, in line with the present observations.) Unfortunately, not many such cases are available because the measured total radiation-widths are usually for heavier nuclei than those used for capture- γ measurements. For much lighter nuclei⁸ the electric dipole widths of states at high excitation are about 0.1 of the values for single particles⁹.

Thus the radiation-widths so far measured seem to have a remarkable constancy, with the sole exception of a three-fold discrepancy for gold, for different level-spacings, different J 's, and different types of capture- γ decay schemes. It is possible that variations will be found in radiation-widths of isotopes not yet measured, and to this end, those exhibiting the largest differences in the characteristics just mentioned are being actively investigated.

It is a pleasure to acknowledge the help of C. E. Porter, R. C. Garth and Prof. M. H. L. Pryor in the present work, which was supported in part by the U.S. Atomic Energy Commission.

Fig. 2. Radiation-widths of slow-neutron resonance-levels plotted against spin of the target nucleus, with β the "best" straight line of Fig. 1. The symbols are explained in Fig. 1. Errors are shown if less than 25 per cent.

Lunar Radio Echoes and the Faraday Effect in the Ionosphere

SUCCESSFUL observations of the reflexion of radio waves from the moon have been made by workers in the United States and Australia. Both DeWitt and Stodola¹ and Kerr and Shain² found that the lunar echoes showed rapid fading (periods of seconds), for which the most likely cause appeared to be the libration of the moon. They also noted a different type of fading of much longer period for which no satisfactory explanation has been found, although Kerr and Shain obtained evidence that it might have an ionospheric origin. A radio echo equipment at the Jodrell Bank Experimental Station has recently been used in an investigation of the fading of lunar echoes; the results are in general agreement with this previous work as regards the origin of the short-period fading. The purpose of the present communication is to offer an interpretation of the long-period fading.

The equipment worked at a frequency of 120 Mc./sec. and the aerial system of 250 sq. m. aperture was arranged so that the moon could be observed for forty-five minutes at lunar transit. During thirty observing periods in the lunations of October and November 1953, 50,000 echoes were photographed and analysed. The night-time runs showed a steady r.m.s. signal amplitude (see Fig. 1a) while the day-time runs, particularly those within a few hours of sunrise, were characterized by severe fading (see Fig. 1b). The only runs which were exceptional were two night-time observations during which the fading occurred; on one of these nights there was also severe disturbance to trans-Atlantic short-wave communication, and on the other there was auroral activity. This general evidence therefore strongly suggests an ionospheric origin.

Kerr and Shain² showed that the movement of irregularities in the ionosphere might give rise to the fading. The speed of movement of these irregularities (300 m./sec. in the *F*-region, 50 m./sec. in the *E*-region) is, however, far too great to account for the fading periods of up to an hour observed in the present series of experiments. It is suggested that the long-period fading is due to the rotation of the plane of polarization of the radio waves as they traverse the ionosphere in the presence of the earth's magnetic field. Since the receiving aerial is plane-polarized, any slow rotation of the plane of polarization of the returned signals, as the electron content of the ionosphere varies, would give rise to changes in amplitude of the observed echoes. It can be shown from the Appleton-Hartree magneto-ionic theory that, for frequencies above 100 Mc./sec. and for restricted inclinations θ of the geomagnetic vector to the line of sight, the total polarization shift Ω for the double passage through the ionosphere is given approximately by

$$\Omega = \frac{7,490 H \cos \theta}{f} \int N dr \text{ complete rotations,} \quad (1)$$

where f is the transmitted frequency in c./s., H the geomagnetic field in e.m.u., $N(r)$ the electron number density per c.c. and dr cm. the element of path length

along the line of sight between the aerial and the moon where the electron density is N . Substitution in (1) indicates that the change in Ω necessary to give maximum to minimum fading would require a change in mean electron density of about 5×10^4 electrons/c.c. over a path length of 200 km. Such a change is observed in a period of 30–60 min. during early morning runs; its rate is consistent with the rate of change of electron density in the *F*-region associated with the transition from night-time to day-time conditions.

Experiments to confirm the effect have been carried out using the 250 sq. m. aperture horizontally polarized aerial for transmission and a separate aerial of 30 sq. m. aperture for reception; the latter was a paraboloid with a primary feed consisting of two dipole units mounted at right angles. The receiver was switched between the vertical and horizontal feeds at minute intervals. In five afternoon and evening observations during the lunation of March 1954 echoes were received in both planes of polarization, their relative r.m.s. amplitudes in the two planes varying differentially from day to day and also during the period of each run. For example, in a 45-min.

Fig. 1 a, Amplitude of lunar echoes during night-time observation on November 17, 1953. Lunar transit was at 2100 U.T.; b, amplitude record of lunar echoes during daytime observation on October 3, 1953, transit at 0840 U.T. Ordinates are amplitude signal/noise ratios (r.m.s. of 34 echoes in one-minute periods) corrected for the moon's position in the aerial beam

observing period commencing at 1650 U.T. on March 10, the amplitudes of the echoes in the two polarizations were equally divided at the start; shortly after transit at 1713 U.T., echoes were received only in the vertical plane; towards the end of the observing period echoes again became distinguishable in horizontal polarization. Such results confirm that the long-period fading is caused, at least in part, by a change of polarization in the received lunar echo.

In equation (1) $\int N \cdot dr$ is the total electron content of the ionosphere per sq. centimetre along the line of sight; the lunar echo technique thus affords a method for determining this quantity directly. The present experiments give only the rate of change of $\int N \cdot dr$. Measurements at two close-spaced frequencies would be required to determine the total rotation and hence the total electron content of the ionosphere.

We wish to thank Dr. I. C. Browne, Dr. T. R. Kaiser and Prof. A. C. B. Lovell, director of the Station, for their assistance in this work. One of us (W. A. S. M.) was the recipient of a maintenance grant from the Department of Scientific and Industrial Research during 1950-53.

Galactic Radio Sources of Large Angular Diameter

THE survey of extra-terrestrial radiation, made at 1.89 m. with the 218-ft. paraboloid at Jodrell Bank, gave the position and intensity of 23 localized sources¹ between declinations N. 38° and N. 68°. The distribution of the intense sources showed a marked concentration close to the galactic plane, and it was concluded that they represented a class of rare objects in the Galaxy. A similar concentration has been found by Mills² from observations in the southern hemisphere. An attempt has now been made to measure the apparent angular width of these sources, and the present communication gives the preliminary results.

The measurements have been made at 1.89 m. using the 218-ft. paraboloid as an interferometer in conjunction with a small mobile aerial of 35 sq. m. aperture. The small aerial was placed at various distances along an east-west base-line from the fixed paraboloid, and in each position the amplitude of the interference pattern in the receiver output was recorded as the sources were in transit. The apparent angular size of each source was found from the change in the amplitude of the pattern with aerial spacing by using the well-known relation³ between the amplitude and the distribution of intensity across the source. The effects of systematic errors and long-period changes in the calibration of the equipment were minimized by daily observation of the transit of the intense source in Cassiopeia (No. 23) for which the intensity¹ and angular diameter is already known^{4,5}.

Table 1

Reference No. ¹	Galactic longitude (deg.)	Galactic latitude (deg.)	Intensity* at 1.89 m. (watt. m. ⁻² (c/s.) ⁻¹ × 10 ⁻²⁶)	Apparent angular width	Remarks
1	87.5	+2.1	170	—	Not measured
3	100.5	+2.1	80	>1.5° <3°	
7	111.8	-0.8	60	>1.5° <3°	
8	121.	-1.5	50	>1.5° <3°	
9	123.8	+3.8	80	1.4° ± 0.4°	Identified with nebula in Fig. 2
19	43.6	+4.9	5,700	2' 10" × 35" (ref. 6)	Identified as extra-galactic (ref. 10) Cygnus X
20	45.9	+0.8	300	1° or 5" (ref. 9)	
21	56.5	+4.1	200	1.5° ± 0.4°	
22	66.4	+2.9	50	—	Not measured
23	79.6	-2.0	9,350	5' × 4' (refs. 4, 5, 6)	Cassiopeia I

* The intensity given is the maximum intensity observed in a 2° beam. It has not been corrected for the finite size of the source.

The original survey¹ listed ten sources within ± 5° of the galactic plane, as shown in Table 1, all of which were classified as intense (> 50 × 10⁻²⁶ watt. m.⁻² (c/s.)⁻¹). The present observations have been restricted to five of these sources (Nos. 3, 7, 8, 9 and 21) and the measured values of their angular sizes are shown in Table 1. The angular sizes of sources 19, 20 and 23 have been quoted from previous observations⁴⁻⁶. Measurements could not be carried out on Nos. 1 and 22, since serious interference was experienced in their positions from the reception of nearby intense sources in side-lobes of the aerial system.

The variation in the amplitude of the interference pattern observed at different aerial spacings for source 9 is shown in Fig. 1. The results for source 21 were almost identical. In both cases the width of the equivalent strip source is about 1½ deg. Sources 3, 7 and 8 were found to be even greater in size and it was only possible to assign an approximate lower limit of about 1½-2 deg. to their equivalent widths, since the minimum spacing between the two aerials was restricted to about 20 λ by the size of the fixed paraboloid. An upper limit to the size of these three sources of about 3 deg. has been established by inspection of the records obtained in the original survey¹.

An examination of the sky in the position of source 9 has been made by Minkowski⁷ using plates

Fig. 1. The relative amplitude of the interference pattern observed from source 9. The value given for zero base-line is derived from the original survey (see ref. 1).

Fig. 2. A faint nebula in Auriga. The broken line shows the outline of the nebula. The position, and associated errors, of the radio source are given by the rectangle. The positions of α -Auriga and B.D. 46° 9' 49\"/>

taken during the National Geographic Survey with the 48-in. Schmidt telescope of the Mount Wilson and Palomar Observatories. He has found that in the approximate position of the source there is a faint nebula the outline of which is sketched in Fig. 2. The sketch has been made from an exposure taken in red light; only faint traces of the object can be seen in the blue. The nebula contains some faint filaments which are most prominent at the western edge. The co-ordinates of the radio source agree closely with the centre of the nebula, and the width of the equivalent source (1.4 ± 0.4 deg.) is comparable with the extension of the nebula in an east-west direction (~ 2 deg.). In view of this agreement, source 9 may be provisionally identified with the nebula.

In addition to the sources listed in Table 1 three other intense sources with large angular diameters have been reported close to the galactic plane in regions outside the field of view of the present equipment. Thus Mills⁸ has observed two intense sources with angular diameters greater than half a degree at $l = 229^\circ$, $b = 0^\circ$ and $l = 330^\circ$, $b = 4^\circ$. Bolton¹¹ has reported that the former of these two sources, in Puppis, has an angular diameter of about 1° . More recently, Baldwin and Dewhurst⁹ have observed a source in Gemini with an angular width of about one degree associated with the nebula I.C.443. Bolton¹¹ has also reported the presence of extended patches of radiation in the galactic plane, nearer to the galactic centre, which may result from the presence of several of these extended sources.

Thus, by combining the data in Table 1 with observations made in other parts of the sky, a total of at least nine intense sources with diameters of the order of a degree have been found close to the galactic plane; furthermore, at wave-lengths of about two or three metres, the apparent surface temperatures of these sources are all of the order of a few hundred degrees K. The similarity between these sources is striking and suggests that they represent a definite class of object in the Galaxy.

At the present time, only five objects in the Galaxy have been identified with radio sources. These are the Crab Nebula in Taurus¹², the nebulosities in Cassiopeia^{10,13}, Puppis¹¹ and Gemini⁹ (I.C.443) and the nebula in Auriga shown in Fig. 2. The radio sources associated with the Crab Nebula and with the nebula in Cassiopeia (source 23) appear superficially to be different in character from each

other and from the remaining three. They have angular diameters of a few minutes of arc and their apparent surface temperatures are of the order of thousands and millions of degrees respectively. The remaining three radio sources, which have been included among the nine sources already discussed, appear to be similar. Their associated nebulosities all show the presence of filaments but do not resemble each other exactly; nevertheless, the association of these three sources with nebulosities, together with their similarity to the other six unidentified sources of large diameter, indicate that the origin of this class of intense radio source is to be found in extended nebulosities of low photographic brightness.

We wish to thank Prof. A. C. B. Lovell and Prof. Z. Kopal for their interest in the investigation. We also wish to thank Dr. R. Minkowski for his generous co-operation. One of us (A. R. T.) is indebted to the Department of Scientific and Industrial Research for a maintenance grant.

Proton Polarization at ~ 130 MeV.

RECENT theoretical investigations¹ of high-energy nucleon-nucleon scattering have involved the use of non-central forces in the description of the interactions between nucleons and consequently have predicted neutron and proton polarization. Experimental evidence for proton polarization was first obtained by Oxley *et al.*² at 240 MeV., and preliminary results from Harwell at 133 MeV., Chicago at 337 MeV. and Berkeley at 300 MeV. were reported at the Rochester nuclear physics conference³. Neutron polarization effects are much smaller than proton polarization effects under all the experimental conditions investigated to date³.

Nucleon polarization is detected in a double-scattering experiment. If the angle between the normals to the two scattering planes is φ and the angles of the first and second scatterings are θ_1 and θ_2 , then it may be shown that the asymmetry, ϵ , in the beam intensities $I(\varphi)$ after the second scattering is

$$\epsilon = \frac{I(0^\circ) - I(180^\circ)}{I(0^\circ) + I(180^\circ)} = P_1(\theta_1) P_2(\theta_2),$$

where $P(\theta)$ is the fractional polarization produced by a single scattering.

In the present experiment the internal (presumably unpolarized) proton beam of the Harwell cyclotron was scattered through 20° by a 10-MeV. thick copper or carbon target and was extracted from the machine by the aid of a magnetic deflector channel in an arrangement suggested by J. M. Cassels. The proton energy selected by this channel was 133 MeV., while the effective primary beam, taking into account multiple traversal effects, covered a range of 143–166 MeV. The polarized proton beam from the carbon first target had a flux of 3×10^8 protons/sec./cm.² at the second target, which was located behind a 6-ft. thick shielding wall and at a distance of 25 ft. from the first target. The beam from the copper target was 10^8 protons/sec./cm.². The protons scattered from the second target were counted in a triple-coincidence scintillation counter telescope with an azimuthal acceptance angle of 8° . When polyethylene was used as a hydrogen second target, the recoil protons were counted in coincidence with the scattered protons. The telescope could be moved in the plane of the scattering to vary θ_2 , and the framework on which it was mounted could be rotated about the axis of the beam to vary ϕ .

We shall use the notation (X, Y, θ_2) to denote that the first and second targets were of materials X and Y respectively and that the angle of the second scattering was θ_2 .

For conditions $(C, C, 20^\circ)$, $(C, C, 30^\circ)$ and $(C, U, 20^\circ)$, the asymmetry, ϵ , increased as the threshold energy, E_T , for proton detection by the counter telescope was raised (Fig. 1), while for $(C, H, 20^\circ)$ ϵ was, of course, independent of E_T and was equal to 0.14 ± 0.02 . For $(C, C, 45^\circ)$ and $(C, U, 45^\circ)$ ϵ was small (not statistically different from zero) for $E_T = 45$ and 112 MeV. The largest values of ϵ were found to be associated with a high-energy group of elastically or near-elastically scattered protons. In Fig. 2 are drawn the proton-energy spectra deduced from the

Fig. 1

Fig. 2

absorption curves of $(C, C, 20^\circ)$, showing a very strong peak at the full energy corresponding to elastic scattering of the protons; the 'elastic' peak was much smaller for $(C, C, 30^\circ)$ (consistent with the first diffraction minimum near 30°), but it was well defined for $(C, U, 20^\circ)$. The asymmetry of 0.8 for $(C, C, 20^\circ)$ implies that P_1 and P_2 ('elastic') are both greater than 0.8. Now, making the assumption that there is no appreciable variation with energy between 133 MeV. and 143–166 MeV., P_1 must be less than P_2 , since the first scattering was not all elastic scattering; consequently, $0.6 < P_1 < 0.8$ and $0.8 < P_2$ ('elastic') < 1.0 . The asymmetry for inelastic scattering was much smaller than for elastic scattering. A diffuse group of protons was apparent for $(C, C, 20^\circ)$ with energies approximating to the free p - p scattering energy, and for this group $\epsilon = (0.27 \pm 0.05)$. No groups could be distinguished for $(C, C, 30^\circ)$ or $(C, U, 20^\circ)$, but in the appropriate energy-ranges ϵ was (0.15 ± 0.05) and (0.05 ± 0.03) . Below 70 MeV. the scattered protons showed no significant asymmetry.

In a similar beryllium-beryllium asymmetry measurement at Chicago at 337 MeV., ϵ was found to increase with E_T in such a manner that it was concluded that all the polarization effects were due to elastic scattering. At Berkeley the results of $(C, C, 15^\circ)$ measurements were interpreted as showing that both elastic and inelastic scattering produce asymmetry. There is therefore some uncertainty as to whether or not all the polarization is due to elastic scattering at about 300 MeV., whereas our results unambiguously show quite a pronounced asymmetry for the inelastic events.

The angular distribution (15° – 45° lab.) of the (C, H, θ_2) asymmetry is shown in the table. If the beam polarization, P_1 , is (0.7 ± 0.1) the free proton-proton polarization, $P(H)$, is (0.20 ± 0.05) at 20° . The value of $P(H)$ obtained by Oxley *et al.* at 200 MeV. was (0.22 ± 0.04) ($\theta_1 = 19^\circ$, $\theta_2 = 27^\circ$). Measurements at Berkeley of $(C, H, 20^\circ)$ and at Chicago of $(Be, H, 20^\circ)$ reported at Rochester² both gave $\epsilon = 0.2$, and from other measurements P_1 was at least 0.5, so that at 300 MeV. $0.2 < P(H) < 0.4$. There are therefore no large differences between the p - p polarizations at 130, 200 and 300 MeV. The

shape, of the angular distributions measured at Berkeley and Chicago were both substantially the same as the present measurements, but showed in addition that $P(H)$ was nearly constant from 20° to 5° . This is to be compared with the theoretically predicted $\sin\theta \cos\theta$ variation.

θ (lab.)	15°	$17\frac{1}{2}^\circ$	20°	25°
s	0.19 ± 0.03	0.19 ± 0.025	0.14 ± 0.03	0.11 ± 0.015
θ (lab.)	30°	35°	40°	45°
s	0.11 ± 0.03	0.07 ± 0.02	0.045 ± 0.03	-0.01 ± 0.015

The most direct interpretation of our measurements is that elastic scattering from carbon yields protons at 20° and 30° which are very highly polarized (> 80 per cent and > 60 per cent, respectively); these values are roughly four times the free p - p polarization at these angles. Similarly, elastic scattering from uranium at 20° gives a polarization approximately twice the free p - p polarization at that angle. Inelastic events also may yield polarizations higher than that in p - p scattering. The sign of the polarization effects has not been determined, but it is the same for nuclear and p - p polarizations.

This work on proton polarization effects is continuing and a fuller report will be issued later. We wish to thank Dr. T. C. Griffith for his collaboration in some of these experiments, and Dr. T. G. Pickavance and Mr. B. Rose for their continued encouragement and advice.

Errors in Particle-size Determination from Settled Suspensions

THE particle-size distribution of finely divided materials is sometimes obtained by sizing settled suspensions under the microscope. This distribution is then assumed to represent that of particles orientated at random. In recent experiments on the extinction of light by silica dust suspended in liquid the cross-sectional area obtained microscopically seemed too large. Since the suspended particles were fairly uniform in size, it seemed improbable that the discrepancies arose from sizing errors, and more likely that the particles of extreme shape tended to settle flat on the slide.

In order to obtain samples which had not been orientated in this way, the particles were suspended in carefully filtered agar solution, and the suspension for sizing poured on to a microscope slide under conditions such that it set within a few seconds. In this way the orientation of the suspended particles was 'frozen in'. Hydrodynamic effects may orientate the particles in the agar before it sets, but they are unlikely to give rise to the same errors in sizing as does the orientation of the settled suspension.

The particles were then sized by microscope, using a Patterson-Cawood graticule, and classified

Table 1

Size range, microns	Mean area per particle (microns ²) and number sized (in brackets)		Significance level, difference between distributions: χ^2 test	
	Settled	Suspended in agar		
8-30	350 (960)	322 (373)	$P < 0.1$	5 D.F.
4-20	115.7 (663)	96.7 (452)	$P < 0.001$	5 D.F.
2.4-7.5	29.0 (400)	23.0 (343)	$P < 0.001$	4 D.F.
1.2-4	4.88 (390)	3.67 (153)	$P < 0.02$	6 D.F.

according to their projected areas. The technique employed was that used in the sizing of settled particles, except that the microscope was racked up and down to focus through the depth of the agar film. The size distributions obtained by the two methods were compared by means of the χ^2 test. Some of the original seven or eight size-groups had to be combined owing to the small numbers of particles in the larger groups.

Four different suspensions were studied (see Table 1). In each case the upper size-limit quoted embraced more than 90 per cent of the particles sized; most particles lay within considerably narrower ranges. There seems little doubt that the distributions are different, and can give rise to considerable differences in mean area per particle. The mean areas are, however, subject to considerable statistical errors owing to the small numbers of particles sized.

It is possible that similar differences in distribution might be obtained from apparently identical preparations. Three pairs of such identical preparations were therefore compared by the same technique; but no significant differences were found. The differences between settled and 'frozen-in' suspensions appear, therefore, to be real. The cross-sectional areas obtained by the latter method gave good agreement with those indicated by the light-extinction.

For particles smaller than about 1 micron diameter, the method becomes very difficult to use. Objectives of high magnification, short focus and small depth of focus must be used, and the volume in focus at any one time is small. Moreover, Brownian movement becomes more important and orientation seems less likely to persist.

I am grateful to Mr. M. J. Robbins, of the Department of Bacteriology, London School of Hygiene and Tropical Medicine, for preparing artefact-free agar solution.

Variation of Hardness of Metals with Grain Size

In the past, several sets of measurements have been made of the variation of Brinell hardness number with grain size, notably on α -brass¹, copper and bronze², and 'Armco' iron³. The consistent increase of hardness with grain size was interpreted by these workers^{1,2} as being dependent on the amount of grain boundary area; that is, a plot of the hardness number against $1/d$, where d is the grain diameter, gave a straight line. However, I have found that a

Fig. 1

plot of hardness number against $1/d^{1/2}$ gave equally 'good' straight lines, since the scatter in the original results was rather high, and in one case (α -brass) an even better fit was obtained (Fig. 1).

An interpretation of the results then appears possible, following the treatment of the variation of the lower yield stress in mild steel with grain size, which obeys a similar law⁴. When an indentation is made in a metal surface, the size of the indentation can only increase by plastic yielding in the surrounding grains. The transmission of deformation from one grain to another can be pictured on the following model: assume dislocations to pile up against a grain boundary, then the stress σ at a distance x ahead of the dislocation nearest to the grain boundary is given by

$$\frac{\sigma}{\sigma_0} \approx \left(\frac{L}{x}\right)^{1/2},$$

where σ_0 is the applied stress, and L is the length of the glide plane⁵. The adjacent grain will yield when σ reaches a certain critical value, and, identifying L with the mean grain diameter d , we find

$$\sigma_0 \propto \frac{1}{d^{1/2}}.$$

Thus all grains supporting a stress equal to or greater than σ_0 will have yielded, and assuming the extent of the plastically deformed zone is proportional to the size of the impression, the hardness will vary as $1/d^{1/2}$.

Alternatively, this analysis shows that the (local) yield stress varies with the grain size, and since Tabor⁶ has shown that the Brinell hardness is proportional to the yield stress, the same result follows.

Inhibition of Glucose Use in Muscle Extracts by Lipoproteins

FOLLOWING the demonstration that the serum of severely diabetic rats inhibited the uptake of glucose by the rat diaphragm¹ and the later finding that such inhibition was dependent on the lipoprotein content of the serum², it was decided to test the effect of lipoprotein fractions obtained from diabetic plasma, the anterior pituitary and other tissues on the utilization of glucose by cell-free muscle extracts.

The lipoproteins used have been obtained either by alcohol fractionation of plasma³ or by flotation in the ultracentrifuge at an appropriate specific gravity, the lipoprotein being removed and precipitated with zinc for purposes of storage. In the earlier experiments the lipoproteins were dissolved and then dialysed against several changes of saline; but as the possibility had to be considered that zinc ions may be inhibiting some enzymes in the system⁴, in the more recent series reported here (Table 1) versene (ethylenediaminetetraacetic acid) has been used to bind the cation, or else zinc has been removed by passage through an appropriate ion-exchange resin prior to dialysis. All extracts were tested for zinc content with dimethylthiocarbazon, and under the experimental conditions used the maximum concentration of zinc in the system was less than 1×10^{-7} M.

The effect of such fractions has been tested on a standard system consisting of: glucose, 1.2 micromoles; muscle extract, 0.2 ml. (1 gm. muscle extracted with 1 ml. saline and adjusted to pH 7.45); phosphate buffer (pH 7.45), 10 micromoles; adenosine triphosphate, 5 micromoles; Mg^{++} , 5 micromoles, the appropriate amount of lipoprotein solution and water to a total volume of 0.7 ml. The system was incubated for 15 min. at 37°C. and glucose determined after deproteinization.

The glucose utilized has been calculated by difference between experimental results and incubated systems containing no adenosine triphosphate. The results obtained are shown in Tables 1 and 2. As the fraction obtained by alcohol fractionation of plasma is contaminated by other proteins, the quantity used is expressed as ml. of original plasma.

In addition to the experiments shown in the tables a large number of other experiments have been made with minor variations in technique. In all cases inhibition of the system by lipoprotein has been demonstrable, although with plasma lipoproteins the amount required to produce inhibition varies considerably from sample to sample. One of the most marked features has been the minute quantity of anterior pituitary lipoprotein which has produced well-marked inhibition, as little as 3 μ gm.

being effective on a number of occasions. However, pending the demonstration of hormonal activity in such preparations, it would be premature to draw conclusions as to the physiological role of lipoprotein fractions in the control of carbohydrate metabolism.

In view of the proposal that insulin may influence glucose utilization directly¹, the effect of insulin upon the lipoprotein inhibition was explored; the insulin, where present, was 0.1 unit per ml. Most irregular results were obtained, as recorded in Tables 1 and 2. The irregularity is best shown in Table 1, where in Exp. 4 the same materials were used at 4-hr. intervals and the second test showed an apparent insulin effect but the first did not; again, in Exp. 7, with three tests done simultaneously, an insulin effect was obtained in one, but not in the other two. Altogether, in forty-two experiments done recently, a reversal of the inhibition by insulin was observed in twelve. Other proteins were tested in place of insulin, namely, insulin inactivated by alkali, glucagon, hyaluronidase, and serum albumin; in no instance was reversal of lipoprotein inhibition observed. However, in view of the irregularity of insulin effects, it is not possible to state whether this is of significance in a small series. For the same reason, no conclusions can be drawn at present as to whether such a mechanism is concerned with the physiological action of insulin.

In summary, lipoproteins from plasma, anterior pituitary, liver, and muscle have been found to inhibit glucose utilization by muscle extracts. Insulin reversal of this inhibition has been observed in a limited number of experiments.

This work, which was initiated by the authors in the Department of Biological Chemistry, Washington University, St. Louis, is being continued, and full details will be published elsewhere.

Fibrogenesis in Connective Tissues

WHILE it is now generally accepted that the cell plays a dominant part in the fibrogenesis in connective tissues, the mechanism of the formation of the fibrils of collagen and those of elastic tissue and cartilage is completely unknown. The object of this communication is to direct attention to the presence of sub-microscopical filaments in the cytoplasm of fibroblasts, osteoblasts, osteocytes and chondroblasts. The present observations were made with the electron microscope and using ultra-thin sections of tissue.

Sections of normal thickness for study in the light microscope and the much thinner sections for the electron microscope were each prepared from the middle segment of the metatarsal rudiment of embryonic fowls of age 4-15 days, and from the mandible of 7-12-day embryos. All specimens were fixed in 1 per cent osmium tetroxide at pH 7.4¹ and embedded in ester wax over *n*-butyl alcohol and chloroform. The specimens for electron microscopy were mounted on a standard coated grid and viewed in a Metropolitan-Vickers electron microscope Type EM3 at 75 kV., a 30- μ or 60- μ objective aperture being used.

The control sections show that at about the sixth day of incubation the cells which surround the cartilaginous shafts of the metatarsus differentiate into an outer fibroblastic and an inner osteoblastic layer. In electron micrographs of transverse sections of this central hypertrophic region, the cytoplasm of the osteoblasts is seen to be packed with long fine filaments about 120 Å. in diameter, some of which enlarge to about 500 Å. in diameter in later development (Fig. 1). The filaments often lie in pairs, and each appears to be joined to its neighbour by short junctions at intervals of about 700 Å., while others seem to be twisted together into a complex helix. These single and composite filaments are usually parallel to each other and are separated by distances of 200-1000 Å.; they are also associated with mitochondria and in some cells seem to be woven around the latter.

As the age of the fowl embryo increases, the innermost layer of osteoblasts becomes sharply defined from the adjacent cartilage by a narrow dense strip which indicates the first stage of ossification. Where the cytoplasm of the osteoblasts is in immediate contact with this periosteal bone, no dividing line between the developing matrix and intracytoplasmic filaments can be distinguished; it appears that the filaments become part of the bone matrix. At present the mechanism whereby the organic matrix is laid down is not understood, as round electron-dense particles which may be related to the deposition of mineral salts are scattered throughout the region, and this quickly renders the bone matrix opaque to the electron beam.

Similar, though fewer, intracytoplasmic filaments have been observed in osteocytes of the periosteal bone, in osteoblasts and osteocytes of endochondral and membrane bone, in fibroblasts of the perichondrium and of tendon sheaths, and in chondroblasts of the hypertrophic cartilage in long bones and in the ossifying articular region of Meckel's cartilage. In the last, only single, long, well-separated filaments have so far been recorded; the other types of fibrogenic cells contain mainly short filaments and particles, and only a few contain long orientated filaments. The appearance of the micrograph, even in a cell

Fig. 1. Electron micrograph of a section through the osteoblastic layer of the periosteum which lies adjacent to the developing periosteal bone in the metatarsus of an 11-day fowl embryo. The cytoplasmic regions are packed with filaments, while electron-dense particles can be seen in the osseous sheath visible in the upper part of the photograph. $\times 14,000$

with well-aligned filaments, varies according to the plane of section with respect to the orientation of the filaments, and the orientation itself varies from cell to cell.

It is striking that in transverse sections of the metatarsus, that is, in sections cut at right angles to the long axis of the bone rudiment, the osteoblasts of the periosteum display long intracytoplasmic filaments which are parallel to one another and lie precisely in the plane of the section. It is possible that this orientation has been brought about by subjection of the tissue to tension during growth, for the layer of osteoblasts may be compressed between the outer fibrous coat of the periosteum and the expanding cartilage of the shaft¹. Longitudinal sections cut tangentially through the osteoblastic layer show similar precisely aligned filaments. But in longitudinal sections cut through the long axis of the shaft intracytoplasmic filaments are not observed in the osteoblasts; instead, the cytoplasm shows granules with no precise orientation which may well represent the filaments in cross-section. These observations indicate that the long axis of the filaments in the cytoplasm lies at right-angles to the length of the bone rudiment and that the filaments are arranged in layers within the osteoblasts of the periosteum.

The use of thin sectioning techniques during the past few years has added much to our knowledge of cytoplasmic content and submicroscopical structure². The observations have been interpreted in various instances to indicate the presence of lamellae, tubules and double membranes. Such structures appear to be associated particularly with the basophilic regions of protein secretory cells. Careful examination of hundreds of micrographs strongly indicates that the cytoplasm of all the fibrogenic cells which have so far been investigated contains filamentous bodies; the observations are not at present consistent with the presence of membranes or tubules. There is thus no obvious reason at this stage for relating the cytoplasmic structures of the

cells concerned in collagen formation with the intracellular structures occurring in secretory cells of the perenchyma.

The presence of intracellular cytoplasmic filaments in fibrogenic cells does not in itself establish that such structures play a direct part in fibrogenesis. The absence of any visible demarcation between the osteoblasts and the periosteal bone (Fig. 1), and the close resemblance of the cytoplasmic filaments and the intercellular fibrils of the bone matrix, suggest that the filaments may become extracellular. Further work in progress will show whether this hypothesis is correct. An attempt is also being made to determine the chemical nature of the intracellular filaments. This also should have an important bearing on the mechanism of fibrogenesis in connective and skeletal tissues.

I am indebted to Dr. H. B. Fell, Prof. J. T. Randall and Dr. W. Jacobson for their continued advice and encouragement.

Phase-Contrast Microscopy of the Gomori Reaction for Alkaline Phosphatase

In the standard Gomori technique for the histochemical demonstration of alkaline phosphatase, calcium phosphate deposits are formed in sections supposedly at sites of enzyme activity. These deposits, thought to be invisible, must be brought to light by a further procedure. Calcium may be converted to cobalt and the latter visualized as the black sulphide; the von Kossa silver technique may be employed; or lake-forming dyes may be used for colouring the deposits.

We have carried out experiments using paraffin sections of alcohol-fixed duodenum from young rats. Following incubation in substrate¹ in the usual way, we have rinsed the slides in distilled water buffered at pH 9.20 with sodium barbital, dehydrated, and mounted them direct in Canada balsam without any further treatment. We have studied their appearance with the phase-contrast microscope and have observed progressive changes in the appearance and optical properties of the sections as incubation proceeds. The changes do not take place in sections incubated in a substrate bath lacking phosphate ester or in sections heated to destroy intrinsic enzyme prior to incubation.

Control sections were dewaxed, taken to buffered water for 2 min., dehydrated and mounted. Compared with these, after 1-min. incubation the brush

(1) 1-min. incubation. The epithelial free border appears dark (phase positive) and striations may be distinguished. (2) 2-min. incubation. Striation is no longer visible. Two phase-negative areas are present in the border, separated by a phase-positive zone. To the right, the border is almost invisible. (3) 4-min. incubation. The border is now continuously phase negative. In the upper portion it contains minute 'pre-crystals' while, in the lower part, larger (black) crystals are to be seen slightly out of focus. (4) 16-min. incubation. The border is filled by a shining, solid mass of crystals.

Phase-contrast photographs. $\times 750$

border of the cells appears slightly darker and more clearly striated (Fig. 1). After 2 min. the optical properties of the border are affected in a patchy manner. In some places it remains darker than the background (that is, phase positive); in others, it becomes invisible; while elsewhere, transmitting more light than the background, it becomes markedly phase negative (Fig. 2). Minute phase-negative crystal-like structures ('pre-crystals') can just be resolved within such areas; but striation is no longer visible. After 4 min. the border is continuously phase negative and, in addition to 'pre-crystals', quite large, shining crystals appear (Fig. 3). These increase rapidly with time until after 16 min. they form an almost solid mass which fills the border completely (Fig. 4).

If the coverslip is removed from such a section and the slide is remounted in bergamot oil instead of Canada balsam, the phase-changes and 'pre-crystals' can no longer be seen. The border appears dark, without 'pre-crystals'; the crystals also are more difficult to define. If the section is once again mounted in balsam, it reverts to its original appearance. Bergamot oil has a lower index of refraction than Canada balsam. This suggests that the reversal of phase behaviour is due, not to a simple loss of substance from the section during incubation, but to alterations in the refractive index of its different parts resulting from the superimposing of some material thereon during incubation. The phase-changes, the 'pre-crystals' and crystals are all abolished by brief immersion in dilute mineral acids; moreover, gypsum crystals can be seen to form over the border when a drop of melted glycerine jelly acidified with sulphuric acid is added. These facts suggest that, as might be expected, the material deposited and responsible for the phase-changes and crystal formation is in fact calcium phosphate.

We are studying the effects of longer incubation periods, the behaviour of other tissues and freeze-dried material, with the object of comparing the

localization of sites of enzyme activity indicated by this new method with the classical techniques.

Silk-Phosphoric Acid Solutions

NATURAL silk is readily soluble in several solvents, such as cupriethylenediamine, lithium bromide and lithium rhodanide, phosphoric acid, etc. Generally, it is assumed that the dissolution is brought about in such a way that the solvent splits the hydrogen-bonds which intermolecularly connect adjacent fibroin chains, attaches itself to the positions now made available and thus transforms the fibroin into a hydrophilic, water-soluble modification. Schauenstein¹ stated that this procedure could be followed by means of ultra-violet spectroscopy by virtue of the 'peptenol' chromophore, the intensity of which should be a measure of the intermolecular hydrogen-bonding, and which shows a distinct and specific absorption in the region of about 250 m μ . In the course of regeneration experiments with phosphoric acid solutions, different silk samples were investigated in a Beckman spectrophotometer, namely, natural silk, silk dissolved in phosphoric acid (diluted with water), the aqueous silk solution obtained by dialysing the phosphoric acid solution and, finally, films prepared by drying the aqueous solution. The absorption curves obtained are shown in Fig. 1. In view of the above considerations, this result would mean that natural silk contains by far the largest amount of intermolecular bonds, whereas the phosphoric acid solution has lost most of them. Yet the aqueous solution shows an increase in the hydrogen-bonding, and still more so does the film, although without reaching the high value of natural silk.

Independently of this problem, the question arises whether all the solvents mentioned cause decomposition of the silk molecule or not. Howitt² claimed that

Fig. 1. Ultra-violet spectrograms of silk samples: (1) natural silk; (2) silk film prepared from aqueous solution; (3) aqueous silk solution; (4) phosphoric acid-silk solution.

cupriethylenediamine does not do so; but Signer³ has recently doubted that statement. Lithium bromide⁴ and lithium thiocyanate⁵ seem to maintain the original molecular weight. We have examined the phosphoric acid solutions by means of viscosity measurements extending over a period of 30 hr. It was found that a noticeable decrease of intrinsic viscosity takes place, as shown in the table.

Time	$[\eta]$
10 min.	1.13
5 hr.	0.82
25 hr.	0.54

This decrease in viscosity may be caused by either a molecular rearrangement (folding of chains) or by an actual decomposition of the silk molecule; or by both these effects. Although a decision based on these results is not possible, to us the second explanation (decomposition) seems the more probable one. It might also explain the numerous difficulties encountered when trying to spin useful fibres from phosphoric acid solutions⁶.

Finally, one further observation should be mentioned. If the process of dissolving silk in phosphoric acid is observed under the microscope, it is seen that the acid first attacks the fibre at regularly spaced positions, thus after a few seconds creating the impression of a dotted line (with segments of about 100 μ m length). A few minutes later complete dissolution is achieved.

Synthesis of Oligosaccharides during Enzymatic Hydrolysis of Cellobiose by *Aspergillus flavus*

DURING our investigations on the synthesis of oligosaccharides from simple sugars by various mould extracts it was found that the mycelial extract of *Aspergillus flavus* was capable of synthesizing oligosaccharides from cellobiose. The dialysed extracts of the mould converted cellobiose into glucose and four other saccharides, three of which occupy positions below cellobiose and one between cellobiose and glucose on the paper chromatogram. Similar observations were reported recently by Crook and Stone¹ by the action of *Aspergillus niger* on cellobiose. The substances were not identified. Barker *et al.*² have recently reported the synthesis by *Aspergillus niger* (strain 152) of some oligosaccharides which were identified as β -linked glucosaccharides. In view of the importance of this reaction in carbohydrate metabolism and in the mechanism of the synthesis of oligosaccharides, we report in this communication the results obtained on the identification of the substances formed from cellobiose.

Dialysed extract (5 c.c.) of *Aspergillus flavus* was added to a mixture containing 5 c.c. of 20 per cent cellobiose in 0.02 M acetate buffer (pH 5.0) and

Fig. 1. Semicircular chromatogram showing the separation of glucose and oligosaccharides formed after 15 days of incubation of cellobiose with the mycelial extract of *Aspergillus flavus*. Solvent: butanol-pyridine-water (60:40:30); reagent: aniline-hydrogen phthalate; Whatman No. 3 (25 cm. diam.). Double development.

1, Oligosaccharide (1); 2, oligosaccharide (2); 3, gentiobiose; 4, cellobiose; 5, unidentified band; 6, glucose

incubated at room temperature (21–24° C.). Aliquots were removed at known intervals and the sugars and oligosaccharides formed were separated and identified by circular paper chromatographic technique³ according to the procedure recently reported for the separation of sugars⁴. Butanol-pyridine-water (60:40:30) and butanol-acetone-water (20:70:10) were used as solvents and aniline-diphenylamine-phosphoric acid⁵ and aniline-hydrogen phthalate⁶ as reagents. Fig. 1 shows the chromatogram of the saccharides formed after fifteen days of incubation. The oligosaccharides were identified by running multisector chromatograms of the digest and a mixture of cello-dextrins obtained by deacetylation⁷ of cellulose acetolysate⁸ and gentiobiose, which was kindly supplied by Dr. W. J. Whelan, of the University College of North Wales, Bangor. It was observed that during the first 18 hr. of incubation glucose and the oligosaccharide (2) were formed, followed by the formation of oligosaccharide (1) after 72 hr. On the eighth day of incubation the oligosaccharide (3) was formed and its concentration increased at later stages. A faint band (4) appeared at the initial stages which did not increase in intensity after fifteen days of incubation. Only one of the oligosaccharides (1) corresponded with a cello-dextrin occupying the position below cellobiose on the chromatogram. The oligosaccharide (3) occupied the same position as that of gentiobiose and isomaltose. All the oligosaccharides showed reducing action towards the reagent triphenyl tetrazolium chloride. Complete hydrolysis of the oligosaccharides (1) and (2) after elution from the paper yielded glucose as the only product.

These observations indicate the occurrence of enzymes in the mould, which synthesize oligosaccharides from cellobiose by the same mechanism of transglucosidation as suggested by Pazur and French⁹ for the synthesis of oligosaccharides by the enzymic action of fungal cultures on maltose. The enzymes of *Aspergillus flavus* convert cellobiose into glucose and oligosaccharides (1) and (2) which appear in the initial stages and also convert cellobiose into gentiobiose, a conversion similar to that of maltose into isomaltose by *Penicillium chrysogenum*—Q176¹⁰ and other moulds¹¹. The gentiobiose was identified provisionally from the study of the R_f values of the substance in various solvents, the reducing action and colour reactions with aniline-diphenylamine-phosphoric acid, which was found to be a useful reagent for differentiation of sugars with 1–4 and 1–6 glycosidic linkages¹². Further work on the isolation and characterization

of the oligosaccharides and the enzymes is in progress and will be reported in a later communication.

Absorption of Phosphorus-32 from the Rabbit Vagina under Various Hormonal Conditions

It has been known for a long time that the vagina of different animals absorbs many substances, for example, poisons of various kinds, dyestuffs, semen, etc. (for references see Bengtsson¹). As the condition of the vagina is influenced by oestrogenic hormone, it is to be expected that this hormone will also influence the absorption capacity of the vagina. Baker² found in rats that the absorption of potassium ferrocyanide from the vagina changes during the course of the sexual cycle, being slowest in oestrus and most rapid in oestrated animals, that is, the absorption varies directly with the thickness and the cornification of the vaginal squamous epithelium. The following investigation was carried out in order to elucidate the influence of oestrogens on the vaginal absorption in animals with no impeding epithelium (that is, with a columnar vaginal epithelium).

Through a soft rubber catheter, 0.5–1.0 mc. phosphorus-32 in the form of disodium hydrogen phosphate was injected into the vagina of an anaesthetized rabbit. The isotope was diluted with normal saline to 2 ml.; 1.0 mc. corresponded to 100 μ gm. phosphorus. After withdrawal of the catheter, the vaginal opening was carefully closed by a soft clip. Immediately before the injection, the urinary bladder was emptied by pressing on the abdomen, and the vagina was repeatedly washed with normal saline. At various intervals (5, 10, 20, 30, 40, 70 and 120 min.) after the injection of phosphorus-32, about 1 ml. blood was removed from the ear vein and immediately centrifuged. Of the plasma, 0.1 ml. was pipetted on to an aluminium plate and the radioactivity determined by means of a Geiger-Müller tube and an electron counter. The absorption curves thus obtained were adjusted to equal height.

Thirty-six rabbits were used, eighteen of which were castrated and untreated, four were castrated and subcutaneously injected with about 5,000 i.u. oestrone in water solution ('Menformon' Pharmacia) daily for a week, four were castrated and intravenously injected with a single dose of oestrone (5,000 i.u. of the same hormonal preparation) one hour before the phosphorus-32 injection, and ten animals were normal controls (that is, not castrated). Ovariectomy was performed one to two weeks before

Fig. 1. Per cent radioactivity in the blood at various times after vaginal application of phosphorus-32. Curve 1, castrated, non-treated rabbits; curve 2, normal rabbits; curve 3, castrated rabbits, injected intravenously with oestrogen one hour before the vaginal application of phosphorus-32; curve 4, castrated rabbits, injected subcutaneously with oestrogen daily for a week before the vaginal application of phosphorus-32.

the experiments. The curves in Fig. 1 show the mean values for the different observations in the four groups.

The castrated, untreated animals (curve 1) have a slow vaginal absorption with maximum activity in the blood about 70 min. after the injection of phosphorus-32. Normal rabbits (curve 2) have a somewhat more rapid absorption, with maximum activity after about 40 min. The oestrogen-treated animals (curves 3 and 4) show the most rapid absorption, with maximum activity only about 10–20 min. after injection of phosphorus-32.

One hour after stimulation by oestrogen, the vaginal absorption was thus considerably increased. This rapid action of oestrogen on the vaginal absorption is in full agreement with other rapid oestrogenic effects on the vagina, for example, vasodilatation³ and permeability of the cell membrane to phosphate⁴.

The increase in the rate of vaginal absorption after hormonal stimulation may well be due to more than one reason: (1) the above-mentioned vasodilatation; (2) the increased penetration of phosphate through the cell membrane; and (3) possibly also an increase of the absorption surface, that is, a dilatation of the vagina. From the experiments it is impossible to know how the increase in phosphate absorption is brought about. But it seems probable that the hormonal effect on the cell membrane plays an important part. (In several other experiments, oestrogen was given intravenously at various times after the injection of phosphorus-32 in order to investigate whether a rapid increase of absorption could influence the slope of the activity curve. However, no conclusions could be drawn on this point.)

The similarity of the absorption curves for the groups treated one hour and one week before application of phosphorus-32 is surprising. The effect of oestrogen on the factors which regulate absorption (vasodilatation, phosphate penetration, etc.) can scarcely reach a maximum within one hour after hormonal stimulation. Possibly the increasing oedema and the production of mucus in the cells of the vaginal mucous membrane again decrease the absorption. This would be parallel to the observation in rats by Baker mentioned earlier²: the increasing cornification of the vaginal epithelium during oestrus diminishes the absorption.

It is curious that the activity in the blood in untreated normal and untreated castrated animals is practically unchanged from 40 to 120 min. after

the injection of phosphorus-32. The vaginal route of application of radiophosphorus in rabbits therefore represents a means of getting a stable activity in the blood; the slopes of the individual curve are, however, so variable that the method is somewhat uncertain.

Marine Invertebrate Preparations useful in the Bioassay of Acetylcholine and 5-Hydroxytryptamine

CERTAIN isolated muscle and heart preparations of marine invertebrates are highly sensitive to acetylcholine, to 5-hydroxytryptamine (enteramine, serotonin), or to both of these substances. Bao¹ was the first and Ambache and Sawaya² among the more recent to demonstrate the sensitivity to acetylcholine of muscle strips from holothurians (Echinodermata). Inhibition of heart-beat of the bivalve mollusc, *Venus mercenaria*, was first used by Welsh³ for the quantitative estimation of acetylcholine in tissue extracts. Recently, the same heart has been found to respond by increases in amplitude and frequency to low concentrations of 5-hydroxytryptamine⁴. Earlier, it had been reported^{5,6} that certain molluscan hearts had a low threshold to 5-hydroxytryptamine or tissue extracts containing this substance. At the Marine Biological Laboratory, during the summer of 1953, the need arose for the quantitative estimation of acetylcholine and 5-hydroxytryptamine in certain tissues. Several species of echinoderms and molluscs from the Plymouth region were secured, and isolated muscle and heart preparations were screened for their suitability in bioassay of these substances. Available holothurians were *Holothuria nigra*, *Oucumaria normani*, *O. elongata*, and a single specimen of *Thyone* sp. Pieces or entire lengths of the longitudinal muscle bands were dissected free from the inner body wall and set up in the manner commonly used for muscle strips during recording of contractions. In the case of *O. normani* the peristomal (pharyngeal) retractor muscles were also tried. While all these preparations contracted in low concentrations of acetylcholine, especially after eserization, the difficulties that were encountered by earlier workers^{1,7} who had used other species of holothurians were obvious. Chief among these were spontaneous contractions, tendency to contract and remain contracted after eserine, and sensitivity to mechanical stimulation after eserine. This last was especially marked in the muscles from the single specimen of *Thyone* which, otherwise, were most promising since they were not spontaneously active.

Of these holothurians from the Plymouth region, *H. nigra* was considered most suitable. Its longitudinal body-wall muscles responded to as little as 5×10^{-9} gm./ml. acetylcholine chloride before eserine and often were not spontaneously active. The response to acetylcholine was nearly maximal at 10^{-7} gm./ml. Although a low concentration of eserine (10^{-8} gm./ml.) produced or increased spontaneous activity, it lowered the threshold to acetylcholine about a hundred-fold. When an acetylcholine con-

traction was superimposed on minimal spontaneous activity, a satisfactory quantitative measure of action was obtained. Isolated muscles of *H. nigra* were kept for twenty-four hours in aerated sea-water and there was little or no change in sensitivity to acetylcholine. The responses of holothurian muscle to 5-hydroxytryptamine were not observed.

Hearts from *Pecten maximus*, *Modiolus modiolus*, *Cyprina islandica* and *Buccinum undatum* were tested for their sensitivity to acetylcholine and 5-hydroxytryptamine. The heart of *Pecten* was cannulated and perfused *in situ* and also isolated and perfused. Much difficulty was encountered in maintaining a heart with a regular beat for an adequate period of time, and the sensitivity to acetylcholine and 5-hydroxytryptamine was low. The hearts of *Modiolus* and *Cyprina* were isolated and suspended in a bath, without cannulation, after the method employed with the heart of *Venus mercenaria*³. The *Modiolus* heart had a regular beat that held for many hours, but it was extremely insensitive both to acetylcholine and 5-hydroxytryptamine. In one instance no inhibition with acetylcholine was obtained at a concentration of 10^{-6} gm./ml. and no measurable excitation with 5-hydroxytryptamine at 10^{-7} gm./ml. Higher concentrations were not tested.

Three different hearts of *Cyprina* were tested. All beat at a slow rate but with a regular rhythm. The threshold dose of acetylcholine was about 5×10^{-10} gm./ml. With increasing doses the heart-rate was slowed in a graded manner; but there was no graded decrease in amplitude. At about 10^{-8} gm./ml. the heart stopped beating. The beat was quickly restored on washing. Eserine failed to potentiate the action of acetylcholine significantly. The *Cyprina* heart responded to 5-hydroxytryptamine with an increase in amplitude and frequency. Threshold was near 10^{-10} gm./ml. and a graded action was obtained up to 10^{-6} gm./ml.

On the *Venus* heart 'Mytolon' (supplied through kindness of Sterling-Winthrop Research Institute) is the most effective known acetylcholine antagonist^{8,9}. Likewise, lysergic acid diethylamide (LSD-25) (supplied through kindness of Sandoz Products, Ltd.) is the most effective antagonist for 5-hydroxytryptamine yet found for the *Venus* heart¹¹. 'Mytolon' was found to be a highly effective antagonist for acetylcholine and LSD-25 for 5-hydroxytryptamine on the heart of *Cyprina*.

Considering relative abundance, hardness of the animals and regularity and responsiveness of the heart to the substances to be assayed, the whelk, *Buccinum*, proved most satisfactory. Hence it was used in the identification and estimation of acetylcholine and an excitator substance, probably 5-hydroxytryptamine, in molluscan tissues. A detailed account of the results will appear elsewhere. The *Buccinum* heart was removed and a cannula inserted into the ventricle, usually by way of the auricle, but sometimes by way of the aorta if the auricle was accidentally torn from the ventricle. The attachment of the thin-walled auricle to the thick-walled ventricle is delicate, and two or three separate ligatures of rather coarse thread avoided the cutting and tearing that otherwise sometimes occurred. The *Buccinum* ventricle was perfused with sea-water, as were the other molluscan hearts and holothurian muscles. It was necessary to distend the ventricle with a small head of pressure to start it beating and to introduce drugs and extracts under the same pressure used in perfusing and washing.

The *Buccinum* ventricle had thresholds to acetylcholine and 5-hydroxytryptamine near those of *Cyprina*. The response to acetylcholine, however, is a decrease in amplitude with little change in frequency. The frequency increase produced by 5-hydroxytryptamine is often accompanied by an increase in tonus. 'Mytolon' blocked acetylcholine and LSD-25 blocked 5-hydroxytryptamine, as on the *Cyprina* heart. These highly effective antagonists were used in obtaining estimates of the amounts of acetylcholine and 5-hydroxytryptamine occurring together in a given tissue. Preliminary evidence that the heart of *Venus mercenaria* has an excitatory innervation mediated by 5-hydroxytryptamine was recently presented⁴. Nerve ganglia and certain other tissues of molluscs from the Plymouth region were found to contain mixtures of heart-excitatory and -inhibiting substances. Reliable quantitative estimates could be made only when the test heart was treated with 'Mytolon' or with LSD-25 to block one or the other substance. Since leaving Plymouth, we have found by chromatography and biological tests that ganglia of *Venus mercenaria* and the whelk, *Busycon canaliculatum*, contain 5-hydroxytryptamine and acetylcholine. It is likely that these were the substances present in the tissues studied at Plymouth.

Other large molluscs were not available at Plymouth; but Prof. Brodie Hughes, at the University of Birmingham, has kindly permitted me to say that he has tested the sensitivity of the isolated heart of *Mya arenaria* to acetylcholine and has used it in the bioassay of acetylcholine in cerebrospinal fluid. A record sent me by Prof. Hughes was made in February. The record shows a decrease in amplitude of about 80 per cent when 0.005 $\mu\text{gm./ml.}$ acetylcholine was present in the bath. The decrease in amplitude with 0.008 $\mu\text{gm./ml.}$ was nearly 50 per cent and with 0.01 $\mu\text{gm./ml.}$ the amplitude was reduced to zero. Prof. Hughes has noted that *Mya* hearts become much more sensitive from the months of April to June. A similar seasonal shift in responsiveness of the *Venus* heart to acetylcholine was first noted by Prosser¹², who found them most sensitive in late winter and spring. Whether this is generally true of marine molluscs from northern waters is not known.

It is apparent from this brief survey that there are several species of marine molluscs in British waters the hearts of which may be useful in the determination and estimation of small amounts of acetylcholine and 5-hydroxytryptamine. It is also clear that there are holothurian species the muscles of which respond to low concentrations of acetylcholine.

I am indebted to the Director and staff of the Laboratory, Citadel Hill, Plymouth, for the facilities that were provided for this work.

Life-history of the Rat Lung-worm and its Migration through the Brain of its Host

THE metastrongylid lung-worm, *Angiostrongylus cantonensis* (Chen), was described from rats at Canton¹, reported by Yokogawa from Formosa², and has been found in about 5 per cent of wild brown rats, *Rattus norvegicus* (Ersl.), in Brisbane. It is now being maintained as a laboratory infection in white rats. The life-history shows some remarkable features.

The adult worms live in the pulmonary arteries. The unsegmented ova are discharged into the bloodstream and lodge as emboli in the pulmonary capillaries. They develop there into first-stage larvae, which penetrate the alveoli, and presumably pass up the trachea and are swallowed, for they can be found in the intestinal contents and eventually pass out of the host in the faeces.

Garden slugs, *Limax* spp., act as intermediate hosts, a small, black, still unidentified, species being the best. The first-stage larvae usually penetrate the foot of the slug; but developing larvae may also be found in other parts of the body-wall and in between the internal organs. The first moult occurs in about twelve days and the second about five days later, at temperatures ranging from 70° to 79° F.

The third-stage larva remains quiescent within its two cast skins until ingested by a rat, when it is

Fig. 1

Fig. 2

Figs. 1 and 2. Tracings from photomicrographs of sections of the brains of rats. Fig. 1 is from a rat twelve days, and Fig. 2 twenty-nine days, after ingestion of infective larvae. c, cerebral cortex; w, pia-arachnoid membrane; v, section of lung-worm; e, dilated vein.

set free in the stomach and moves actively down the intestine. Larvæ have been found in the lower part of the ileum less than three hours after ingestion, and have been detected in the mesentery attached to it at this time. One was seen inside a small mesenteric vein, and it is presumed that they enter the blood-stream here.

Two days after ingestion, larvæ may be found in the grey matter of the cerebral hemispheres, particularly near the anterior pole, moving about in the cerebral tissue without causing any apparent damage (Fig. 1). They grow, and about the twelfth day the final moult occurs. The immature adults then emerge on the surface of the cerebrum, where they move about freely in the sub-arachnoid space and grow rapidly. The vessels of the pia-arachnoid become greatly dilated, and there is considerable cellular infiltration (Fig. 2).

On the twenty-ninth day after ingestion, the young adults begin their journey to the lungs. They have been recovered from the external jugular vein, left superior vena cava and right ventricle between the twenty-ninth and thirty-first days. By the thirty-second day, migration is usually complete, and all worms are found in the pulmonary arteries. Egg-laying begins a few days later, and first-stage larvæ appear in the faeces of the host between the fortieth and forty-fifth days.

The rats show no noticeable ill-effects from the quite gross lesions produced in the meninges and lungs.

This appears to be the first record of a parasitic nematode requiring a prolonged sojourn in the brain of its final host, before migrating to its definitive site at a relatively advanced stage of development. A detailed account of the work will be published elsewhere.

Allometric Growth in the Nematoda

ALLOMETRIC growth has been studied, and shown to occur, in a large number of different animals; but the Nematoda do not appear to have been studied in this way. This is especially surprising in view of the simple shape of the parasitic members of this group and the extent to which the systematics of the group are dependent upon simple measurements of the individuals and of their constituent parts and, to a lesser degree, upon the ratios of these parts. In such cases allometric growth must be considered before too much stress is laid upon differences in ratios.

Data on the dimensions of the nematode species *Toxascaris leonina* (von Linst., 1902) have been gathered during a study of host specificity and variation within this species, and have been utilized to determine whether or not allometric growth occurs in the following cases: head and body width; growth in length of the oesophagus, the tail and the cervical alæ in relation to the body-length. The results show that allometric growth occurs in this species in all

the relationships considered except, possibly, in the cases of body-breadth and total body-length, and oesophageal breadth and oesophageal length.

In the equation for allometric growth, $y = bx^k$, the value of b is of no biological significance since it simply gives the length of y when $x = 1$ and its value is dependent upon the units used in its calculation. k , however, is of value since it indicates the differences between the rates of growth of the two parts under consideration. In Table 1 the values of k obtained for the different growth-rates compared are given.

Table 1

Relationship considered	Allometric constant
Oesophageal length : Body length	0.36
Cervical alæ length : Body length	0.41
Tail length, ♀ : Body length	0.76
Tail length, ♂ : Body length	0.59
Diameter of the head : Body length (whole)	0.46

These values of k indicate that the simple ratios of these dimensions must vary considerably in individuals of different total body-length and that such simple ratios must be treated, in systematic, with a certain amount of reserve.

The results obtained from a study of the relationships between the total body-length and body-breadth and oesophageal length and oesophageal breadth suggest that these relationships are isometric. These conclusions must, however, be treated with caution as the width of the individuals is the dimension most affected by preservation.

Liberation of Boron from 'Pyrex' and 'Hysil' Glass in Relation to Plant Growth in Water Culture

It is well known that plants in water culture may absorb appreciable quantities of boron from glassware such as 'Pyrex' and 'Hysil', which contain borosilicates. The literature has been reviewed by Hewitt¹ in relation to water culture techniques. The possibility of contamination resulting from the use of this type of laboratory glassware in preparing culture solutions has not, however, been generally recognized.

Using the method described by Hatcher and Wilcox², it was found that the boron content of copper-distilled water which had been boiled for one hour in a 'Pyrex' flask was 0.074 p.p.m. A comparable value was found for 'Hysil' flasks, namely, 0.070 p.p.m. boron. No boron could be detected in the original distilled water.

The response of flax seedlings to water which had been boiled for one hour in a 'Hysil' flask was examined as follows: the plants were grown in 1 lb. jam jars (soda glass) containing 800 ml. of a boron-free nutrient solution. 'Hysil'-boiled water was supplied in varying amounts up to 7.33 per cent by volume of the nutrient solution, which was renewed weekly, but not aerated. Ten seedlings were grown in each jar and after three weeks growth under glass in July the dry weights of shoots and roots were determined.

Fig. 1

The results are summarized in Fig. 1. It will be noted that where the proportion of 'Hysil'-boiled water exceeded 4.33 per cent of the total volume of nutrient solution, significant increases in the dry weights of both shoot and root resulted. The concentration of boron at this dilution of the 'Hysil'-boiled water was only 0.0030 p.p.m.

These findings arose from attempts made in this department to verify the claim of Eaton³ that β -indolyl acetic acid may, to some extent, replace boron as an essential element in plant growth. When aqueous solutions of this acid prepared in 'Hysil' vessels were added to boron-deficient nutrient solutions significant increases in the growth of flax were frequently obtained. This result can now be attributed, at least in part, to the boron liberated from the glassware.

In recent years much attention has been centred on the testing of a wide range of organic compounds for biological activity. It is now evident that where the level of boron is sub-optimal for the growth of the plant or plant organ, or is quite unknown, precautions should be observed to ensure that, in the preparations of solutions for test, no contamination with borosilicate glassware has occurred.

We are indebted to Dr. T. H. Rose and Mr. T. Williams, of the National Agricultural Advisory Service, Wye, for the boron estimations.

Sharpening the Microtome Knife

SEVERAL articles have been written on the most suitable method of sharpening the knife of a microtome. The usual manner of sharpening is grinding, honing, polishing and stropping, and there are several different methods for each of those operations. There is obviously a lack of a quantitative measuring method by means of which the result of different sharpening methods can be tested. The only fairly reliable method still used is the one indicated by von Mohl¹.

The edge of the microtome knife is formed by the line of intersection of the facet surfaces. Decisive for the quality of the knife are evenness and surface finish. Therefore, a good sharpening method must result in both these qualities for the facet surfaces. Just as important is a measuring method which gives an absolute measurement of the sharpening result.

A machining method which satisfies the highest demands of evenness and surface finish of steel is lapping against cast-iron. This method is, as a rule, used by the measurement workshops in factories where precision goods are manufactured. It has proved extremely advantageous for the purpose of sharpening microtome knives. Owing to its speed with regard to removing the material and its performance with regard to the evenness and surface finish, it alone can replace grinding, honing, polishing and stropping.

By means of multiple interference microscopy, according to Ingelstam², it is possible to check the machined facet surfaces quantitatively. By using this method, deficiencies in evenness and surface finish can be measured to an accuracy of about 50 Å. The result of different sharpening procedures can thus be given in absolute measurement. The facet surface of a microtome knife direct from the factory (Fig. 1), and a lapped knife (Fig. 2), are shown on the accompanying interferograms ($\times 600$). The interference fringes give a direct profile curve of the facet surface. The new knife shows signs of machining at a depth of 2000 Å, that is, rather a good surface finish but, on the other hand, variations in evenness of about 3000 Å longitudinally and finally a considerable curving of the facet surface, which means that the clearance angle of the knife can never be adjusted against the block of tissue. The figures corresponding to the lapped surface are 50–200 and 500 Å, respectively.

A more detailed report of this method will be published later.

I am indebted to Mr. Erik Gislén, chief engineer, and the SKF Factory, Göteborg, for their kind assistance and for the facilities placed at my disposal which made it possible to carry out this investigation. The cost of the investigation was defrayed by grant from the Swedish Medical Science Research Council.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Monday, May 17

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE, PHILOSOPHY OF SCIENCE GROUP (in the Joint Staff Common Room, University College, Gower Street, London, W.O.1), at 5.30 p.m.—Prof. Wilfrid V. Quine: "The Nature of Mathematical Truth".

UNIVERSITY OF LONDON (at Guy's Hospital Medical School, St. Thomas Street, London, S.E.1), at 5.30 p.m.—Dr. B. Brodie (U.S.A.): "Biochemical and Clinical Implications of Studies in Drug Metabolism". (Further Lecture on May 19.)

UNIVERSITY OF LONDON (at Queen Mary College, Mile End Road, London, E.1), at 5.30 p.m.—Prof. Werner Fenchel: "Duality in the Theory of Convex Functions". (Further Lecture on May 18 at above address, and on May 21 at University of London, Senate House, London, W.O.1.)

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.O.2), at 6 p.m.—Dr. Henry Phillips: "The Chemistry of Leather". (Cantor Lecture.) (Further Lectures on May 24 and 31.)

Monday, May 17—Thursday, May 20

ILLUMINATING ENGINEERING SOCIETY (at the Town Hall, Torquay)—Twenty-ninth Annual Conference: "Electricity and the Country-side".

Monday, May 17—Friday, May 21

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.O.2), at 6 p.m.—Dr. Henry Phillips: "The Chemistry of Leather". (Cantor Lecture.) (Further Lectures on May 24 and 31.)

Tuesday, May 18

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam Street, Adelphi, London, W.O.2), at 5.15 p.m.—Sir William Halcrow: "Engineering Developments in Central Africa".

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Annual General Meeting. Mr. W. Leonard Hill: "Making Known" (Chairman's Address).

UNIVERSITY OF LONDON (at the Institute of Archaeology, Inner Circle, Regent's Park, London, N.W.1), at 8.15 p.m.—Mr. A. Digby: "Recent Work in Archaeology outside Europe", (2) "Central America".

Tuesday, May 18—Friday, May 21

ILLUMINATING ENGINEERING SOCIETY (at Southport)—Summer Meeting.

Wednesday, May 19

PHYSICAL SOCIETY and the INSTITUTE OF PHYSICS (in the Physics Lecture Theatre, University College, Gower Street, London, W.O.1), at 4.15 p.m.—Joint meeting on "Electron Physics".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Scientific Papers.

ROYAL SOCIETY OF MEDICINE, COMPARATIVE MEDICINE SECTION (at 1 Wimpole Street, London, W.1), at 5 p.m.—Annual General Meeting, followed by discussion on "Physiological and Pathological Aspects of Locomotion in Man and Animals".

SYNTHETIC ASSOCIATION (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Colloquium on "The Species Concept in Palaeontology".

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.O.1), at 5.15 p.m.—Mr. J. Durbin and Mr. A. Stuart: "Non-Response and Clustering in Sample Surveys: an Experimental Study".

Thursday, May 20

ROYAL AERONAUTICAL SOCIETY (at the Royal Institution, Albemarle Street, London, W.1), at 6 p.m.—Dr. A. R. Russell: "The Choice of Power Units for Civil Aeroplanes" (42nd Wilbur Wright Memorial Lecture).

Friday, May 21

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. R. S. Oliver: "Visual Aids to Bad-Weather Approach".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. A. C. B. Lovell: "Britain's Giant Radio Telescope".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SENIOR SCIENTIFIC OFFICER (with a university degree of high standard or equivalent qualifications in appropriate field, and with several years relevant research experience) in the Department of Supply, Defence Standards Laboratories, Maribyrnong, Victoria, Australia, for research into the development and application of techniques of optical instrument technology, photometry and colorimetry—The Senior Representative (A.P.13), Department of Supply, Australia House, The Strand, London, W.O.2 (May 20).

ASSISTANT LECTURER, LECTURER or SENIOR LECTURER IN ORGANIC CHEMISTRY at the University College of Khartoum—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.O.1 (May 21).

HEAD (with a higher degree, recent experience in research, teaching experience in a university or technical college, and/or industrial experience) of THE DEPARTMENT OF METALLURGY, County Technical College, Wednesbury—The Director of Education, Department F.S., County Education Office, Stafford (May 22).

TECHNICIAN (preferably with some experience in photography and/or microtechnique) in THE DEPARTMENT OF BIOLOGY—The Registrar, University College of Swansea, Singleton Park, Swansea (May 22).

CHAIR OF APPLIED METEOROLOGY—The Secretary and Registrar, University College of North Wales, Bangor, N. Wales (May 24).

LECTURER (with special qualifications in palaeontology) in GEOLOGY—The Secretary, University of Durham, 28 North Bailey, Durham (May 24).

SENIOR AGRICULTURAL ECONOMIST and an AGRICULTURAL ECONOMIST (with a degree in economics or agriculture, and with research experience in economics or agricultural economics)—The Secretary, School of Agriculture, The University, Cambridge (May 25).

ASSISTANT LECTURER IN PURE MATHEMATICS and an ASSISTANT LECTURER IN GEOGRAPHY—The Registrar, King's College, Strand, London, W.O.2 (May 28).

ASSISTANT LECTURER, Grade III, or LECTURER, Grade II (preferably with a special knowledge in vertebrate palaeontology or palaeobotany) in THE DEPARTMENT OF GEOLOGY—The Registrar and Secretary, The University, Bristol (May 29).

ASSISTANT LECTURER in GEOLOGY—The Registrar, University College of South Wales and Glamorgan, Cathays Park, Cardiff (May 29).

SENIOR LECTURER in SOCIAL STUDIES, a SENIOR LECTURER in CHEMICAL ENGINEERING, a LECTURER in MATHEMATICS, and a LECTURER in TEXTILE SCIENCE—The Principal, Royal Technical College, Peel Park, Belfast 5 (May 29).

ASSISTANT LECTURER or LECTURER (with special qualifications in inorganic chemistry) in THE DEPARTMENT OF CHEMISTRY—The Registrar, University College of Wales, Aberystwyth (May 30).

LECTURER in GEOLOGY with special reference to Stratigraphy—The Secretary, Queen's University, Belfast (May 30).

ASSISTANT LECTURER (preferably with an interest in Western Europe and/or climatology) in GEOGRAPHY—The Secretary, University College London, Gower Street, London, W.O.1 (May 31).

LECTURER (graduate in agriculture and specialised in poultry) in POULTRY, at Gwehi Agricultural College, Southern Rhodesia—The Secretary, Rhodesia House, 420 Strand, London, W.C.2 (May 31).

LECTURER (with university teaching qualifications and experience) in STATISTICS or STATISTICAL MATHEMATICS, at the University, Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.O.1 (Hong Kong, May 31).

MINES AGENS FELLOW (with Ph.D. degree or its equivalent in chemistry or biochemistry) in RADIOPHYSICS, in the Department of Chemical Pathology, to carry out original work on steroid hormones—The Secretary, King's College Hospital Medical School, Denmark Hill, London, S.E.5 (May 31).

PLANT BREEDER (science graduate with aptitude for research, and preferably with postgraduate training and experience in plant breeding, statistics, field experimentation and soil science) in THE FIELD HUSBANDRY BRANCH, Department of Research and Specialist Services, Southern Rhodesia Government—The Secretary, Rhodesia House, 420 Strand, London, W.C.2 (May 31).

ASSISTANTS in THEORETICAL OR EXPERIMENTAL PHYSICS in the Department of Natural Philosophy—The Secretary, The University, Aberdeen (June 1).

DEMONSTRATOR (with a good honours degree in physiology, biochemistry or chemistry with subsidiary physiology) in CHEMICAL PHYSIOLOGY—The Registrar, The University, Manchester (June 1).

RESEARCH ASSISTANT in MATHEMATICAL STATISTICS and a RESEARCH ASSISTANT in NUMERICAL ANALYSIS in the Department of Applied Mathematics—The Registrar, The University, Liverpool (June 1).

CHIEF OF RESEARCH AND DEVELOPMENT, LEADER OF CHEMISTRY SECTION, LEADER OF METALLURGY SECTION, LEADER OF ENGINEERING AND CHEMICAL ENGINEERING SECTIONS, and a SENIOR MATHEMATICAL PHYSICIST, with the Australian Atomic Energy Commission, Sydney—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Alfred House, Kingsway, London, W.O.2 (Sydney, June 5).

LECTURER (with a good honours degree and practical experience, and preferably with research experience) in CIVIL ENGINEERING—The Registrar, The University, Nottingham (June 5).

LECTURERS (2) in GEOLOGY (General and Economic)—The Secretary, The University, Edinburgh (June 5).

ASSISTANT LECTURER in CHEMISTRY at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.O.1 (June 8).

ASSISTANT AGRICULTURAL ECONOMIST (graduate in economics and/or agriculture)—The Registrar, The University, Bristol 8 (June 12).

LECTURER in THE DEPARTMENT OF BIOCHEMISTRY—The Secretary, The University, Edinburgh (June 15).

RESEARCH FELLOW (with an honours degree in chemistry or agricultural chemistry, and experience in the chemistry of soils) in SOIL CHEMISTRY, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.O.1 (June 20).

LECTURER in CROP PRODUCTION (Plant Breeding), a LECTURER in ANIMAL PRODUCTION, a LECTURER in ANIMAL HEALTH, and a LECTURER in AGRICULTURAL ENGINEERING, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.O.1 (June 20).

RESEARCH STUDENTS (with the degree of Bachelor or Master of a British University, other than Manchester) in SCIENCE—The Registrar, The University, Manchester (July 1).

SENIOR LECTURER in METALLURGY at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.O.1 (New Zealand, July 1).

SENIOR LECTURER IN PHYSICS at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 6 Gordon Square, London, W.C.1 (South Africa, July 1).

ASSISTANT LECTURER, Grade B, IN THE DEPARTMENT OF CHEMISTRY, College of Technology and Commerce, Cardiff—The Director of Education, City Hall, Cardiff.

ASSISTANT (medically qualified, and preferably with experience in bacteriology) in the BACTERIOLOGY DEPARTMENT—The Secretary, University College Hospital Medical School, University Street, London, W.C.1.

ENGINEER (Basic grade) to assist in the design and development of mechanical equipment, such as laboratory instruments and light and medium mechanical engineering devices and prototypes to scientists' and Service requirements—The Administrative Officer (Recruitment), Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 58/W.G.B.2.

ENGINEER (with first- or second-class honours degree or equivalent in mechanical or aeronautical engineering, and with practical experience), at the Royal Aircraft Establishment, Farnborough, Hants, for work in the Armament Division on research and development of air armaments and their installation in aircraft—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting 0.903/54A.

LECTURER IN MATHEMATICS and a **LECTURER IN PHYSICS** at the Higher Teachers' Training College, Baghdad—The Cultural Attaché, Iraqi Embassy, 22 Queen's Gate, London, S.W.7.

LECTURER (with previous university teaching experience, and preferably with an interest in physiology and ecology) in Botany—The Principal, Sir John Cass College, Jewry Street, London, E.C.3.

PHYSICIST (with first- or second-class honours degree in physics, and a bias towards physical chemistry and physics of solids), at the Royal Aircraft Establishment, Farnborough, to work with the Electrical Engineering Department on investigations concerning physics of solids, particularly with regard to formation of oxide and graphite films on metals by rubbing action of graphite brushes, and study of factors influencing oxidation of petrol and oils, and consequent fire risk with electrical equipment so contaminated—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.119/54A.

PLANT PATHOLOGIST or PLANT PHYSIOLOGIST (with a degree in natural science and training in plant pathology or plant physiology, and preferably with experience in coffee diseases) in Kenya, to investigate diseases of coffee, at the Coffee Research Station, Bura—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting O.D.R.03/7015.

RESEARCH ASSISTANT (honours graduate, with zoology or physiology as principal subject, and preferably with a knowledge of physics and/or postgraduate laboratory experience) in the RADIOLOGY LABORATORIES—The Administrative Officer, Christie Hospital and Holt Radium Institute, Manchester 20.

SENIOR EXPERIMENTAL OFFICER (with H.S.C. (science) or equivalent qualification) to act as Chief Programmer for an electronic digital computer, and to advise on the best methods of proposing problems for the machine—The Administrative Officer (Recruitment), Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 133/W.G.B.2.

SENIOR LECTURER IN PHARMACOLOGY and a **SENIOR LECTURER IN PHARMACEUTICS**—The Registrar, College of Technology and Commerce, The Newark, Leicester.

TWO SHILLINGS

THE *Newton*

LONG WORKING DISTANCE ATTACHMENT

... provides a working distance of 12.8 mm. between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm. objective

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

How SIMPLE is a VALVELESS Vacuum System?

A valveless vacuum system provides the simplest and most economical arrangement for the high vacuum processing. Frequent rough pumping, however, through the hot vapour pump causes the operating fluid to be carried over as mist into the backing system.

EDWARDS have solved this problem by introducing a simple and highly effective FLUID ECONOMISER to recover and return the greater part of the exhaust mist back to the vapour pump—resulting in more operating cycles with less maintenance.

The illustration shows our well-known F208 three-stage vapour pump fitted with FLUID ECONOMISER. Vacuum, better than 5×10^{-6} mm Hg. Speed, 70–80 litres/sec.

EDUCATIONAL TASKS IN BRITAIN

IT is now generally appreciated that the shortage of trained man-power in Britain is the basis of the shortage of school-teachers—and particularly teachers of science—about which there has been much discussion in recent months. In the House of Commons on April 27 the matter was debated and some suggestions offered (see *Nature*, June 12, p. 1105); but clearly the fundamental thing is further support for education. This may well involve sacrifices in other parts of the social services, and before this could be contemplated, an informed public opinion prepared to give to education its proper place in the national life is essential. The creation of such a public opinion is itself, in the view of Mr. Eric James, High Master of Manchester Grammar School, perhaps the greatest of our educational tasks and the basis for all other reforms—the supply of teachers, an adequate building programme for schools and for technical colleges, the reform of the content of education, and administration of educational policy. Only if it learns to give to education its true importance, urges Mr. James, can democracy prosper, either materially or spiritually.

The two *Planning* broadsheets on "Schools under Pressure" and the debate in Parliament, like discussions at educational conferences earlier this year, show how far we are yet from this position, and how much remains to be done to secure the formulation of an adequate policy at all levels of education, let alone the allocation of resources sufficient to implement it. The supply of science teachers is only one facet of the problem, though it well illustrates the hopelessness of the situation if care is not taken to align policy with what is practicable rather than what is theoretically desirable. It is, as Mr. James notes, the most immediately dangerous aspect of the wider problem of the absolute shortage of natural ability, particularly in scientific fields, caused by the increasing demands which our civilization makes for high ability.

Whether the failure to recognize this is wilful or not, the consequence will be the same: as Mr. James put it, in the conditions of modern life the rule is absolute; the race which does not value trained intelligence is doomed. It will matter little what other excellences our educational institutions possess if they fail to recognize and foster high ability, wherever it is found, as well as to meet the demands which democracy makes on the wisdom, integrity and sense of responsibility of ordinary people. Perhaps the most disturbing features of the present situation are that so many influences are tending to weaken whatever contribution our educational system has hitherto been able to make towards the development of such wisdom, integrity or sense of responsibility, and that this tendency is encouraged by certain features of party politics.

We can scarcely expect, therefore, that either political party will formulate an adequate educational policy and implement it with resources which are in

keeping with what is required on a realistic view of national needs without a good deal of pressure from independent organizations and individuals as well as from those who do not allow a particular party allegiance to inhibit such a realistic view. Incidentally, a welcome feature of Dr. W. Idris Jones's presidential address, "Energy for Britain—the Decades Ahead", to the Institute of Fuel on April 8, was the clarity with which he emphasized the dependence of the developments he forecast in fuel economy, the reduction in atmospheric pollution and increase in efficiency of fuel-burning, on more training and the diffusion of adequate technical and scientific knowledge, as well as on adequate research and development. More people, from directors and managers downwards, must become more conversant with the efficient use of fuel and energy. Whether the challenge which the next half-century will present to men of foresight, courage, adaptability and creativeness is met depends largely on the adequacy of our policy for education, general as well as technical and technological.

Nevertheless, the Parliamentary Secretary to the Ministry of Education, replying on May 11 in an adjournment debate on technical education, particularly in Sunderland, once again revealed the limitations of the Government in this respect. New buildings and extensions to existing buildings for technical education are now being approved, he claimed, at the rate of about £4.5 million a year, while between January 1, 1948, and February 1954 projects valued at £11.5 million had been completed. In February 1954, projects for more than £17 million were under construction but not yet completed, while projects amounting to £6.5 million in the 1953–54 and 1954–55 programmes had been approved but not yet started.

Nowhere did he give a hint that the Government has a policy for technical education, and that this has been thought out in regard to the needs of technological education and the resources available; it is not clear how the selection was made of the twenty-three technical colleges which he said had been authorized, to run the courses receiving 75 per cent instead of 60 per cent grants from the Ministry.

Clearly the need is for an all-party approach, able to eliminate local or sectional prejudice and pressures, and facilitate the acceptance of sacrifices on non-essentials as well as to improvise short-term remedial measures and to formulate and execute a long-term policy. Besides clear thinking, there must be an end to the present policy of drift, which is hindering the development of technological and technical education, no less than that of primary and secondary education. Scientists who understand the way in which the existing deficiencies in technical colleges and in technological education affect industrial development and efficiency, and the repercussions which the shortage of science teachers can have on the supply of scientists for our research institutions and universities as well as for industry and the Departments of State, will not imagine that the problem can be dealt with in isolation. Dr. Idris Jones has set an example to be followed by others

as opportunity offers. The full support of men of science should be given to those who urge on the Government the imperative need of immediate and concerted action, both to increase the supply of science teachers in particular and to alleviate the over-crowding of classes and the defects in school buildings and technical colleges on which the Select Committee on Estimates has commented so forcefully.

A CHEMIST'S CONTRIBUTION TO COSMOLOGY

The Planets

Their Origin and Development. By Harold C. Urey. (Yale University: Mrs. Hespera Ely Silliman Memorial Lectures.) Pp. xvii+245. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1952.) 30s. net.

THE origin and development of the solar system has always been, and seems likely to be for a long time, an outstandingly difficult subject. It has been written about it, often in happy ignorance of the complexity of the problem; the accumulation of relevant observational data in modern times has increased rather than lessened the formidable task of the cosmologist.

Earlier theories were largely concerned with dynamical arguments, including gravitation, and these remain as a control to any new theory. To bring modern spectroscopic observations of the sun and planets into line with the data involves extensive incursions into the domains of physics, chemistry and geology, and into areas where, at best, the data are fragmentary and where, at worst, the 'system' available for study, up to the present, is not reproducible at will, and must be inferred most part by formulae that depend on data derived from laboratory data. Thus, the system of thought that has so successfully resolved many of the problems of physics is applicable only with severe limitations; each writer therefore tends to propose a new scheme, with *ad hoc* hypotheses to cover some of the phenomena that do not fall naturally into place.

Some twenty or thirty years ago it was generally recognized that the difficulty was not so much to discriminate among hypotheses as to find one single theory that fitted all the observations. More recently there has been a spate of new theories, often characterized by boldness of imagination. The vast developments in physics and chemistry make it difficult to find investigators with the imagination, breadth of knowledge and mathematical technique to make the grand synthesis. To master even the current literature requires, in addition, great energy and enthusiasm. It is no exaggeration to say that the author of this book, Prof. H. C. Urey, is one of the few men of science possessing such an array of talents.

Prof. Urey, as one of the world's leading chemists, is apologetic at his entry into cosmology: but he has no need to apologize, for many of the arguments depend on the laws of physical chemistry, with less extrapolation than is often the case with physical laws. His enthusiasm is bubbling over right through the book, and, indeed, it is for this reason that the

treatise makes rather slow reading, for to the agile mind of the author a pedestrian elaboration of his definitions and arguments must seem a little irksome; and it is perhaps better so, for in cosmological discussion one cannot expound along a single track—the simile of a network is more appropriate. At the end (Chapter 7) Prof. Urey summarizes his scheme and conclusions; in some ways it would have been much more helpful to the reader to put this chapter at the beginning as a guide. As it is, one does not easily gather from a direct reading of the book what is the author's plan of presentation. Prof. Urey has obviously taken great pains to marshal all the relevant material and to do full justice to the views of others, and this, particularly on the physical chemical side, makes his book a valuable work of reference. There are some misprints that no doubt will be corrected in a future edition.

Roughly speaking, Urey postulates a 'cold origin' for the planets as distinct from the 'hot origin' of the older theories. The development proceeds from a solar dust cloud, consisting of gas and dust, from which, by contraction, the central temperature rose until the carbon cycle continued the development of the central portion as a star. The outer disk-like part broke up into large masses, which (presumably) constituted what the author calls "preprotoplanets" and "early protoplanets"; what is to be understood by these terms is not made at all clear, but in Table 19 they are indicated as consisting of gas, dust and planetesimals. Now what is meant by "planetesimals" is not easy to grasp: the word trickles in unobtrusively on p. 27 ("the surface [of the moon] was thoroughly cold when these planetesimals fell"), and on p. 31 there is mention of "the theory that the planets accumulated from particles originally of small size", but presumably these bodies are not to be identified with the planetesimals of Chamberlin and Moulton. Some planetesimals appear to be like iron or stony meteorites and may perhaps be of the size of small minor planets, but in a future edition (and one may certainly hope that the author will continue to develop the ideas so refreshingly set out in this book) no doubt a more precise indication will be given.

The next stage is the onset of condensation, at temperatures comparable with those existing now at corresponding distances from the sun, of the preprotoplanets. The chemical state of the elements and compounds present is inferred from the ordinary laws of chemical equilibrium. An important mechanism of aggregation is the coagulating effect of condensed vapours such as water and ammonia. This stage is invoked in order to account for the retention of some of the volatile constituents, such as water and nitrogen, which for the most part escape into space. Adiabatic compression of the gas now raises the temperature to something of the order of 2,000° K., and during this hot stage, involving volatilization of some of the silicates, small bodies evaporate, iron-nickel alloy is formed in the larger bodies, and the largest bodies form this alloy in their outer parts while maintaining cool interiors. This chaotic state is, of course, difficult to follow through in detail, but during the contraction the insulating effect of the gas is held to be important, so that at the end of this stage the iron-nickel phase (arising from reduction of iron oxides) will not in all the planets have formed a core. Following this contraction, the cooling gives rise to a further low-temperature stage of consolidation, with the continued

escape of gases from the outer parts, until a final stage is reached in which the planets have assumed something like their present constitution. It is, of course, impracticable even to outline here the supposed life-histories of the planets separately.

One distinctive feature, however, of the later stage of the evolution of the earth must be cited. The author rediscusses the secular accelerations of the sun and moon following the treatment by Jeffreys, except that a possible change in the moment of inertia of the earth is allowed for. The consequences are interesting: the moment of inertia is shown to decrease with time, causing a decrease in the length of the day of the order found by Brouwer. This is held to result from the progressive flow of iron from the mantle to the core; just how this flow is compatible with the constitution of the mantle is by no means clear, but if it is assumed that vertical channels are formed, it is considered that iron may separate out from the silicate phase of the mantle and coalesce into drops which could penetrate as a liquid through these channels. This separation has not taken place in Mars and the moon, and the author suggests that the formation of a core may help to provide the energy for the formation of mountains. At present one can say so little about the viscosity and perhaps the microstructure of the interior of the earth that one ought to welcome this new hypothesis (which is presented quantitatively so far as the data allow) in the hope that it may stimulate further researches.

Prof. Urey's chemical training gives a freshening aspect to his review of dynamical and thermodynamical theories, and it is of especial value in discussions of the origin and composition of meteorites and of comets. He inclines to Whipple's 1950 theory of the formation of comets; unfortunately, Lyttleton's dynamical work has been published too recently to receive notice from Prof. Urey. One continues to marvel, indeed, that the author can have found so much time and energy to delve deeply into both early and recent writings on so many topics, and one is left with the impression that present-day cosmology is somewhat like the earlier stages of the solar system before its members settled down to their present orderly arrangement. It may be predicted that ultimately the ordered knowledge of our system will owe a debt to Prof. Urey's criticism and imagination.

R. STONELEY

PLANT-GEOGRAPHY ANCIENT AND MODERN

The Geography of the Flowering Plants

By Prof. Ronald Good. Second edition. Pp. xiv + 452 + 25 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1953.) 50s. net.

THAT the plant-covering of the world varies greatly from region to region, each having its peculiar or especially abundant plants, came vividly to the notice of the ancient Greeks in the fourth century B.C. when Alexander's armies occupied Egypt, crossed Persia and Afghanistan and entered the Indian subcontinent. In these eastern lands they met a diversity of vegetational types previously unknown, and they were quick to associate them with differences of climate and soil. Displaying an acuteness which commands respect even now, they recog-

nized generic resemblance and specific divergence between plants of different regions. Of this the Indian banyan (*Ficus benghalensis*) supplies a remarkable example. Notwithstanding its aerial roots and unusual habit of growth, its entire leaves and small fruit, the Greeks classed it as a kind of fig ($\sigma\upsilon\chi\eta$). Although they found an ivy (*Hedera nepalensis*) on a mountain of the western Himalaya (a find of special interest since ivy could not be made to grow in Babylon despite persistent attempts to naturalize it there), Alexander's men noted that scarcely a tree or shrub or herbaceous plant of India agreed with those of their native Hellas.

Observations such as these form the basic material of plant-geography. Theophrastus (b. 370 B.C.), who recorded and correlated so many of them, may accordingly be honoured as the founder of descriptive phytogeography; but not until the nineteenth century did it develop into an important scientific study. In the third quarter of that century its leaders were Alphonse de Candolle of Geneva and Sir Joseph Hooker of Kew, and in the last quarter the Germans Grisebach, Engler, Drude and A. F. Schimper. Since the publication of their works, further exploration and collecting, and study in the fields of taxonomy, ecology, floristics and cytology, have assembled so much extra information relevant to plant-geography that new surveys are urgently required but have become more and more difficult to prepare. Three major works in recent years have attempted to provide introductions and guides to this bewildering accumulation of facts and hypotheses, namely, S. A. Cain's "Foundations of Plant Geography" (1944), R. D'O. Good's "The Geography of the Flowering Plants" (1947 and 1953) and L. Croizat's "Manual of Phytogeography" (1952). None makes the others redundant. Of these, Good's book, which has now reached a second edition, is primarily a survey of the distribution of systematic plant-groups throughout the world to-day and of the factors controlling this distribution. It is the only modern text-book in English which makes such a global survey.

In general, the new edition (1953) of "The Geography of the Flowering Plants" agrees with the earlier edition (1947). It is, however, fifty pages longer. Comparison of the two editions page by page reveals minor and major changes throughout, these ranging from slight emendations of wording and the correction of errors to lengthy new passages which incorporate new material or give additional emphasis. This revision, covering illustrations and maps as well as text, has added much to its value. Especially worthy of note is the re-drafted classification of the world into floristic regions and the new map illustrating this. Inevitably in a work of such wide scope there are minor matters which have escaped emendation, the following being a few examples. The name Trapaceae (p. 63) has precedence over Hydrocaryaceae. The family Tropaeolaceae (p. 64), credited with thirty species, probably comprises about sixty-five species. *Davidia* (p. 120) is not a Himalayan but a Chinese genus. Sources of information on *Rhododendron* (p. 152) later and more comprehensive than those cited are the *Rhododendron* Society's "Species of *Rhododendron*" (1930) and papers by Cowan and Davidian in the Royal Horticultural Society's "Rhododendron Year Book". The name *Tofieldia palustris* (p. 166) should be corrected to *T. pusilla*, as pointed out in *J. Linn. Soc., Bot.*, 53, 194-204 (1947), where maps of distribution will be

found. Happily, *Delonix regia* (p. 213) still grows wild in a limited area of Madagascar.

The book concludes with a bibliography increased to 629 entries as against 295 in the first edition. Its value would be much greater had the author inserted page references. The extent and importance of a paper are rarely evident from its title alone; page references indicate to the experienced whether it is likely to be worth while making a journey to consult a work, contriving to borrow it or having a transcript or photostat made, for in no one library will the reader find available all the works cited here; hence, the omission of page references gives the bibliography an unfinished slipshod appearance out of keeping with the care bestowed upon the rest of the book. Among papers meriting inclusion are: R. Pampanini, "Essai sur la géographie botanique des Alpes" (*Mém. Soc. Fribourg Sci. Nat. Géol. Geogr.*, 3, fasc. 1; 215 pages; 159 distributional maps; 1903); A. Eig, "Les éléments et les groupes phytogéographiques auxiliaires dans la flore palestinienne" (*Fedde, Repert. Sp. Nov., Bot.*, 63, 201+120 pages; 1931), whence come the terms "Irano-Turanian", "Saharo-Sindian" and "Sudan-Deccan" used by writers on the flora of the Near East; and Hui-Lin Li, "The Phytogeographic divisions of China" (*Proc. Acad. Nat. Sci. Philadelphia*, 46, 249-277; 1944). Backer's work on Krakatau, cited as "n.d.", was published late in 1929. Strangely enough, the author fails to date precisely his own papers on *Empetrum* (actually 1927) and *Cremanthodium* (actually 1929). These blemishes detract little, however, from the worth of the book as a whole, which is well written and brings together much information not readily available elsewhere. All who use the first edition for teaching purposes would do well to acquire this enlarged and amended new edition. Those unacquainted with the book at all will find it a sound introduction to a vast and interesting field of study.

W. T. STEARN

CALCULUS OF VARIATIONS

Calculus of Variations by Parallel Displacement
By Prof. W. S. Kimball. Pp. viii+543. (London: Butterworths Scientific Publications, Ltd., 1952.) 50s. net.

IN a series of papers published in the *Philosophical Magazine* since 1937, Prof. W. S. Kimball has put forward new basic conditions in the calculus of variations. Their distinctive feature is that they are obtained by differentiation of a line integral. It is claimed that this method, which does not use what is generally called the fundamental lemma of the calculus of variations, has several advantages, and its application gives two new working-rules for the solution of examples. The book under review starts with an account of these new methods and combines them with the classical methods of Euler, Lagrange, Jacobi, Hilbert, Weierstrass and others to form a comprehensive treatise on the subject.

The preface and introduction emphasize that in this book all the principal expressions, both new and old, are obtained as rates of change. This is shown, in considerable detail, in Chapters 1-3. Chapters 4 and 5 show how to apply the basic equations to problems. Chapter 6 gives a very thorough account of the application to dynamics, especially to the theorems of Hamilton and Jacobi. The next chapter

returns to the general theory, and deals systematically with Hilbert integrals, which have already been mentioned from time to time in the preceding work, and with the criteria for maxima and minima due to Legendre and Weierstrass. This leads on to Chapter 8, which contains the envelope theorem and Jacobi's necessary condition. The author returns to applications in Chapters 9 and 10, which deal with the brachistochrone and Newton's problem concerning the form of a projectile which offers minimal resistance to the air. Newton's problem offers a surprising difficulty, for its solution has a discontinuity in slope, and this is used to introduce the theory of corner conditions. The next two chapters deal with this theory in detail by the methods of Weierstrass and Erdmann. Chapter 13 is devoted to minimal surfaces of revolution, and Chapter 14 to a further development of Hilbert integrals. The book concludes with an elaborate index. A very short bibliography occurs on p. 10. There are numerous problems, mostly with answers, at the ends of the chapters.

The degree of difficulty of the book appears to be somewhat variable. The discussion of the basic theoretical ideas, especially those originating with the author, appears to assume more mathematical maturity than the discussion of applications, but disclaims "the extremely exacting modern standards of mathematical rigour". The emphasis is on geometry and mechanics rather than on the finer points of mathematical analysis, "without contention that the complete story is told, although it is intended to be included by implication". H. T. H. PIAGGIO

PARASITES OF THE COD

Parasites Animaux de la Morue Atlanto-Arctique.
(*Gadus callarias* L. (= *Morhua* L.))

Par Robert Ph. Dollfus. Pp. 428. (Encyclopédie biologique, Vol. 43.) (Paris: Paul Lechevalier, 1953.) 5,000 francs.

INDEBTED as they already are to Dr. R. P. Dollfus for his considerable contributions to parasitology, all who are interested in parasites, and especially those who are interested in the parasites of fishes, will find this volume a useful addition to their libraries. Explaining that the book is a summary of notes he has made on the subject, Dr. Dollfus remarks that he is not certain that the account he gives of the parasites of the cod is complete, because he has not been able to consult all the literature on this subject, Russian publications having been excluded, and because species of parasites not yet found in the cod may be recorded from this fish in the future. He suggests that he may have cited species which have been incorrectly identified, and explains that he has not been in a position to make sure of the identity of all of the species named.

The volume is, nevertheless, a useful one. It describes about ten species of Protozoa, three species of leeches, two species of monogenetic and about sixteen species of digenetic trematodes, nine species of cestodes, ten or eleven species of nematodes, seven species of Acanthocephala and fourteen species of parasitic Crustacea. Some of the species described are found in the cod wherever this fish occurs; others are found in it only in certain of its habitats; but much remains to be learnt about many of them. The author says that about sixty-nine species have been described as being parasitic in the cod, but that

many of these are doubtful and that probably none of them is specific to the cod. This host always harbours several species at the same time. None of the species recorded from it can be transmitted to man, but one species, namely, the trematode, *Cryptocotyle lingua*, the larval, metacercarial phase of which is encysted in the skin of the cod, can be transmitted to the dog and cat. The adult trematode of this species also occurs in the fox, and it was recently found for the first time in Britain in an otter killed in the suburbs of Edinburgh by Mahfouz A. M. Fahmy (personal communication to the reviewer).

The book, which is issued in paper without boards, is well produced, and its illustrations, all of which are in line, are a valuable feature of it. The bibliography, which the author warns us may not be complete, occupies forty-one pages of small type.

G. LAPAGE

A CONCISE REVIEW OF ANTIBIOTICS

Antibiotics

By F. A. Robinson. Pp. viii+132. (London: Sir Isaac Pitman and Sons, Ltd., 1953.) 15s. net.

IN the field of study of antibiotics, numerous monographs and text-books have been written and the field has become too wide for comprehensive study. The author of this book is to be congratulated in presenting in concise and readable form a broad survey of antibiotics. It should prove invaluable to students and will help the non-specialist in the field to get up to date with general aspects, especially where a chemical bias is desired.

The subject of sulphonamides as an introduction to the book would appear to be unnecessary. The antibiotics in major production are described fully with respect to their production, extraction, spectrum, resistance, pharmacology, mode of action, chemistry and assay; and the lesser-known antibiotics grouped together as mould antibiotics, antibiotics from Actinomyces, and bacterial antibiotics. Such a system allows of easy reference, which, however, might have been improved by bibliographic references in the text. In reviewing the production, extraction and chemistry of the antibiotics, the author has reached a very high standard of presentation. Unfortunately, this standard is not maintained in the pharmacological portions, where some apparently contradictory statements are made: for example, the inhibitory action of penicillin on Gram-negative coliforms is referred to on p. 30, whereas the table of organisms inhibited shows no Gram-negative coliforms; also, streptomycin is used in undulant fever but ineffective in brucellosis. Generalized statements on toxicity rather than lists of LD₅₀'s would make easier reading and not detract from the value of the book.

The author approaches, but does not quite achieve, a consistent system of bacterial nomenclature. Formulae of culture media, excretion statistics and dosage-levels would benefit by tabular or graphical presentation. The details of biological assays have, wisely, been left to the specialized monographs on the subject.

The book can be strongly recommended to degree students and should also prove interesting reading to the general scientist.

A. M. COOK

Population Problems

By Warren S. Thompson. With the assistance of Evangelyn D. Minnis. Fourth edition. (McGraw-Hill Series in Sociology and Anthropology.) Pp. xiii+488. (London: McGraw-Hill Publishing Company, Ltd., 1953.) 52s.

DEMOGRAPHY as a subject of study tends to be neglected in British universities, and it is therefore a tribute to the author that "Population Problems" has now reached its fourth edition since 1930. The general plan of the book remains much the same, yet the author has found it possible not only to include post-war data (much of it up to 1950) but also to incorporate many of the findings of demographic research during the decennium since the publication of the previous edition.

The book is probably best described as a sound introductory text for non-mathematical students. After a rapid survey of population theories from Malthus to Carr-Saunders, the author discusses in turn the determinants of the size of a population—births, deaths and migration. Up to the end of the eighteenth century it was the death-rate which kept in check the growth of population. In modern Western civilization the check is provided by voluntary family limitation. This remarkable transition from uncontrolled mortality to controlled fertility—from the ravages of plague and famine to the planning of parenthood—is discussed widely if not deeply. There are useful chapters on the composition of a population as disclosed by a census, on the decline in the birth-rate, and on class differences in natality and mortality.

The author's attempt to relate factors from medicine, public health, geography, history, economics, psychology and sociology in order to explain the observed facts of demography takes him over too wide a field for thorough discussion of any one topic, while his avoidance of anything that could be called mathematical robs the text of some precision that could have been attained. The last point, however, comes perilously close to criticizing a book which the author never intended to write. H. SILOOCK

Journal of the Institute of Metals

Edited by N. B. Vaughan. Vol. 78, 1950-51. Pp. xxiv+772+80 plates. Vol. 79, 1951. Pp. xxvii+514+61 plates. (London: Institute of Metals, 1951.)

THE Institute of Metals continues to publish papers on a wide range of subjects, and these two volumes of its *Journal*, covering the years 1950-51 and 1951, respectively, contain much work of interest. Vol. 78 contains twenty-one papers, together with a symposium on metallurgical aspects of the cold working of metals, and the Autumn Lecture on communications metallurgy by E. E. Schumacher. Vol. 79 contains the presidential address by Prof. A. J. Murphy, the May Lecture on science in the service of the community by Sir John Anderson (now Lord Waverley), together with twenty-three papers. In the two volumes, the universities, the British Non-Ferrous Metals Research Association and industrial scientists each contribute ten or twelve papers. Six papers are from Australia and serve to emphasize the growth of metallurgical research in this member of the British Commonwealth. Only five papers are published by United Kingdom government laboratories, and the shortage of papers from these sources is to be regretted and may prejudice the recruitment of staff. While many

branches of metallurgy are included, some, such as crystal structure determinations of alloy phases, are absent from these and from the preceding two volumes, and it would be in the interests of metallurgical science if some of this work were attracted to the *Journal*. The two volumes are attractively produced, but the cloth cover of Vol. 78 is too weak for its size. W. HUMPHREY

Lecture Notes on the Use of the Microscope

By R. Barer. Pp. vii+76. (Oxford: Blackwell Scientific Publications, Ltd., 1953.) 6s. net.

THIS little book can be given a whole-hearted recommendation. It is written by one who has made the microscope one of his principal instruments for research, and understands it thoroughly. Essentially practical in treatment, these notes have, however, been written with an eye on modern theoretical work, and they could be read with advantage not only by beginners but also by many others who have occasion to use microscopy in the course of their work.

The author deals mainly with the straightforward operations in visual work and does not enter into the more complicated aspects such as phase-contrast, ultra-violet microscopy, and so on; nor does he deal with photomicrography, though indeed many readers will wish that an introductory chapter on this topic could have been included. A useful section answers a number of the questions which often puzzle the beginner, though it is to be feared that many tantalizing queries will always arise to perplex even the most expert.

The preface asks: "Would it be too much to ask that one afternoon . . . should be spent in learning to understand an instrument which the student may continue to use for the rest of his life . . . ?" Surely the question inadvertently implies a very great reward for two or three hours of concentration. One might perhaps learn to obtain a passable image, but its proper interpretation is quite another matter.

L. C. MARTIN

Wood Chemistry

Second edition. Edited by Louis E. Wise and Edwin C. Jahn. Vol. 1. (American Chemical Society, Monograph Series No. 97.) Pp. vii+688+xxiii. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1952.) 120s. net.

WOOD is still the most widespread industrial material used in the world. It is a source of many of the world's synthetic fibres, of most of its paper and board, and of a large proportion of its fuel. Its constituents and by-products are used in industries as wide apart as the manufacture of solvents and tanning-agents. Moreover, all these industries are based essentially on the chemistry of wood. This indicates the background of the work under review, the first volume of which now published deals with the growth, anatomy and physical properties of wood, its cell wall and extraneous constituents, its surface properties, and its chemical utilization, biological decomposition and chemical analysis.

The two editors are recognized authorities on the subject in the United States, and they are assisted by twenty-two collaborating specialist authors, mostly American, although the chapter on biological decomposition is by the late W. G. Campbell, of the Forest Products Research Laboratory, Princes Risborough. Although the book is largely academic in character,

there is throughout a close correlation between the results of research and their technological applications. The team has, in fact, done its work very well indeed and has produced a comprehensive and up-to-date volume which all interested in the pure and applied chemistry of wood will wish to possess. Unfortunately the high price may prevent a number of them doing so.

JULIUS GRANT

Methods of Statistical Analysis

By Cyril H. Goulden. (Wiley Publications in Statistics.) Second edition. Pp. vii+467. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1952.) 60s. net.

THE first edition of this book was published in 1939. This second edition is almost a new book. After three introductory chapters, it deals with analysis of variance, regression and analysis of covariance. It then proceeds to experimental designs and, in particular, to incomplete block and factorial experiments. There follow chapters on non-orthogonal data, goodness of fit, the discriminant function and probit analysis. A final chapter on quality control has been added, but it seems rather out of key with the rest of the work.

Any scientific worker, whatever his field, who wishes to know the nature and scope of the subject, can scarcely do better than begin with this book by C. H. Goulden. Deriving his inspiration from the work of R. A. Fisher, the author runs very lightly over what J. B. S. Haldane once called anti-hallucination statistics: he arrives at the analysis of variance in Chapter 4 without having discussed standard errors in large sample theory. Some preliminary reading might therefore be recommended to the beginner before he embarks on the book; but once it has been carried out, he can be safely entrusted to Dr. Goulden's concise and careful treatment. This is quite one of the best introductions to modern statistical methods in experimentation that has yet appeared.

M. G. KENDALL

Atomic Transmutation

The Greatest Discovery ever Made; from Memoirs of Prof. Frederick Soddy. By Muriel Howorth. Pp. 134+4 plates. (London: New World Publications, 1953.) 12s. 6d.

IN order to explain the phenomena of radioactivity, Rutherford and Soddy, working together at McGill University, put forward fifty years ago the theory that the atoms of a radioactive substance undergo a process of disintegration which gives rise to the formation of a new atom distinct in physical and chemical properties from its parent. This natural transmutation of the radioactive elements is hailed by the author of this book as "the greatest discovery ever made by man in the history of time". It is her contention, and most of us would agree with her, that the outstanding developments which followed from that initial discovery must be made known to all, both men of science and laymen. However, we may not all agree with the methods she adopts and advocates.

Miss Muriel Howorth is the founder of the Institute of Atomic Information for the Layman, and at the Institute's meeting held on February 28, 1953, the jubilee of Rutherford and Soddy's discovery, Prof. Soddy was invited to talk about those days, "Just fifty years ago". The text of his address, together with the opening proceedings of the meeting, form part of the volume under review. Prof. Soddy

describes in no modest vein the series of events and experiments in which he participated, during the early part of the century. As a kind of introduction to the speaker, Miss Howorth has written these memoirs of Prof. Soddy in which she manages, in the course of what can best be described as a newspaper interview by an over-admiring reporter, to recount mainly in Prof. Soddy's own words his early life and his experimental work up to 1904.

Practical Chromatography

By R. O. Brimley and F. C. Barrett. Pp. 128. (London: Chapman and Hall, Ltd., 1953.) 15s. net.

IN view of the recent spate of books on chromatography, any new book, in order to have any value, must either present an up-to-date review of research on this subject or else must deal with it in such a way that any newcomer to the field should be able to adopt the technique directly to his own problem. In view of this, any short monograph on the subject, such as this one by R. O. Brimley and F. C. Barrett, is of doubtful value. No part of the subject is dealt with at sufficient length, and in addition the proof-reading has been such as to allow a number of glaring mistakes to creep in. For example, a separation showing peaks labelled ammonia, mono-, tri- and di-methylamines is described as showing the separation of fatty acids.

The field of chromatography is now so vast that the main need is for detailed monographs or frequently published critical reviews, and books such as this one fall into neither category.

A. T. JAMES

Woodland Ecology

By Ernest Neal. (The Scholarship Series in Biology.) Pp. xii+107. (London: William Heinemann, Ltd., 1953.) 6s.

THIS is an admirable little book for teachers of biology and for sixth-form students in schools, for whom it is primarily intended. Mr. Ernest Neal has written with the definite aim of helping the student to find out for himself the general pattern of woodland ecology and has achieved something intensely practical that must appeal to keen naturalists of any age.

Limitations of space set a difficult task in dealing adequately with a habitat so complex and so varied, but the task has been successfully tackled by taking the first-hand study of a particular woodland and pointing the way from this. Throughout there is emphasis on integration of details, and the reader is left with an overall picture of the wholeness of the woodland community.

The earlier chapters are concerned with plant ecology, providing the necessary foundation for a proper understanding of the animals and their food relationships. Practical advice is given on methods of finding and collecting animals and on equipment for studying microclimates. The discussion of various types of food chain has much to guide the reader in the fascinating work of tracking down these inter-relationships. The remainder of the book is largely devoted to a consideration of different kinds of adaptations of behaviour and structure which are of value to animals in their competition for food, self-preservation, reproduction and dispersal. There are several good photographs; also included are an appendix giving concrete suggestions for the study of woodland ecology in schools, and a short bibliography.

MAURICE ASHBY

INTERNATIONAL FLAME RADIATION RESEARCH COMMITTEE

NEW LABORATORY

ON April 28, at the Royal Dutch Blast Furnace and Steel Works at IJmuiden, Holland, the laboratory containing the new experimental furnaces of the International Flame Radiation Research Committee was inaugurated. This organization is supported by industry and nationalized industries in Great Britain, France, Holland, Sweden, Belgium and the United States of America, on a basis of free co-operation, in which the various countries contribute not only in funds but also in the loan of engineers and scientists to carry out trials, and of materials and instruments. Until the present time, the main experimental work has been done at IJmuiden on an old furnace not designed specially for the purpose and which was nearing the end of its useful life. The new furnaces just installed have been designed and built specially for studying the radiation and combustion properties of furnace flames, using instruments developed for the purpose. The work will continue to be supplemented by studies on small-scale furnaces in the various countries, but the necessity for near full-scale work has been strongly stressed and the object of the new furnaces is to fill this need.

There are two furnaces, one for oil and gas fuels and the other for pulverized coal, but as yet only the former is operating. The building housing the furnaces includes an instrument room which gives a central and open view of the two furnaces, a specially equipped gas-analysis room, and two auxiliary rooms for pumps, power distribution, stores, etc. Outside

the building there are three liquid-fuel storage tanks. It is intended to provide as soon as possible a combustion air preheater in order to study the effects of raising the entry temperature of the air. Coal preparation plant for the pulverized fuel trials will also be provided in the course of the present year. The experimental station is easily accessible by road and has its own railway siding. The total cost of the completed installation and its services, including all auxiliary equipment, will amount to approximately £60,000.

Furnace for Oil and Gas Firing

Figs. 1 and 2 show side views of this furnace, which has an inner cross-section of 2 m. $\times$ 2 m. and a length of 6.3 m. Since it is intended to work at temperatures up to 1,600°C., sillimanite has been chosen as the refractory material. The complete wall is constructed of one brick of sillimanite, a half-brick of porous sillimanite acting as a high-quality insulating brick, and a half-brick of ordinary insulating brick.

Roof and bottom are of the same composite character as the walls. The whole furnace except the roof is within a light steel casing. Whereas the old furnace rested on the ground, which meant that constant conditions could be obtained only after a week or longer, the new furnace is built clear of the ground, and rests on a set of beams. This may also facilitate measurement of the heat losses through the

Fig. 1. View of the experimental furnace showing vertical slots for radiation measurements

Fig. 2. View of the experimental furnace showing the doors for probe instruments

bottom. Along the sides of the furnaces are eight vertical slots through which measurements of radiation, etc., can be made (Fig. 1).

Special consideration has been given to the construction of the doors closing the openings, in view of the large number of slots and holes in the walls, in order to minimize air in-leakage. The east wall is used for radiation measurements only, the west wall being designed for the insertion, at fixed and known positions, of the various kinds of probe for exploring temperatures, gas composition, soot density, etc. (Fig. 2).

A horizontal beam has been designed on which all the pyrometers can be mounted with their supplies of water and clean air and wiring, the beam being raised up and down by means of two long-screwed spindles mechanically coupled. The water-cooled doors have been made to slide along a pair of water-cooled tubes, one on each side of the slot. In this way, the holes in the doors are always in line with the radiation pyrometers on the beam, and at the same time, reasonable air-tightness has been achieved. On the west wall fixed doors have been provided to cover the slots.

In order to get the maximum results from the measurements, all input variables are under automatic control. Oil can be taken from three different tanks, and preheated as required. Steam (after being superheated in a small gas-fired unit), compressed air, coke-oven gas and oxygen can be taken from the works mains, measured by orifices, and controlled to give a constant flow. Propane, if required, can be taken from a railway tank-car, reduced in pressure and sent to the furnace after being measured.

The combustion air is delivered by fans. When the air-preheater has been installed, air at any temperature up to 750° C. can be supplied.

The average load of the furnace will be roughly 2.5×10^6 kcal. hr.⁻¹, that is, approximately 250 kgm. of oil or 600 m.³ coke-oven gas per hour.

Furnace for Pulverized-Coal Firing

This furnace has been designed along the same lines as the oil and gas furnace, although it has a smaller cross-section (1.5 m. $\times$ 1.5 m.) and is much longer (10 m.), the ratio of length to cross-section being about 7:1 as compared with 3.5:1 for the gas and oil furnace.

The furnace will be constructed with a wall thickness of one and a half bricks, consisting of one brick of high-quality insulation (hot-face) with a special coating against ash attack, backed by a half-brick of ordinary-quality insulation brick. It will be equipped with the same arrangement of slots, doors, moving beam, etc., as the oil and gas furnace.

The floor is to be inclined towards one side, and small doors provided on this side in order to facilitate ash removal.

The average load of the furnace will be of the order of 250 kgm. coal per hour; by means of water-cooled pipes to be introduced through holes in the roof, the thermal load of the furnace can easily be varied between 20 and 70 per cent.

It is also planned to equip this furnace with oil-burning facilities, in order to be able to compare the different types of fuel under exactly the same conditions.

The purpose of the coal preparation plant is to provide the furnace with dry pulverized fuel of widely different characteristics. It must therefore have maximum flexibility, and the separate operations of crushing, drying, milling and weighing are interconnected through storage hoppers. The maximum capacity of the plant will be 500 kgm. coal per hour.

The coal, having been crushed to a size of 3 mm., will be dried in a pneumatic dryer and then pulverized to 90 per cent minus 200 mesh in a ball mill and stored in a 2-ton hopper, whence it will be weighed and deposited at a constant rate into the primary air dust. It is planned to burn coals ranging from anthracite to lignite or brown coal and from 8 to 30 per cent ash content.

Experimental Facilities

These can be divided into different groups. The first group consists of six electronic recorders and one indicator which are of the universal type, with interchangeable ranges and chart-speeds. Some are line recorders, other multipoint recorders. They record all the electrical outputs which are obtained with the furnaces, from radiation and suction pyrometers, thermocouples in walls and roof, heat-flow meters, etc. All leads from both furnaces end in a panel from which any recorder can be connected, by means of flexible leads, with any measuring source.

The second group of facilities, that for gas analysis, is housed in a separate room near the furnace stacks; the equipment in this small laboratory is similar to that of a normal gas-analysis laboratory. Two gas-analysis recorders for carbon dioxide allow rapid surveys to be made of flow patterns in the furnace, or they can be used for recording the carbon dioxide content of the waste gas. There is also a modified Bone and Wheeler gas-analysis apparatus for accurate determination of gas components, special provision being made for the sampling and analysis of carbon soot in the flame. Both the instrument room and the gas-analysis room are kept under a slight air-pressure to minimize the penetration of dust.

The third group consists of instruments set up in a room in the Central Laboratories. These instruments comprise two black-body radiation furnaces, with potentiometers for calibration of radiation pyrometers; thermocouples and heat-flow meters, and further equipment for analysis of gas and carbon soot samples (including an analytical balance). Finally, it should be mentioned that a small water-cooled furnace, which has been in operation for several years in the Research Laboratories of the Royal Dutch Steel Co. at Delft, has been transferred recently to this station. This furnace is a geometrically correct model of the oil- and gas-fired furnace, and has been and will continue to be used for testing scale effects on flame radiation under conditions which can be changed more widely and rapidly than is possible with the full-size furnace. This model furnace will be erected in a few weeks in the pump room, and use will be made of all the facilities for control and experimenting which are already available.

Broadly speaking, two kinds of trials will be carried out on the furnaces. The first, termed performance trials, will measure the overall performance of the furnaces for different conditions including burners, fuels, atomizing agents, inlet temperatures, etc., and it is expected that this will give results leading to immediate improvements in industrial furnace design. The second type of trial, known as combustion mechanism trials, will consist of systematic exploration throughout the furnace of temperatures, gas combustion, soot deposits, etc., with the aim of providing a basis for a theory of flame combustion and radiation.

O. A. SAUNDERS

THE STUDY OF FAST CHEMICAL REACTIONS

FARADAY SOCIETY DISCUSSION AT BIRMINGHAM

ALTHOUGH the word 'fast' is a relative term, the chemist has a fairly clear idea of what he means by a fast reaction: it is one which occurs in a time that is short compared with the times required for ordinary chemical manipulation. Such changes are as numerous and as varied in type as the slower reactions but have one feature in common—that special experimental techniques are required for their investigation. These techniques were the subject of the Faraday Society Discussion held in the Chemistry Department of the University of Birmingham during April 7–9. The president of the Society, Prof. R. G. W. Norrish, was in the chair, and the meeting was attended by 230 people, about thirty of whom were from overseas. Introductory papers to the two sections on gas- and liquid-phase reactions, respectively, were given by Prof. H. W. Melville and Mr. R. P. Bell. There were contributions from physicists, chemists and biologists, and a valuable feature of the Discussion was that it brought to wider notice a number of techniques which, though potentially of general application, have been developed and used almost exclusively for one field of study. The diversity of methods described was no less than the variety of fast reactions to which they have been applied. The half-times of these reactions cover the range from several seconds to 10^{-11} sec., and nearly every conceivable physical property was considered as a means of following such a change.

When the half-time of reaction is less than a few seconds, two difficulties arise in its experimental investigation: first, it is necessary to initiate the change in a time which is short compared with the time of reaction, and secondly, a means of following the reaction must be found which is of sufficient sensitivity and which has a short response-time. Alternatively, instead of measuring a parameter directly as a function of time, the rate of the rapid reaction may be arrived at by introducing the time parameter in the form of a competitive process such as diffusion or another reaction of known rate. The latter method has been most widely used and was represented by a number of contributions to this Discussion, but there was a sign that the direct methods of approach are being more widely applied than in the past.

An obvious way of initiating a reaction is by mixing, and when this method is used the time of mixing is the limiting factor which determines the fastest reaction that can be studied. It has been mainly applied to liquid systems and is suitable for reactions with half-times greater than about 1 msec. The original continuous flow method, developed by Hartridge and Roughton thirty years ago, which has been of such great utility in the study of biological systems (F. J. W. Roughton), has now taken a variety of forms. The two liquids may be injected from separate containers into the mixing vessel and then studied by photoelectric (K. Dalkiel) or thermal (L. Pearson, B. R. W. Pinson and F. J. W. Roughton) methods as they flow along an observation tube at a known rate. In the stopped-flow technique the reactants can be made to impinge on a light piston which suddenly arrests the flow (Gibson). Such

apparatuses have been made semi-automatic and can be accurately controlled by thermostat (E. F. Caldin and F. W. Trowse), and by using regenerative flow (B. Chance and V. Legallais) the performance may be increased by ten- to a hundred-fold without the expenditure of additional solution. Chance has given detailed consideration to the design criterion for optimum performance of flow systems. Rapid quenching, which is frequently a useful technique in slower reactions, can also be applied to fast reactions in flow systems (B. R. W. Pinnent). A third modification is the capacity flow method (K. G. Denbigh and F. M. Page) where the well-mixed reactants are allowed to reach a steady state in a vessel. This is unsuitable for half-times less than about one second, but covers a time range where the continuous flow methods are less convenient. A related method is the use of the thermal maximum attained in an exothermic reaction which is losing heat to the surroundings at a known rate (R. P. Bell, V. Gold, J. Hilton and M. H. Rand). It does not involve a steady state, but measurement is made during a momentary stationary condition which is easy to observe. The method of mixing of reactants may also be applied to gas reactions, though it becomes difficult to study half-lives shorter than 0.1 sec., not only because of the rate of mixing but also because the requirement of constant temperature becomes increasingly disturbed by the heat liberated from the reaction (H. S. Johnston). This is less serious in liquid systems owing to the greater thermal capacity.

Photochemical initiation has been widely used in the study of fast reactions, the rate of the fast reaction usually being obtained by a steady-state treatment, involving another process of known rate. A new type of steady-state measurement, in a gaseous photochemical system, is to observe the temperature rise, which may be of the order of 0.1 deg. C., by means of a fine platinum wire placed a known distance from a plane window to which it is losing heat (A. B. Callear and J. C. Robb). It has the advantage that a rate measurement can be made in about one second, so that very little reaction has taken place. Photochemical methods may also be used to initiate a reaction for subsequent study by direct methods. In order to obtain an observable change, flash photolysis is used, and by this means the intermediate free radicals may be prepared in a fraction of a millisecond at a concentration high enough for spectroscopic observation (R. G. W. Norrish and G. Porter). The method has now been applied to reactions in solution, in particular to the detection and study of the triplet states of molecules which are found to have half-lives between 10^{-8} sec. and 10^{-9} sec. in fluid solvents (G. Porter and M. W. Windsor). Here we have a new type of fast reaction, which is of very general occurrence and which exhibits many unusual features.

Another common method of initiating a reaction is to raise the temperature of the reactants. When this is done by admitting the mixture to a heated vessel, about one second elapses before a uniform temperature is attained, and the method is not therefore applicable, in this form, to fast reactions. The temperature of a gas may be raised by as much as 1,000 deg. C. in a very short time, however, by the use of a shock wave. A diaphragm, separating a gas at high pressure from the reaction mixture at a lower pressure, is broken, and after passage of the shock front the reaction is followed photoelectrically with a time resolution of about 5 μ sec. (D. Britton, N.

Davidson and G. Schott). Here one is measuring the relaxation time which elapses before the system adjusts itself to the new equilibrium conditions, and a variety of other techniques, applicable to the study of very fast reactions, operate on the same principle. The gas may be made to flow slowly and isentropically through a nozzle and then be rapidly compressed, in a few microseconds, in front of an obstacle. The observed difference between original pressure and stagnation pressure is then directly proportional to the entropy gained in the latter compression (S. H. Bauer and M. R. Gustavson). Relaxation techniques may also be used for the study of ionic reactions in solution where the half-times may be less than 10^{-9} sec. A disturbance of the electrolytic dissociation equilibrium may be effected, by rapid variation of pressure (sound absorption), electrical field density or temperature, and the change may be introduced periodically by a single impulse or in the form of a rectangular step. All these cases are accessible to mathematical treatment (M. Eigen). The relaxation of the second Wien effect in the presence of radio-frequency fields may be used by measuring power loss, or apparent ohmic resistance, at various frequencies (R. G. Pearson).

An unconventional method of initiating reaction is by mechanical activation of one of the reactants. This may be brought about by a rapidly rotating blade, the molecules being flung from the tip of the blade with a velocity equivalent to an energy of 10 kcal./mole (T. H. Bull and P. B. Moon). The method requires further development but has interesting possibilities.

Apart from the method of initiation, the principal problem of fast reaction studies is to find a suitable means of following the change. The main difficulties here are twofold: when the response time of a detector is increased, its sensitivity is automatically decreased; secondly, fast reactions are always accompanied by temperature changes, and indeed in the most rapid changes the process occurs virtually adiabatically. It is therefore essential to use a physical quantity which is relatively insensitive to temperature, and these are not numerous. By far the most useful is light absorption, which can be conveniently followed by photoelectric methods or by flash spectroscopy. A second approach, which has been used by a number of authors, is to measure the temperature rise itself. Several methods of doing this have already been mentioned, and a further example is the measurement of the temperature profile in the reaction zone when one reactant is introduced to the other through a jet (D. Garvin, V. P. Guinn and G. B. Kistiakowsky). This is a generalization of the 'highly dilute flame' technique of Polanyi and is applicable to reactions other than those which show resonance absorption or emission, or give solid deposits.

Dielectric constant and refractive index are very dependent on temperature, but may nevertheless be used as sensitive methods of following rapid chemical change. It is usually found that the temperature effect is the greater, and correction is made for the effect due to chemical change. By interferometry, which can be carried out rapidly using photoelectric techniques, temperature changes of 2×10^{-4} deg. C. can be followed (G. M. Burnett, P. J. Deas and H. W. Melville). Nuclear magnetic resonance spectroscopy is a method which has not hitherto been applied to fast reactions and which appears promising. The details of the resonance spectrum

are strongly modified when the nucleus in question is suffering a sufficiently rapid change in chemical environment (R. A. Ogg).

Conductimetric methods, using high-frequency oscillators, are useful for following ionizable systems in solution. At megacycle frequencies it is not necessary to have electrodes in contact with the solution and more rapid recording is possible (P. J. Elving). Changes in ion concentration during a fast reaction can be measured by using a rotating platinum-wire electrode in conjunction with an automatic recording polarograph (I. M. Kolthoff and W. L. Reynolds). One of the oldest electrochemical methods, which has seldom been applied, is 'voltammetry at constant current' (P. Delahay). It has certain advantages over polarography, but both methods are limited by the difficulties of theoretical analysis of reactions of higher order than the first.

The older methods of chemical kinetics, where the velocities of very fast reactions are inferred from a leisurely analysis of the final products, will continue to play an important part, especially as new tools, such as isotope-enriched molecules, become available (R. A. Ogg and W. T. Sutphen). With this wealth of experimental method the often-encountered statement that a reaction was 'too fast to follow' should disappear from the literature. The only danger appears to be the one mentioned by Prof. Melville in his introductory remarks, that one may become so impressed by the gadgetry that one loses sight of the purpose for which the gadget was designed. The final criterion by which any experimental technique must eventually be judged is the originality and reliability of the information which it provides.

GEORGE PORTER

MARINE BIOLOGY IN NATAL

By ROBERT CLARKE

National Institute of Oceanography, Wormley, Surrey

LIKE many other countries since the Second World War, South Africa now faces the problem of nourishing a rapidly increasing population. Although she has vast tablelands, their fertility is menaced by a widespread soil erosion, and it is natural that South Africa should turn for her protein supplies more and more to the resources of the sea. On her west coast the cold, productive Benguela Current maintains extensive fisheries for pilchard, hake and snook, and to the south is the flatfish ground of the Agulhas Bank. The demands of research and development in these areas may be expected, in the future as in past years, to preoccupy the attention of the Division of Fisheries, Cape Town, whose research ships have already done valuable work on the west and south coasts. On the other hand, the resources of the east coast remain practically unknown: the seas between Mozambique and East London, except for certain excellent studies of the littoral fauna, have scarcely been explored by fishery biologists or oceanographers. It is therefore most encouraging to learn that this neglect is shortly to be remedied by the building of a new and extensive marine research station at Durban in the province of Natal. Funds for the project are being subscribed by the recently founded South African Association for Marine Biological Research*.

* "South African Association for Marine Biological Research" (Central Press, Durban, 1953).

What purely faunistic surprises may await the investigator are suggested by the discovery of the first ctenophore off East London in 1938 and, in the past year or two, of other specimens in the Mozambique Channel. Apart from the ctenophore, however, the diversity and fascination of the problems awaiting solution in this region, contrasted with the scant attention it has received, greatly impressed me during the voyage of the Royal Research Ship *William Scoresby* in 1950 when, in the midst of a whale-marking cruise, the ship conducted a limited amount of oceanographical work and experimental fishing across the Mozambique Channel and in the Agulhas Current opposite East London. Because the area is extensive, the work of other expeditions, though valuable, has been no less incomplete. The R.R.S. *Discovery II* has worked some oceanographical stations up the Mozambique Channel and in the Agulhas Current off Durban, including a few extending eastward into the West Indian Ocean. On the coast banks some experimental trawling has been done by the *Africana* from the south towards Durban. The abyssal fauna of the oceanic region remained unexplored until 1951 when the *Galathea*, by several successful hauls in latitudes around Durban and in the Madagascar Deep, indicated the scope for work of this kind. These fragmentary investigations are no more than pointers for an oceanographical survey, complete in its widest sense, which the waters east of Africa deserve and which offer a fund of problems to the South African Association for Marine Biological Research.

A great deal has yet to be learned about the hydrology of the south-east African region. To the south of Madagascar the Mozambique Current is augmented by another arm of the Trade Wind Drift and flows southward, following the line of the African coast, as the warm, swift Agulhas Current. Between the main current and the coast there is a minor stream of cold water, of variable extent and velocity, which sets to the northward. So far as I am aware, nobody has yet investigated the origins of this counter-current, or its effects on the organic productivity of the coastal area. Hydrological survey of the counter-current may also suggest means of controlling the banks of shifting sand which are caused by this current and which at present are a major problem to the engineers of Durban harbour. One of the most interesting yet least understood things about the main Agulhas Current is the likely presence of marginal upwelling. This phenomenon is something quite distinct from the counter-current and is believed to occur when the main current is accelerated, as by strong winds, so that the denser water (which in the southern hemisphere always flows on the right-hand side of a current system) is brought to the surface on the inshore side of the current by hydrodynamic forces. Such marginal upwelling of nutrient-rich cold water, adjacent to or over a coast bank, may be sufficient to increase the productivity of waters available for fishing.

The most obvious biological effect of the Agulhas Current is the environmental one regarding the physical and chemical parameters it establishes for the fauna, including the economically important fish fauna. Temperature is most important. The current in the Mozambique Channel has a warm-water fauna of Indo-Pacific character. As the current moves southward it becomes cooler, approaching the region of the West Wind Drift off the extreme south coast of Africa. So it happens that the sea off the coast

of Natal is a region of transition where Indo-Pacific forms mingle with elements of the temperate Cape fauna. All authorities are agreed that the Natal area is very rich in species, and as a transitional region it is specially attractive to the taxonomist and ecologist and to the scientist interested in problems of evolution. Prof. J. L. B. Smith has studied intensively, though he would not wish to say exhaustively, the littoral fishes of Natal, and Prof. T. A. Stephenson and his colleagues have examined the ecology of the littoral invertebrates; but less attention has so far been paid to transitional problems in the neritic and oceanic faunas which include the actual or potential species of major economic importance. Thus the Cape hake sometimes extends to the Natal region and, especially in winter, may even appear in great shoals. Practically nothing is at present known of this seasonal invasion. The Cape snoek (*Thyrsites*) does not penetrate into Natal waters, where the local 'snoek' is a species of *Scomberomorus*; but the possibility of exploiting *Scomberomorus* on a large scale might be investigated.

Among the oceanic fishes of the current, the giant scomberoids, like the tunny, may be sufficiently abundant to allow a regular fishery. The tunny at the present time is everywhere becoming increasingly popular as a food fish. A survey of the myriad shoals of flying fish would not only be important in regard to the distribution and possible migrations of the tunny and albacore which prey on them, but also would be important in itself, for flying fish are excellent eating and in California and Barbados they are fished on a commercial scale.

Any wide survey may discover new fishing banks. The search far afield need not be disregarded. Off the south coast of Madagascar lies the Star Bank, where I have myself hauled the trawl and been impressed by the wealth of fauna: the Star Bank certainly deserves a fishing survey. On the coast banks of Natal itself there is an abundance of sharks. The shark fishery which once existed at Durban might be revived if attention could be given to such problems as extracting the liver oil, refrigerating, salting and packaging the meat, preparing meat meal, shark leather and shagreen, and marketing these products.

Technical problems of this kind would doubtless be included in the scope of the new station. Its aquarium also (which will be a major feature of the building) could be used not only for purely biological studies but also for such technical investigations as the development of electric fishing methods.

There may be several potential inshore fisheries awaiting the results of survey and research. In South Africa eels are only found in rivers flowing east to the Indian Ocean, and the story of their spawning migration has still to be told. Pearl oysters occur in the Natal area and there are possibilities for oyster-farming on a commercial scale. Some extremely interesting surveys by Prof. J. H. Day and his colleagues have indicated the abundance of prawns and fish in certain estuaries on the Natal coast. There may be opportunities here for farming of a kind which has been very successful in many parts of Asia. Furthermore, the abundant pensid prawns (which in Natal take the place of the Cape crawfish) are thought to be migratory, and the tracing of these migrations may lead to an offshore prawn fishery like that discovered in deep water by the late Prof. Johan Hjort and made into a considerable industry in Norwegian seas.

Although territorial problems may need to be settled, an oceanographical survey which includes the Madagascar seas might find the search for guano worth while: it is possible that on such islands as Europa Island there are exploitable deposits of seabird guano.

Whaling is conducted from the Bluff at Durban, so the new marine station may expect to have excellent opportunities for research on whales and the special problems of the whaling industry. Here is a field for investigations of great economic importance, for Durban takes mostly humpback and sperm whales, the life-histories of which are still imperfectly known. Apart from two seasons work by the former Discovery Committee's staff in 1926 and 1930, and some whale marking by the *William Scoresby* in 1950, there seems to have been no research on these stocks in their migrations along the waters east of Africa.

By establishing the new marine station in a sub-tropical area, the South African Marine Biological Association reflects that interest in the possible resources of warm seas which since the Second World War has led to the setting up of research centres on several tropical seaboard of the British Commonwealth and the Colonies. These are government institutions, but it seems that most of the funds for the Durban Station are being raised from the subscriptions of private citizens. We wish the Association well.

PURIFIED CASEIN FOR NUTRITIONAL RESEARCH

By ALICE M. COPPING

Queen Elizabeth College, University of London

NUTRITIONAL experiments for the past thirty years have progressively emphasized the need for a source of protein which is pure and of high biological value, and it has come to be realized that casein is the most suitable protein for experiments with such small animals as rats, mice and chicks and such large animals as pigs. Latterly, it has been used also in experiments with insects and in microbiological studies. Casein is the principal but not the only protein providing the food of the growing calf, and its high biological value has been demonstrated by Karl Thomas¹, by McCollum², by Chick and co-workers³ and by many others using various techniques. It contains all the essential amino-acids though the relative amount of the sulphur amino-acids is rather low, so that experimental diets are more certain to be satisfactory when they contain about 20 per cent of casein than if they have less than 10 per cent. The low content of sulphur amino-acids has to be remembered in choosing the methods for purifying casein, care being needed to avoid damage to them.

By 1920, when Coward⁴ reported the occurrence of a growth factor, different from the then recognized vitamins, in light white casein it was known that purification by washing and extraction was essential to give a casein that could be used satisfactorily in diets for studying vitamin A and the B vitamins. At this point it is relevant to give some description of the types of casein products available for biological studies. Light white casein, to which reference is made above, is not a true casein but a caseinate

formed by treatment of casein with dilute alkali, as sodium hydroxide or calcium hydroxide. High-grade caseins for animal diets are generally acid caseins and not caseins produced by rennin precipitation. The acid caseins may be prepared by natural lactic acid precipitation produced by bacterial action in sour milk or by the addition of hydrochloric or other acids. Acid caseins contain some lipid substances which can be removed by alcohol extraction in order to decrease the content of fat-soluble vitamins. The alcohol extraction process removes only part of the vitamin B complex, and further washing with sodium chloride solution to remove riboflavin and with acetic acid for other B vitamins is necessary to give a 'vitamin-free' product. It is now known that these processes should be undertaken during manufacture preferably before the curd has been dried. In the final processing and drying, careful attention to temperature and other conditions is required to give a product that is substantially free of all vitamins and that, at the same time, retains its high biological value.

Before purified caseins became commercially available, research workers purified their own caseins. At the Lister Institute a casein suitable for diets free from vitamin A was for many years prepared by heating light white casein with constant aeration obtained by frequent raking of the material in shallow trays in an electric oven at 110° C. The heated casein was satisfactory for vitamin A studies, but not for work with the vitamin B complex. For the latter purpose the caseinate was subjected in the laboratory to precipitation by dilute acetic acid, followed by washing and extraction with 70 per cent alcohol¹. The process was very laborious, and preparation of solvent-extracted casein was soon taken over by commercial suppliers, and extracted caseins could then be purchased. From 1930, commercial developments in Great Britain and in the United States provided purified caseins of various grades for research laboratories. The most satisfactory products were obtained by precipitation of casein at its isoelectric point with subsequent extraction and washing. Unless all processes were fully controlled, the physical properties of the products might vary and the caseins became difficult to incorporate into diets and media. As identification of the various members of the vitamin B complex progressed, it seemed probable that solvent extraction denatured the product in some way which affected the growth of rats on highly purified diets. The recent work of Hartman, Cary and colleagues², of the U.S. Department of Agriculture, has amply demonstrated the presence of components of the so-called 'animal protein factor' in casein which has not been subjected to washing or extraction.

Until the outbreak of the Second World War in 1939, caseins of guaranteed purity were prepared in Great Britain by Glaxo Laboratories, Ltd. Their products included an 'Ashless Extracted' casein suitable for studies of vitamin A and vitamin D, a 'Riboflavin-Free' casein suitable for studies of the vitamin B complex, and other grades of casein required for many types of experimental diets. War-time difficulties caused a cessation of supplies, and by the end of the War all workers in Britain who were concerned with biological and microbiological studies requiring purified casein were faced with an urgent problem of supplies. For a time a highly purified casein was available from the United States. It was guaranteed to be free from water-soluble

vitamins B, C and G (riboflavin) and fat-soluble vitamins A and B. It contained as a typical analysis:

N	15.40 per cent
Casein (N x 6.38)	98.25 "
Ash	0.85 "
Moisture not above	5 "

It was an excellent preparation, but was too costly in dollars to be long available; and strenuous efforts in Britain and in other milk-producing countries of the Commonwealth, particularly in New Zealand, finally led to an arrangement by which Messrs. Genatosan, Ltd., a member of the Fison group of companies, undertook to prepare a purified casein by a process of successive treatments with dilute acetic acid and sodium chloride. Without use of other solvents which, rightly or wrongly, was considered undesirable, it was impossible to obtain a product entirely free from vitamins of the B-complex, but a suitable specification was agreed upon and the label of a recent batch of Genatosan low-vitamin casein reads as follows:

Appearance	Cream coloured powder
Loss at 100° C.	Not more than 5 per cent
Protein (by nitrogen)	Not less than 90 per cent
Ash	Not greater than 1 per cent
Amino hydrochloride	Not greater than 1 part per million
Riboflavin	Not greater than 0.25 part per million
Nicotinic acid	Not greater than 1 part per million
Pantothenic acid	Not greater than 0.75 part per million

Moreover, a special analysis of every batch of casein can be obtained on application to Genatosan Laboratory. The provision of such material is an invaluable service for those who require exact knowledge of the vitamin and protein content of diets and media, and involves great labour and expense which inevitably makes the cost of the purified casein high. However, in view of the need for precise control of diets in nutritional research and especially in experimental studies of the factors of the B complex, the outlay must be accepted.

In Queen Elizabeth College, for example, we are carrying out studies of the nature of growth factors required by rats and of the specific effects of purified diets on their blood picture. The low-vitamin casein of Genatosan, Ltd., is proving a satisfactory substitute for caseins previously used, and during the past five years has provided a constant source of protein yielding consistent biological responses. A test of its adequacy has been carried out by measuring the growth response over relatively long periods of rats receiving highly purified diets complete so far as present knowledge of growth factors is concerned. Zucker and colleagues³ showed that inadequacy of dietary protein was indicated by failure to attain a straight line when the logarithm of the weight increase was plotted against the reciprocal of the time. The use of this method was shown by Copping, Crowe and Pond⁴ to be applicable to testing the nutritive value of a number of different caseins. Further studies⁵ on the Genatosan product have produced growth curves which are not significantly different from those reported in the earlier paper. In experiments involving deprivation of a single member of the vitamin B complex, such as pyridoxine or pantothenic acid, very rapid depletion of rats has occurred, with development of characteristic signs of the deficiency.

This laboratory is not alone in making such studies. It is only necessary to look at the nutritional literature currently appearing in Great Britain to realize what a serious problem it would be if any breakdown in

the supply of purified casein occurred at the present time, when many laboratories are deeply involved in nutritional studies that depend basically on the use of balanced purified diets.

OBITUARIES

Prof. Selig Brodetaky

SELIG BRODETAKY was a man of distinguished and diversified gifts. His position as Senior Wrangler at Cambridge in 1908 showed the mathematical promise that was in him as a young man, and he later specialized in applied mathematics, particularly in aerodynamics, and published much in that field. He was a brilliant expositor and teacher on mathematical subjects, never failing to hold spellbound his hearers whether students of pure and applied science or people of a more general character. He was much sought after as a lecturer on astronomy, revealing the wonders of the heavens to popular audiences, and in this he carried on the tradition of Sir Robert Ball, the Irish astronomer, whose pupil he was. He wrote several text-books on mathematical subjects, mechanical principles of the aeroplane, nomography, etc.; his biography of Sir Isaac Newton was much appreciated by a wide variety of readers.

To regard Brodetaky, however, solely as a scientific man would be to convey little idea of the wider scope of his talents. In addition to mathematics, his main interests were Zionism and the cultivation of the Hebrew language as a medium of ordinary intercourse among Jews. In pursuance of his dream to see the Jews established in the traditional land of their forebears, he was indefatigable in his labours, and travelled by land, sea and air over all the four continents, lecturing and expounding his views and aspirations for the Jewish people. There would seem little doubt that these years of strain and over-exertion led to that ultimate exhaustion which lay at the root of his final illness. During these journeyings the world over, Brodetaky established many contacts with numerous nations and personalities. He did not merely confine himself to Judaism in his wanderings, for he noted intensively systems of government, social manners of life, school and university education, etc. The result of these wide experiences was that his contributions to debates on educational and academic policy and development on the wide scale were recognized as particularly valuable.

Selig Brodetaky was born in Russia, near Odessa, into a poor but cultured home. His father was the traditional Jew, mighty in the Scriptures and well versed in the Talmud. Brodetaky used to relate that he was born at midnight and hence could not say which of two dates was his birthday. On account of the ever-recurrent pogroms against the Jews in Russia, his father decided to leave that country and

to settle with his family in England. He migrated to the East End of London, which according to the scanty information he could gather was about the only place in England where foreign Jews could hope to get a footing. He arrived entirely ignorant of the English language or of English customs, but by grim determination he succeeded in getting a foothold. He then summoned his wife and four small children to join him, and she had to cross Europe unaided with a baby girl to be carried in her arms. Brodetaky as a child of four years of age remembers them hiding in a hen-coop until a kindly army officer signalled to them after nightfall that now was the time to cross the frontier; while crossing, the baby in arms started to cry, but her mother pushed her shawl into the child's mouth. Their struggle for existence in London during their first years was rigorous, for they lived in a block of buildings surrounding a courtyard with twenty families to one pump situated down in the area. All the ultimately large family had to toil hard for daily bread from their childhood days, but they made good in the end.

Brodetaky was educated at the Central Foundation School, London, and by the aid of scholarships he entered Trinity College, Cambridge. After being placed Senior Wrangler in Part I of the Mathematical Tripos, he won a good position in Part II of the Tripos and thereafter studied on the Continent of Europe at the University of Leipzig. He joined the mathematical staff of the University of Bristol, whence he went to Leeds in 1920, becoming professor of applied mathematics four years later. He left Leeds in 1948 on his appointment as president of the Hebrew University at Jerusalem, but ill-health supervened, and he had to resign and come back into retirement in England. He died in London on May 18 at the age of sixty-six and is survived by his widow, Mania Berenbhum, of Bialystok, and a son and daughter.

In temperament, Brodetaky was a very charming man, most obliging in co-operating with his colleagues and ever ready to help a student in financial or other difficulties. He leaves a very pleasant memory behind him.

WILLIAM P. MILNE

Prof. F. LI. Hopwood

THE sudden death on May 2 of Frank Lloyd Hopwood is a heavy and unexpected blow to his many friends all over the world and leaves a conspicuous gap among the pioneers of medical physics. It seems impossible that this large, impressive, and yet so friendly figure has passed from our scene and will no longer encourage, or perhaps gently reprove, the actions of those individuals, single or corporate, working in his field.

Hopwood's scientific interests were wide—perhaps even too wide, yet befitting a rapidly growing borderline subject where the possibilities of immediate or ultimate application of physics to human welfare so attracted him. First as demonstrator, and later as professor of physics in the Medical College of St. Bartholomew's Hospital, London, he was active early in the radiological field; first in the application of the then new Coolidge tube and high-tension techniques and their possibilities of use in procuring more penetrating and therefore more effective X-radiations in the treatment of cancer, as well as in the more physical studies of radiation dosimetry. Later, as a member of the International Commission on Radiological Units, he played an important part in the

discussions leading to the present definition of the unit of dose. It is also to be remembered that in collaboration with such pioneers as Strangeways, Canti and Donaldson at 'Barts', he was responsible for the physical aspects of some of the earliest work using tissue cultures in the study of the effects of ionizing radiations on living cells.

Long an authority in the physical aspects of the use of radium in the treatment of disease, he realized very quickly the importance to medicine of the discovery of artificial radioactivity, and particularly its production by neutrons, so that it is no accident that the important Skillard-Chalmers type of reaction was brought to light by those workers in his department. The physico-chemical effects of neutron irradiation, particularly in respect of biological action, early interested him, as may be seen from the Silvanus Thompson Memorial Lecture delivered by him to the Institute of Radiology.

His other main scientific interest lay in the field of sound, audible or supersonic. Undoubtedly stimulated by his work during the First World War with the Admiralty Research Station at Harwich when he worked on the detection of underwater sound, Hopwood built a supersonic generator and showed the

destructive power of this 'radiation' on such simple organisms as *Nitella* and carried out many experiments on the subject. This interest in sound persisted to the end of his life and, characteristically enough, the last conversation I had with him a week or two before his death was filled by an account, delivered with boyish enthusiasm and much dexterous manual demonstration, of experiments he had been carrying out at home on the strange and fascinating things to be seen in a kitchen sink in jets of water impinging on perforated metal.

One other aspect of Hopwood's work must be mentioned. He was perhaps at his best as a teacher. Lucid, thorough, impressive and enthusiastic, even first-year medical students fell under his spell, as well they might, for many of them 'off stage' had known his fatherly interest in them when as dean he had at once admonished and shielded them in their misdeeds.

Hopwood was called on to undertake much committee work, and mention must be made of the help he rendered on their governing bodies to the Physical Society, the Institute of Radiology (of which he was president) and, among many others, to the British Empire Cancer Campaign. W. V. MAYNEORD

NEWS and VIEWS

The Queen's Birthday Honours List

THE Queen's Birthday Honours List includes the names of the following scientific men and others associated with scientific work:

Baronet: Sir Russell Brain, president of the Royal College of Physicians of London.

Knights: Dr. A. Chester Beatty, vice-patron (formerly president) of the Royal Cancer Hospital, London; Dr. Gavin R. de Beer, director of the British Museum (Natural History); Dr. Ian Clunies-Ross, chairman of the Commonwealth Scientific and Industrial Research Organization, Australia; Dr. Arnold A. Hall, director of the Royal Aircraft Establishment, Farnborough; Dr. Alexander P. Murphy, president of the Royal Australian College of Physicians; Prof. Francis E. Simon, professor of thermodynamics, University of Oxford; Dr. Thomas M. Taylor, principal and vice-chancellor of the University of Aberdeen; Prof. Alexander R. Todd, professor of organic chemistry, University of Cambridge, and chairman of the Advisory Council on Scientific Policy.

C.M.G.: Ivor Bowen, lately head of the United Kingdom Ministry of Supply Staff, Australia, now principal director of equipment research and development (air), Ministry of Supply; R. J. Simmons, adviser on animal health to the Secretary of State for the Colonies; Dr. A. Topping, dean of the London School of Hygiene and Tropical Medicine.

C.B.E.: W. G. Alexander, deputy secretary, Agricultural Research Council; G. H. Bacon, lately director of agriculture, now agricultural adviser to the Sudan Government; H. Davis, chief pharmacist, Ministry of Health; Dr. G. E. R. Deacon, director of the National Institute of Oceanography, Wormley, Surrey; Dr. M. S. Jones, director of the Social Rehabilitation Unit, Belmont Hospital, Sutton, Surrey; Dr. W. Idris Jones, director-general of research, National Coal Board; R. S. Marshall, inspector-general of Animal Health Services, Nigeria; Prof. L. H. Martin, professor of physics in the Univer-

sity of Melbourne; K. T. Parker, keeper of the Ashmolean Museum, University of Oxford; V. A. Pask, chief engineer, Headquarters of the British Electricity Authority; H. G. Raggatt, secretary of the Department of National Development, Australia; Prof. L. Rosenhead, professor of applied mathematics, University of Liverpool; D. R. Rosevear, inspector-general of forests, Nigeria; A. E. Russell, director and chief designer, Bristol Aeroplane Co., Ltd.; H. L. Shrimpton, chief livestock husbandry advisory officer, National Agricultural Advisory Service; H. Tongue, chief engineer, Atomic Energy Research Establishment, Harwell, Berks; H. L. Verry, assistant secretary, Department of Scientific and Industrial Research; J. R. Whinfield, of Imperial Chemical Industries, Ltd., for services in the invention of 'Terylene'; I. D. Wratten, lately president of the Royal Photographic Society of Great Britain; Prof. C. M. Yonge, regius professor of zoology, University of Glasgow.

I.S.O.: J. D. Broatch, deputy director of agriculture (cocoa industry), Gold Coast; G. A. Elliott, director of surveys, British Honduras.

Mathematics at Reading: Prof. E. H. Neville

IN July, Prof. E. H. Neville retires from the chair of mathematics at the University of Reading, which he has held since 1919. His publications cover a wide field of mathematics: in 1922 his "Prolegomena to Analytical Geometry" gave a consistent logical basis to the concepts of complex space and ideal space, and in 1944 a skilful combination of technique and logic in his "Jacobian Elliptic Functions" developed beauty and order in a domain which had often seemed overgrown with an amorphous welter of formulae. Prof. Neville was president of Section A. (Mathematics and Physics) of the British Association in 1950, and his presidential address, "Mathematical Notation", is a penetrating essay towards the study of the influence of symbolism on the development of mathematical thought. He also served for many

years on the Tables Committee of the British Association, now the Tables Committee of the Royal Society, and his own table, "Farey Series of Order 1025", was the first volume of the Royal Society series. The belief that the professional mathematician need not concern himself with pedagogical problems has never been accepted by Prof. Neville, and he has taken a leading part in the work of the Mathematical Association in the improvement of the teaching of mathematics. In particular, the Association's reports on the teaching of geometry in schools owe much of their power and authority to Neville's committee work. He was librarian to the Association during 1923-53, and president in 1934. Between the two World Wars, Prof. Neville was the British representative on the Central Committee of the International Commission on the Teaching of Mathematics.

Dr. R. Rado

PROF. NEVILLE will be succeeded by Dr. Richard Rado, at present reader in mathematics in King's College, London. Dr. Rado, who is forty-eight and Hungarian born, studied first at the Universities of Berlin and Göttingen, taking his Dr.phil. (Berlin) in 1933, before going to Cambridge to study under Prof. G. H. Hardy, where he took his Ph.D. in 1935. During 1936-47 he was on the staff of the Mathematics Department at Sheffield, becoming a naturalized British subject in 1940, and in 1947 he was appointed to his present post in London. He is at present secretary to the London Mathematical Society, having been a member of the Council since 1948. Dr. Rado has published in all nearly fifty papers, many of them very substantial, in various learned journals. His main interest has been in general problems of combinatorial analysis, and especially in results of the type: "Every random system of some specified class contains a highly regular sub-system of some other specified class", such problems arising in number theory and in algebra, and being in any event worth studying for their own sake. His work also includes researches on graphs (one-dimensional topology), affine invariants of convex bodies, inequalities (he assisted in the preparation of the book "Inequalities" by Hardy, Littlewood and Polya), and transfinite numbers, where properties are sought which reveal differences of structure and behaviour of such numbers. The high distinction of his researches, the authority of his scholarship and his well-known brilliance as a lecturer have all contributed to the powerful influence which he has latterly exerted on the development of mathematics, particularly in London.

Biological Division of the Wellcome Research Laboratories: Colonel H. W. Mulligan, C.M.G.

COLONEL H. W. MULLIGAN assumes on September 1 the appointment of head of the Biological Division, The Wellcome Research Laboratories, Beckenham, previously held, in association with other duties, by Dr. J. W. Trevan, who retired in August 1953. After graduating from the University of Aberdeen in 1923, Colonel Mulligan served in the Indian Medical Service until its disbandment in 1947. He was posted to its Medical Research Department in 1928 and remained in this branch except for three years on active service during the Second World War, when he ultimately became consultant malariologist, Persia and Iraq Command. Among the appointments he held in India were those of director of the Pasteur Institute, Coonoor, and later of the Central Research

Institute, Kasauli, where at an earlier date he was in charge of the Serum and Vaccine Department. In 1947 he went to West Africa to create an institute for research into all aspects of trypanosomiasis, both in human beings and in domestic animals. This task is now completed, and the West African Institute for Trypanosomiasis Research is an actively functioning and successful organization. Colonel Mulligan is the West African representative on the Scientific Council for Africa, and a member of the International Scientific Committee for Trypanosomiasis Research and of the World Health Organization Expert Panel on Parasitic Diseases. During the past three years he has been engaged in planning the co-ordination of medical research activities in the West African Colonies. His efforts in this matter did much to pave the way for the inauguration of the West African Council for Medical Research, which was established by ordinance a few months ago.

Comptroller-General of the Patent Office:

Mr. J. L. Girling

MR. JAMES LAWRENCE GIRLING, who has been appointed comptroller-general of Patents, Designs and Trade Marks in succession to the late Sir John Blake, was born on July 8, 1901, and was educated at Eastwood Ho! College, Felixstowe, during 1910-14 and at Ipswich Secondary School 1914-18. He became a Draper's Scholar at East London College during 1918-21. He was awarded a London B.Sc. degree with second-class honours in electrical and mechanical engineering and in his last year studied civil engineering. Mr. Girling was appointed to the Patent Office as an assistant examiner in November 1921, was promoted to examiner in 1927 and to senior examiner in 1937. He served in the R.A.F. from 1939 until October 1945, leaving with the rank of squadron leader. He was promoted to the grade of principal examiner in the Patent Office *in absentia* in April 1944 and superintending examiner in April 1950, and was called to the Bar at Gray's Inn in the same year.

European Organization for Nuclear Research

THE European Organization for Nuclear Research is the direct outcome of a general inquiry initiated in October 1946 by the Economic and Social Council of the United Nations into the establishment of United Nations research laboratories. It was established by the convention of July 1, 1953, adopted by representatives of Belgium, Denmark, France, the German Federal Republic, Greece, Italy, the Netherlands, Norway, Sweden, Switzerland, the United Kingdom and Yugoslavia, and will come into force when ratified by Switzerland and six other countries. A report on this general question was published in December 1948, and at a meeting of Unesco in Florence in 1950 a resolution was adopted authorizing the Director-General of Unesco to inquire into the needs and possibilities of such regional research centres and to make initial surveys of cost estimates and locations. No specific fields of research or regions were mentioned in this resolution; but out of it arose in 1952 the European Council for Nuclear Research, and two years of work has now led to the establishment of a permanent organization for nuclear research on a site at Meyrin, near Geneva. A pamphlet entitled "European Co-operation in Nuclear Research" (Unesco and its Programme, No. 11. Pp. 26. Paris: Unesco; London: H.M.S.O., 1954. 1s. net) describes the purposes and resources of

this new Organization and includes a clear account of the development of this type of international scientific collaboration and of the work of the European Council for Nuclear Research in drafting the convention and organizing other forms of co-operation in nuclear research. The cost of the activities of the Organization, including construction and equipment of the Laboratory, is estimated at £10 million for the first seven years, towards which the United Kingdom will contribute about £2.4 million. The initial equipment will include a proton-synchrotron and a synchrocyclotron designed to produce proton beams of 25 GeV. and 600 MeV., respectively. Excerpts from the convention are annexed to the pamphlet.

Steroids for Chromatography

THROUGH the co-operation between a number of fine-chemical companies and university laboratories in the United States, steroid preparations for use as reference standards for paper chromatographic techniques are now available. This service has been undertaken by the United States Pharmacopeial Convention, 46 Park Avenue, New York 16, which has announced the issue of the first set of twenty-four steroids of importance for identification purposes. Many of these have hitherto been unobtainable from commercial sources. The price of the complete set is 60 dollars; but the individual steroids can be obtained for 3 dollars each. They are diluted with talc in the proportion of 1:100, and from this mixture the steroid can be readily extracted with an appropriate solvent. Most of the steroids contain trace amounts of contaminants which will not normally interfere in chromatographic procedures. Physical data of the steroids are set out in an accompanying leaflet, which also provides information concerning the programme of the United States Pharmacopeia service. It is proposed to issue further sets of steroids, and in due course a total of fifty-two steroid standards will be available to all parts of the world.

Optical Society of America: Annual Meeting

THE thirty-eighth annual meeting of the Optical Society of America was held at the George Eastman House, Rochester, New York, during October 15-17, 1953. The meeting was preceded by a special visit to the Corning Glass Works, where more than a hundred and fifty members of the Society were greeted by Dr. E. U. Condon, the director of research, and listened to a talk by Dr. W. W. Shaver, the manager of the product development division, on applied and theoretical glass problems, and to a discussion, by members of the staff of the Corning laboratories, on the properties of fused silica. The annual banquet was given on the evening of October 16, at which the Frederic Ives Medal of the Society was presented to Prof. H. M. Randall, of the University of Michigan. At the annual business meeting on the next day the new officers were installed: *President*, Deane B. Judd; *Vice-President*, R. A. Sawyer; *Secretary*, A. C. Hardy; and *Treasurer*, W. W. Graefer. The programme of the technical sessions comprised seventy-five contributed and three invited papers. The titles and abstracts of these papers are printed in the September issue of the Society's *Journal* (43, 811; 1953), and a brief report of the proceedings of the annual meeting in the November issue (43, 1126; 1953). The invited papers dealt with three-dimensional and wide-angle projection. Three-dimensional presentation with polarized light

was discussed and demonstrated by E. H. Land; the cinemascope method of wide-angle photography by J. R. Benford; and the cinerama process by F. Waller (read in his absence by F. Tuttle).

Grant-aided Agricultural Colleges in Britain

THE Minister of Agriculture and Fisheries has appointed a committee to inspect the grant-aided agricultural colleges, with the following terms of reference: "To examine and report to the Minister of Agriculture and Fisheries on the work of the grant-aided Agricultural Colleges and to make recommendations as to the grants to be made to them for the five academic years beginning October 1, 1954". The members of the Committee are: Dr. K. A. H. Murray, chairman of the University Grants Committee; the Hon. Mrs. Ralph Ascheton, a land agent and farmer in Lancashire; Prof. H. G. Sanders, professor of agriculture, University of Reading; and Mr. G. A. Nott, a leading West Midlands farmer.

Scholarship Grants for Education in Plastics

THE trustees of the Plastics Industry Education Fund have recently announced that, in addition to allotting £1,000 for the third year in succession for training grants to students working full time for a science degree, £1,000 a year for the next two years has been allotted for bursaries for students taking the two-year diploma course at The Borough Polytechnic, London. This course, which was started last September, has proved very useful in training young men wanting to enter the industry. To increase facilities for training in plastics technology in the Midlands, £1,000 a year for the next two years has been allocated for scholarships to students taking the full-time associateship course at the Birmingham College of Technology. This course has been available for some time, and it is hoped that the offer of scholarships will induce sufficient students to undertake the course and keep it going from year to year.

Lady Tata Memorial Trust: Awards

THE following new awards have been made by the Lady Tata Memorial Trust for research on leukaemia and allied diseases: *Grants for research expenses*, Dr. A. Sreenivasan (Department of Chemical Technology, University of Bombay); *Scholarships (whole-time or part-time)*, Dr. J. Ringsted (Fibiger Laboratories, University Institute for Pathological Anatomy, Copenhagen) and Dr. J. Rygaard (Radium Institute, Copenhagen); *Part-time scholarship and grant for research expenses*, Dr. M. Seligmann (Institut Pasteur, Paris). In addition, the various awards to the following research workers, which have previously been announced (see *Nature*, 171, 1098; 1953), will be renewed for another year: Dr. F. Klemmeyer-Nielsen and Dr. N. A. Stenderup (Aarhus), Dr. J. Nordmann and Dr. R. Robineaux (Paris), Dr. J. Kieler and Dr. Ragna Reak-Nielsen (Copenhagen), Dr. Astrid Fagraeus and Dr. B. Thorell (Stockholm), and Dr. G. Negroni (London).

Exhibition in Manchester of the North-West Branch of the Institution of Electronics

THE ninth annual exhibition of the North-West Branch of the Institution of Electronics will be held in the Manchester College of Technology (Sackville Street, Manchester) during July 14-20 (10 a.m.-10 p.m.; except July 14, 2.30 p.m.-10 p.m.; and July 17, 10 a.m.-7 p.m.). The exhibition will consist of two sections: a scientific and industrial research

section, composed of displays from universities, research associations, hospitals, etc.; and a commercial section devoted to manufacturers' products. Altogether there will be displays from more than fifty exhibitors. In addition to an extensive programme of lectures and film shows, visits will be arranged to the University of Manchester Computing Department. Exhibition catalogues (1s. 6d. post paid), lecture and film show programmes (4½d. post paid) and further information are available from the honorary exhibition organizing secretary, W. Birtwistle, 78 Shaw Road, Thornham, Rochdale, Lancs.

Congress In Leyden of the International Society for Cell Biology

THE eighth congress of the International Society for Cell Biology, known as the Cytology Congress, will be held in Leyden during September 1-8, under the presidency of Prof. E. Newton Harvey, of Princeton University. Full members of the Society, and candidates for membership approved by the International Committee, are automatically entitled to attend the congress and to introduce one guest. The programme of symposia, at which invited papers will be read, will include the following topics: induced enzyme synthesis; the formation of the intracellular matrix in plant and animal tissues; immunobiological concepts of cellular growth and differentiation; biochemistry of gene action; thyroid secretion; nuclear and chromosome structure; mitochondria; cell division and mitotic poisons; morphogenetic interactions between cells; virus synthesis; the active cell surface; and submicroscopic structure of cytoplasm. The sessions on mitochondria, nuclear and chromosome structure and submicroscopic organization of cytoplasm form a special conference on the "Fine Structure of Cells", held under the auspices of the International Union of Biological Sciences. At the general sessions members and their guests may contribute papers on topics of their own choosing, and notification should be made before July 1. Further information can be obtained from the secretary of the Congress, Dr. W. K. H. Karstens, Botanical Laboratory, Nonnensteeg 3, Leyden.

In conjunction with the congress, the National Museum for the History of Science, Steenstraat 14, Leyden, is organizing an exhibition, "From Magnifying Glass to Eye of Science", to be held during June 25-September 19. The exhibits will include microscopes, demonstrations of instruments, drawings, manuscripts and portraits, etc., from the period of about 1630-1880. A catalogue will be available.

Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: J. W. Pursglove (senior agricultural officer, Uganda), director of botanical gardens, Singapore; G. D. Shaw (veterinary officer, Northern Rhodesia), chief veterinary research officer, Northern Rhodesia; B. L. Mitchell (teetee entomologist, Nyasaland), biologist, Game and Teetee Control Department, Northern Rhodesia; G. D. Stockwell, veterinary officer, Tanganyika; E. S. Clayton, economist/statistician, Economic Research Division, Kenya; W. S. Foster, soil survey officer, Nigeria; R. A. Smart, assistant conservator of forests, Northern Rhodesia; J. H. Smith, veterinary officer, Nigeria; T. F. Twist, meteorologist (British Caribbean Meteorological Service), Trinidad.

Announcements

SIR HAROLD ROXBEE COX, chief scientist of the Ministry of Fuel and Power since 1948, is resigning from the public service on June 30, in order to take up appointments in the engineering industry.

THE Lord President of the Council has appointed Sir Hugh Beaver to be chairman of the Advisory Council for Scientific and Industrial Research in succession to Sir Ian Hailbron, who retires on September 30 on completion of his term of office. Sir Hugh Beaver, who has been a member of the Advisory Council since 1952, is managing director of Arthur Guinness, Son and Co., Ltd.

At the University of Cambridge on June 10, honorary degrees were conferred on the following, among others: *Sc.D.*, Prof. P. M. S. Blackett, professor of physics at the Imperial College of Science and Technology, University of London, and Sir Charles Dodds, Courtauld professor of biochemistry in the University of London; *Litt.D.*, Miss Gertrude Caton-Thompson, known for her work in archaeology.

PROF. J. McCUNE, professor of veterinary anatomy in the Royal Veterinary College, London, has been appointed acting principal of the College in succession to the late Prof. J. B. Buxton.

PROF. P. PRUVOST, director of the Institut de la Houille, Paris, and *correspondant* for the Mineralogical Section of the Paris Academy of Sciences, has been elected a member of the Mineralogical Section of the Academy in succession to the late E. de Margerie.

THE following appointments have been made in the University College of North Staffordshire: Mr. A. G. N. Flew, at present lecturer in the Department of Moral Philosophy, University of Aberdeen, to be professor of philosophy; Dr. D. G. Holloway, to be assistant lecturer in physics.

DR. C. B. B. DOWNMAN, senior lecturer at St. Thomas's Hospital Medical School, London, has been appointed to the University of London readership in physiology tenable at the Royal Free Hospital School of Medicine.

THE Sports Turf Research Institute will hold a silver jubilee conference on July 1 at its St. Ives Research Station, Bingley, Yorks, in celebration of its founding in 1929. Besides the four principal lectures of the conference, facilities will be provided for inspecting the work of the Institute, and a display of machinery and equipment will be staged. Application forms for the conference, to be returned by June 25, can be obtained from the Research Station.

It is proposed to institute a special international award, to consist of a bronze medal and a scroll, for outstanding work in the field of venereal diseases and non-venereal treponematoses, the award to be administered by the World Health Organization. It is hoped to collect enough money to make it an annual award, and interested individuals and organizations are invited to contribute to the establishment of this special fund, cheques being made payable to "The International Treponematoses Award Fund". In Great Britain the temporary treasurer is Dr. R. R. Wilcox, of St. Mary's Hospital, London, W.2, and in the United States Dr. Frank W. Reynolds, of the Saratoga Spa, Saratoga Springs, N.Y.

NATIONAL ACADEMY OF SCIENCES

ANNUAL MEETING

THE ninety-first annual meeting of the National Academy of Sciences was held in Washington, D.C., during April 26-28 and was attended by about two hundred of the total of five hundred members that make up the Academy. During the meeting five sessions were devoted to the reading of about forty papers, and in addition there were three symposia of invited papers on the following important fields of current scientific interest: structure and functions of nucleic acids, under the chairmanship of Prof. Linus Pauling (California Institute of Technology); the development and significance of high-energy particle accelerators for nuclear research, under the chairmanship of Prof. I. I. Rabi (Columbia University); and scientific aspects of the International Geophysical Year, under the chairmanship of President Lloyd V. Berkner (Associated Universities, Inc.). Each year the president of a distinguished foreign academy or society is invited to address the Academy, and this year the chief guest of honour and principal speaker was Prof. Per Adolf Geijer, president of the Royal Swedish Academy of Science and formerly director in chief of the Swedish Geological Survey.

At the meeting four awards of the Academy were presented, as follows: *John J. Carty Medal*, to Dr. Vannevar Bush, president of the Carnegie Institution of Washington; *Comstock Prize*, to Dr. William Shockley, of the Bell Telephone Laboratories; *Elliot Medal*, to Prof. Raymond C. Osburn, emeritus professor of zoology, Ohio State University; and the *Public Welfare Medal*, to Dr. Alan Gregg, vice-president of the Rockefeller Foundation.

The Carty Medal, which was established by a group of friends of Dr. John J. Carty when he retired in 1930 from the vice-presidency of the Bell Telephone Laboratories, is awarded at intervals by the Academy for noteworthy and distinguished accomplishments in any field of science coming within the scope and charter of the Academy, without regard to race, nationality or creed. Dr. Bush, who has been president of the Carnegie Institution of Washington since 1939, is distinguished not only for his work as a scientist and engineer but also as an administrator and public servant. In particular, he organized the Office of Scientific Research and Development during the Second World War, which he administered in parallel with his responsibility for the development of the atomic bomb.

The Comstock Prize for advancement of knowledge in electricity, magnetism and radiant energy is awarded every five years from a fund established in 1907 by Cyrus B. Comstock, a member of the Academy. The Prize for 1953 totals four thousand dollars and is awarded to Dr. Shockley "for his pioneering investigations and exposition of electric and magnetic properties of solid materials; in particular for his researches in the conduction of electricity by electrons and holes in semi-conductors". Except for war service, when he was director of research for the anti-submarine warfare operations research group at Columbia University, Dr. Shockley's working career has been at the Bell Telephone Laboratories, which he joined in 1936, and his

researches have led directly to the development of the transistor.

The Elliot Medal, which was established in 1917 by Margaret Henderson Elliot in honour of her father, Daniel Giraud Elliot, is awarded annually for the most meritorious work in zoology or paleontology published each year. The award to Prof. Osburn this year is in recognition of his work "Bryozoa of the Pacific Coast of America", a comprehensive treatise on this complicated group of marine organisms which are of scientific interest both as living material and in fossil form and as aids to geological dating. Prof. Osburn was appointed professor of zoology and head of the Department in Ohio State University in 1917, retiring in 1942, and during 1945-53 he held the position of research associate on Bryozoa of the Hancock Expeditions of the University of Southern California.

The award of the Public Welfare Medal is made possible by a fund established in 1913 in honour of Marcellus Hartley by his daughter, Mrs. Helen Hartley Jenkins, the purpose of the Medal being "... to mark the appreciation of the National Academy for eminent service to the public, performed without a view to great monetary gains and by methods which, in the opinion of the Academy, are truly scientific". This year's recipient, Dr. Gregg, has been associated with the Rockefeller Foundation since 1919, being successively associate director, Division of Medical Education; associate director of medical sciences; director of medical sciences; and, since 1951, vice-president of the Foundation. Not only through the Foundation but in other capacities as well, Dr. Gregg has actively participated in medical education and research in the United States and abroad; in supporting the promotion of basic research, he has always been a champion of 'risk research'. As chairman of the Committee on Biology and Medicine of the Atomic Energy Commission since its organization, he has effectively guided the direction of its activities in such a way that basic research has prospered equally with other research activities, and at all times he has stood for freedom in research activities and open interchange of knowledge whenever such freedom and interchange do not jeopardize national security.

The following were elected officers of the Academy: *President*, Dr. Detlev W. Bronk, president of the Rockefeller Institute for Medical Research, New York City; *Foreign Secretary*, Dr. John G. Kirkwood, director of the Sterling Chemistry Laboratory, Yale University; *New Members of Council*, Prof. Farrington Daniels, Department of Chemistry, University of Wisconsin, and Dr. Merle A. Tuve, director of the Department of Terrestrial Magnetism, Carnegie Institution of Washington. The other officers of the Academy, who were elected in previous years and will continue until the expiry of their term of office, are as follows: *Vice-President*, Dr. George W. Corner; *Home Secretary*, Dr. Alexander Wetmore; *Treasurer*, Dr. William J. Robbins; *Members of Council*, Hugh L. Dryden, Robert F. Loeb, William W. Rubey, Wendell M. Stanley and Edwin B. Wilson.

The following have been elected members of the Academy: E. Anderson, professor of botany, Washington University, St. Louis; H. W. Babcock, astronomer, Mount Wilson Observatory, Pasadena; E. C. Bain, vice-president in charge of research and technology, United States Steel Corporation, Pittsburgh; A. K. Balls, professor of enzyme chemistry, Purdue University; J. Bardeen, professor of physics and electrical engineering, University of Illinois; W. Bloom, professor of anatomy, University of Chicago; M. N. Bramlette, geologist, Scripps Institution of Oceanography, La Jolla; W. R. Brode, associate director, National Bureau of Standards, Washington, D.C.; M. Calvin, professor of chemistry, University of California, Berkeley; B. Chance, director of the Johnson Foundation, University of Pennsylvania; R. P. Feynman, professor of theoretical physics, California Institute of Technology, Pasadena; H. O. L. Fisher, professor of biochemistry, University of California, Berkeley; J. B. Fisk, director of research in the physical sciences, Bell Telephone Laboratories, Murray Hill, N.J.; J. P. Guilford, professor of psychology, University of Southern California, Los Angeles; N. Jacobson, professor of mathematics, Yale University; G. E. Kimball, professor of chemistry, Columbia University; W. E. Lamb, professor of physics, Stanford University; E. M. Landis, professor of physiology, Harvard Medical School; E. Mayr, professor of zoology, Harvard University; W. F. Meggers, chief of the Spectroscopy Section, National Bureau of Standards, Washington, D.C.; A. E. Mirsky, member of the Rockefeller Institute for Medical Research, New York; B. O'Brien, vice-president, American Optical Company, Southbridge, Mass.; W. K. H. Panofsky, professor of physics, Stanford University; A. Petrunkevitch, professor emeritus of zoology, Yale University; A. R. Rich, professor of pathology, School of Medicine, Johns Hopkins University; J. H. Steward, professor of anthropology, University of Illinois; E. H. Vestine, chairman of the Section on Statistical and Analytical Geophysics, Department of Terrestrial Magnetism, Carnegie Institution of Washington; F. H. Westheimer, professor of chemistry, University of Chicago; R. H. Wetmore, professor of botany, Harvard University; A. E. Whitford, professor and director, Washburn Observatory, University of Wisconsin.

The following have been elected foreign associates of the Academy: Sir Macfarlane Burnet, director of the Walter and Eliza Hall Institute for Medical Research, Melbourne; Albert M. G. R. Portevin, consulting engineer, Paris; and Otto Renner, professor and head of the Botanical Institute and Garden, Munich.

REACTIONS OF THE HUMAN BODY TO INJURY

THE British Council has done good service to the serious student of disease by bringing together* a number of articles which show very clearly the changing attitude to injury reactions. No longer can this topic be considered as the sole province of pathology. Indeed, it is all too clear that no progress need be expected unless the attack be planned on the widest possible front. The chemist and physicist,

the clinician, bacteriologist and pathologist must each play his part in the study of what goes on in the injured tissues and of the factors that modify the responses until death or recovery occurs. This re-birth of the old doctrine of inter-relationship between constitutional factors and local tissue response owes a great deal to Sir Edward Mellanby, until lately secretary of the Medical Research Council and himself an original investigator in the field, and it was a felicitous thought to persuade him to write the introduction to the British Council's symposium.

Prof. G. Payling Wright tells a fascinating story about tetanus which is largely the outcome of his own recent work. Ingenious experiments have shown how the toxin of this unpleasant germ reaches the central nervous system and exerts its effects at the synapses of the spinal cord. Prof. Wright indicates how infection may be prevented and pleads for general immunization of the young.

Under the title of "Gas Gangrene", Prof. C. L. Oakley reviews the present-day knowledge of anaerobic infections. His masterly exposition of their genesis shows that changes in oxidative reduction potentials, pH requirements and various other disturbances in damaged muscle provide ideal conditions for the nourishment and growth of anaerobic bacteria. The various toxins manufactured by these organisms are characterized so far as that is possible and their modes of action discussed. In this way precision replaces empiricism in the investigation and treatment of these diseases.

Dr. J. B. Cavanagh and Prof. R. H. S. Thompson provide much food for thought in their brief but admirable review of demyelination. They conclude that several dissimilar processes, which range from deficiency states to anti-cholinesterases, have this common feature. The results of their further study will be awaited with interest, since it is likely that here again the enzymic factors will provide the clue.

An unusual article comes from Drs. J. D. Judah and W. G. Spector, who apply modern enzymological techniques to the diseased cell. Much of this information is derived from the authors' original work on poisons such as dinitrophenol and carbon tetrachloride, and it would seem that we are on the way to resolving the problem of some cell injuries in terms of biochemical disturbance. This, too, is the main theme of Dr. H. Cullum's paper on war gases, some of which interfere with enzyme systems and so lead to permeability changes in the endothelium of blood vessels and upset fluid equilibrium in the body. The latter subject is well discussed by Dr. F. C. Courtice, who defines the role of altered lymph flow from damaged tissues and assesses its connexion with haemodynamics and osmotic properties of the blood. Dr. Courtice's point of view recalls the stimulating attack made about fifty years ago by the late Prof. E. H. Starling, and possesses the special merit of being based on his own superb technique for the measurement of lymph flow.

No compilation on injury can neglect the subject of 'shock', and in this symposium full justice is done to various aspects of this elusive problem. Prof. H. N. Green and Dr. H. B. Stoner describe their stimulating hypothesis, which links shock with carbohydrate metabolism; Dr. R. T. Grant summarizes his notable clinical studies made during the Second World War and Dr. J. P. Bull draws upon his wide experience in a helpful article on burns. Shock naturally raises the question of blood transfusions, and Dr. R. Bodley Scott deals with the

* *British Medical Bulletin*, 10, No. 1 (1954). Pp. 72. (Medical Dept., British Council, 65 Davies Street, London, W.1.) 15s.

clinical aspect, while a band of workers, Sir Alan Drury, Dr. P. L. Mollison, Dr. W. d'A. Maycock and Dr. Margaret E. Mackay, review the problems of blood storage, plasma and its substitutes.

Finally, Dr. W. Ritchie Russell discusses head injuries, with an admirable blend of physiology and surgery which is a model of clinical investigation.

Each of these articles is well documented and makes good reading, since a leading principle is kept well to the fore even when information is scanty and apparently contradictory.

The scientific editor, Dr. W. G. Spector, is to be congratulated on the success of his efforts.

V. UDALL

WORKABLE PEAT RESOURCES OF SCOTLAND

WORKABLE deposits of peat, equivalent in value as fuel to twenty years output of coal, or 500 million tons, are estimated to be available in Scotland as the result of a painstaking inquiry carried out by the Scottish Peat Committee, which had been set up in 1949 and reported in 1953*. This accessible reserve occupies a total area of 1,625,000 acres, covered to a depth of 2 ft. of peat, and contains a thousand million tons of solid fuel, some 600 million tons consisting of mosses of which the depth, accessibility and other features make them suitable for utilization. In the associated inquiries into the winning and utilization of the peat, the Committee kept prominently in mind the prospect that ultimately much of the land now under peat might be reclaimed for agriculture or forestry.

In a number of European countries, perhaps more richly blessed by reserves of peat than is Scotland, peat production has been developed on a considerable scale, and mechanical methods of winning fuel have been well advanced. The various methods available were examined by the Committee. Thus, peat produced by automatic plants, with excavators, macerators and spreaders for drying, is likely to be more expensive than coal in Britain unless smaller types of machines can be made to reduce costs substantially.

Hydro-peat—that is, raw peat disintegrated into a slurry by a high-powered water-jet, pumped from the bog to a drying field and cut into blocks—might have some application if a cheap method of removing water could be devised; but the Committee considers that this is not yet practicable. In the production of milled peat a horizontal cut of about $\frac{1}{4}$ in. thickness is made, the machine operating on the same principle as a motor grass-mower. The milled peat, after preliminary drying *in situ* and harvesting, is taken to a drying and briquetting plant. The product has a net calorific value of 8,000 B.Th.U. per lb., and is relatively dense and transportable. The process requires fairly favourable climatic conditions for drying, and, accordingly, in Scotland the number of harvests might be limited to some 18–20 in a season. The cost is roughly competitive with coal as delivered to power stations in the north of Scotland.

The technical problem of greatest difficulty is to find an efficient and economical means of reducing the moisture content of peat from upwards of 90 per

cent in the raw state to a level at which it can be burned. Nearly all processes now operating commercially rely on wind and sun to do so. This makes peat production a seasonal operation with expensive seasonal labour. The application of mechanical processes was investigated, but it was found that their suitability has not reached a scale at which their commercial use could be recommended for Scottish conditions. Other processes considered include wet-carbonizing, de-watering by centrifuge and electro-osmosis; but they were all found to be less promising than pressure de-watering. There may, however, be scope for developing some other uses of peat in association with a fuel and power plant—for example, the production of moss litter, or the extraction of waxes. Other processes, such as carbonization, hydrogenation and use as a building material, are considered less hopeful.

Perhaps the most interesting and novel feature of these pioneering efforts has been the application of peat firing to the gas turbine used as a power generator. The attractive features of the gas turbine are the greater flexibility in siting, less demand for cooling water, reduced possibility of damage by abrasion from harmful constituents of its low content of ash, and greater possibilities of more efficient use of the potential heat of the fuel. Thus it may be possible to dry a wet fuel like peat from a higher moisture content by the use of the waste heat available.

The closed-cycle gas turbine has been investigated by the Scotland Hydro-Electric Board. A description is given in the present report of trials with a machine of this type, of some 500 H.P. capacity, in which a flue-gas drier was incorporated to dry peat from a moisture content of 50–55 per cent to a moisture content of 30 per cent, thus enabling it to operate with milled peat or with any of the accepted methods of peat production involving air-drying.

Another gas turbine, of 750 kW. capacity, operating on the open cycle, has been sponsored by the Ministry of Fuel and Power and is already in limited production, and regarded as having reached a stage of proved reliability. A rotary louver drum drier has been ordered and should give valuable information for application to both the open- and the closed-cycle systems. It is estimated that a small peat-burning closed-cycle gas turbine of 2,000 kW. might produce power at a cost comparable with small diesel stations of similar output, but the cost would be much higher than that of power from large hydro-electric schemes. On the other hand, once a large peat-fired plant can be developed, the Committee considers that important economies could result which would enable such a plant to produce power at a cost comparable with large coal-fired steam turbines. Since the report was drafted the Hydro-Electric Board and the Central Electricity Authority have agreed, with assistance from the Government Development Fund, to contribute towards the capital cost of establishing a 2,000-kW. peat-burning unit at Altnabreac, Caithness. Meanwhile, investigations are to go ahead on pressure de-watering and other methods of peat production. An open-cycle machine of 750 kW. and a large press ordered by the Ministry of Fuel and Power are to be included in the developments at the same station. Thus Britain has taken the lead in developing solid-fuel gas turbines. Further, the peat experiments foreshadowed in the report will be watched with great interest in a number of other countries, particularly Ireland, Sweden and Canada.

* Scottish Home Department. Report of the Scottish Peat Committee. Pp. 66+8 plates. (London: H.M.S.O., 1954.) 5s. net.

Another and perhaps no less significant feature of the report is the reference to land development following the winning of the peat. The depopulation of the Highlands may be attributed to the existence of barren areas, costly in the maintenance of social services more abundant in other parts of Britain. The conversion of the peat areas to agricultural use and afforestation requires, beyond the winning of the peat, intensive drainage, the cultivation of arable and pastoral soil conditions, and the features necessary for the planting of trees, namely, a suitable subsoil and absence of exposure to wind. Thus the Forestry Commission estimates that planting an area of twenty thousand acres might employ ultimately six hundred persons when the forest is in full production.

Thus may be seen the potentialities of a hitherto neglected site of natural resources as affected by the march of science and engineering.

R. J. SARJANT

CHEMICAL INDUSTRY IN BRITAIN DURING 1953

SUPPLEMENTING the report on the chemical industry, 1949, published in February 1950, the Association of British Chemical Manufacturers has now issued a "Report on the Chemical Industry, 1953"*, based on replies received to a questionnaire addressed to its members early in 1953. The present report adopts the same definition of chemical industry as was used in the earlier one: "the manufacture of heavy chemicals, industrial gases, fertilisers, dyestuffs, medicinal and other fine chemicals, explosives, plastics and synthetic resins, but not the compounding of chemicals to make such products as paints, insecticides, sheep and cattle dips, and pharmaceutical preparations". On this basis the industry represents about one-third of the activities covered by the definition of chemicals and allied trades used by the Ministry of Labour and National Service for its statistics.

For 1952, returns were received from 234 of the 272 firms that previously reported for 1948, and these 234 firms employed capital of £406.8 million, compared with £230.6 million in 1948, the capital of the 38 firms which failed to reply totalling less than £6 million. The total staff employed in the industry increased from 141,817 to 151,349, the scientific staff rising from 6,176 to 7,406, or roughly 20 per cent, compared with the forecast of an increase of 40 per cent in respect of chemists, by 1953, in the earlier report. Employed capital per employee rose from £1,600 to nearly £2,700 at the end of 1952, when the expansion schemes in progress involved a total capital expenditure of £138 million, with additional schemes awaiting licences or under consideration to the total of £91 million. The expenditure of £11.2 million on research and development in 1952 approximates closely to the forecast of 32 per cent increase in 1948, but the number employed on research and development only rose by 8 per cent, from 10,100 to 10,914; in the same period the number of scientific workers so employed rose from 3,000 to 3,267. When the additional laboratories and other experimental facilities, for which capital expenditure of £6.2

million is in hand, are available, recurrent expenditure on research and development will rise to £12.7 million or almost 50 per cent above that in 1948.

New products are being added to the industry's selling range at the rate of several hundred every year, and production has increased by 29 per cent in volume, compared with 15 per cent for all manufacturing industries, with an estimated increase in value of 60 per cent. Productivity increased by 21 per cent on a volume basis and 51 per cent on a value basis, these figures being attributed to the increase in employed capital, the increasing use of instrumentation for process control and the application of work study methods. Nevertheless, it has not been possible, nor will it ever be, to eliminate imports; of the £49.68 million imported in 1952, £9.3 million consisted of potassium compounds and extracts for tanning, for which there is no available indigenous supply of raw materials. Drugs, medicines and medicinal preparations were imported to the amount of £4.54 million, cellulose acetate to £2.38 million, sodium compounds to £2.97 million, vinyl resins to £1.19 million and synthetic organic dyestuffs to £0.88 million. Exports were raised from £38.25 million in 1948 to £151.7 million in 1952 (£146 million in 1953) with indirect exports of chemicals estimated at £60 million in 1952, the United States of America (£11.07 million) and India (£10.9 million) being the largest markets. Exports to all dollar markets rose from £5.62 million in 1948 to £19.05 million in 1952.

The difficulties, referred to in the earlier report in the execution of the industry's expansion schemes still exist, though they are less serious. It is much easier to obtain the necessary authorization for a new project, and the sulphur position has been eased. The scarcity of scientific and technical staff still hampers the development of the industry and its efforts to increase productivity, and the rising costs of fuel and transport are seriously affecting the competitive position of the chemical industry and other branches of British industry in the export market. The report claims that there is every prospect that the industry will continue to hold its own and expand its exports, more particularly the specialities being developed by research. The industry is also confident of its ability both to meet the new requirements of Britain's consuming industries, with their changing technologies, and to provide for the changing demands in the overseas markets where industrialization is taking place.

RECENT ADVANCES IN THE CHEMISTRY AND BIOLOGY OF THE PTERIDINES

SYMPOSIUM IN LONDON

A SYMPOSIUM sponsored by the Ciba Foundation, the twenty-fifth of its kind, was held in London during March 22-25, bringing together for the second time chemists and biologists working in the pteridine field. The programme of the symposium gave equal weight to discussions upon the chemical and upon the biological aspects of pteridine research, the former being held under the chairmanship of Prof. A. Albert, of the Australian National

* Association of British Chemical Manufacturers. Report on the Chemical Industry, 1953; a Supplement to the 1949 Report. Pp. 12. (London: Association of British Chemical Manufacturers, 1954.) 1s.

University (Dept. of Medical Chemistry, 183 Euston Road, London, N.W.1), and the latter under that of Dr. W. Jacobson (Strangeways Research Laboratory, Cambridge).

In a series of three papers, Dr. E. C. Taylor, jun. (University of Illinois, Urbana), covered the work of his school upon the degradation and synthesis of the polysubstituted pteridines, and upon the elucidation of the structure of some pyrimido-pteridines. Pteridines substituted in both the 2- and the 4-positions by amino- or hydroxy-groups undergo ring opening on aminolysis to give 2-amino-3-carbamidopyrazines, compounds which, Dr. Taylor indicated, are of particular utility in the synthesis of pteridines with substituents in the pyrimidine ring different from those of the compound degraded. Another important intermediate is 2:4:6:7-tetrachloropteridine, which can be reduced to 2:4-dichloro-5:6:7:8-tetrahydropteridine and to 5:6:7:8-tetrahydropteridine, and which forms 2:4-dichloro-6:7-diaminopteridine and then tetra-aminopteridine on treatment with ammonia. Dealing with the 'bis-alloxazine' of Wieland, Dr. Taylor reported that degradative studies show it to be a pyrimido-(5:4:6:7)-pteridine, and that such compounds can be obtained generally by the reaction between a 4:5-diaminopyrimidine and alloxan in acid solution. Dr. G. H. Hitchings (Wellcome Research Laboratories, New York) described the preparation of two tetra-aminopyrimidopteridines by aeration of a solution of 2:4:5:6-tetra-aminopyrimidine. The predominant yellow isomer on deamination by nitrous acid gives 2:4:5:7-tetra-hydroxypyrimido-(5:4:6:7)-pteridine (Wieland's bis-alloxazine), the structure of which has been established by an unequivocal synthesis. Mr. G. M. Timmis (Chester Beatty Research Institute, London) gave an account of further condensed ring systems containing the pteridine nucleus, and of de-aza-pteridines and de-aza-purines, which have been obtained from the *ortho*-aminonitroso compounds of the benzene, naphthalene, pyridine and pyrimidine series.

Discussing the monosubstituted pteridines, of which some forty are now known, Dr. D. J. Brown (Australian National University, London) indicated that the study of these compounds has given information which is an important complement to that derived from the investigation of the natural and more complicated pteridines, while the simplicity of the compounds facilitates the study of the relationships between their structure and biological activities. In general, the monosubstituted pteridines can be divided into two classes: those substituted by hydrogen-bonding groups, and those containing groups which do not give rise to intermolecular binding. The compounds of the first class are soluble only in boiling water, are stable and possess high melting or decomposition points, while those of the second class are appreciably soluble in organic solvents, are relatively unstable and melt below 200° C.

Three unresolved problems encountered in the study of monosubstituted pteridines were discussed by Prof. Albert. The first concerns the anomalous base-weakening effect of a methyl-group placed in the 4- or the 7-position of the pteridine nucleus; the second has to do with the nature of the coloured products formed by treating 2-monosubstituted pteridines with mineral acid; and the third is the question of the structural forms of 6-hydroxypteridine involved in the slow tautomerism which is revealed

by titration with alkali followed by back-titration with acid.

Dr. H. C. S. Wood (Royal Technical College, Glasgow) reported that the alkylation of 4- and 7-hydroxypteridine leads to N-alkyl-pteridones, the constitution of which has been established by degradative studies followed by unambiguous syntheses. Similarly, 2:4-dihydroxypteridine gives 1:3-dimethyl-2:4-pteridone on treatment with methyl sulphate, but, as yet, the attempted alkylation of 2- and 6-hydroxypteridine has not been successful. The ultra-violet absorption spectra of the monosubstituted pteridines was discussed by Dr. S. F. Mason (Australian National University, London). Comparisons between the spectra of the hydroxy- and methoxy-pteridines and the available N-methylpteridones suggest that the hydroxypteridines normally exist in the pteridone form, while the spectra of the amino- and dimethylamino-pteridines indicate that the aminopteridines exist in the true amino form.

Dr. G. B. Elion (Wellcome Research Laboratories, New York) described the preparation and properties of 7-pteridones substituted in the 8-position with a hydroxyethyl-group, compounds which had been prepared because of the possibility that pteridines may occur in Nature as 8-substituted sugar derivatives, analogous to the purine nucleosides. The yellow pigment isolated from the *sepio* mutant of *Drosophila melanogaster*, which was discussed by Dr. H. S. Forrest (California Institute of Technology, Pasadena), may be an 8-substituted pteridine derivative. Degradative experiments have established that the major portion of the yellow pigment is 2-amino-4-hydroxy-6-carboxypteridine and that, with a fair degree of certainty, the remaining part is a lactyl group.

Prof. M. Polonovski (Faculty of Medicine, Paris) gave an account of the isolation of the pigments xanthopterin, leucopterin and isoxanthopterin, from the organs of various insects, such as *Gonopteryx* and *Bombix*, by means of chromatography. Dr. R. G. Busnel (Laboratory of Acoustic Physiology, Jouy-en-Josas) suggested that these pigments are the end-products of the catabolism of folic acid-like precursors, as they are always accompanied by mixtures of blue fluorescent substances akin to pteroylglutamic acid in the wing scales of the *Lepidoptera*. In the metabolically active cells of *Bombix mori*, pteridines of the isoxanthopterin type, notably fluoresceyanine, are found much more frequently than derivatives of the xanthopterin type; indeed, the presence of fluoresceyanine has been demonstrated, by electrophoresis and chromatography, in the ovule and the egg of the insect, and in the chrysalis at successive stages of histolysis, histogenesis and immediately after eclosion. The fluoresceyanine isolated by Prof. Polonovski and Dr. Busnel was shown by Dr. F. Korte (State Chemical Institute, Hamburg) to be a mixture of isoxanthopterin and a small amount of a substance believed, on degradative evidence, to be 2-amino-4:7-dihydroxy-6-(α : β -dihydroxyethyl)pteridine. However, synthesis of the compound of this structure showed complete lack of identity with the minor constituent of fluoresceyanine. Attempts to elucidate the constitution of urothione, a sulphur-containing pteridine isolated from urine, were described by Prof. R. Tschesche (State Chemical Institute, Hamburg). The present evidence of degradative and synthetic experiments, together with spectral data, suggest that urothione consists

of a dihydrothienyl-(2:3:6:7)-pteridine nucleus substituted in the dihydrothiophen ring with a glycol and a methylthio-group, and in the pteridine ring with a 2-amino- and a 4-hydroxy-group.

Dr. D. B. Cosulich (American Cyanamid Co., New Jersey) gave an account of the synthesis of a series of 2-sulphonamido-4-hydroxypteridines, compounds which had been prepared with the view of combining the biological activities of the pteridines and the sulphonamides. Neither these compounds, nor a series of pteric acid analogues in which the benzoic acid group had been replaced by benzenesulphonamide groupings, displayed important biological activity. The 2:4-diaminopteridines, substituted in the 6- and 7-positions with alkyl or aryl groups, were reported by Dr. H. O. J. Collier (Allen and Hanburys, Ltd., Herts) to antagonize citrovorum factor and to do so competitively over a limited range of concentrations. It was suggested that this property is the basis of the other biological actions of the 2:4-diaminopteridines, namely, the antagonism of pteroylglutamic acid, synergism with sulphonamides, inhibition of the growth of *Streptococcus* and other micro-organisms in culture, suppression of infections of these organisms in laboratory animals, and cross-resistance with proguanil and pyrimethamine. However, Dr. Hitchings pointed out that in lactobacilli 2:4-diaminopyrimidines and condensed systems containing the 2:4-diaminopyrimidine moiety (including 2:4-diaminopteridines) inhibit growth by interfering with an earlier stage, namely, the conversion of pteroylglutamic acid into the citrovorum factor. Antithymines and antipurines, such as 6-bromouracil and 8-azaguanine, respectively, markedly potentiate the antifolate acid activities of these compounds, suggesting that the latter interfere also with the synthesis of thymine and purines. Dr. D. J. Hutchison (Memorial Center for Cancer and Allied Diseases, New York) reported that the formation of citrovorum factor from pteroylglutamic acid is inhibited in *Streptococcus* by amethopterin, and that a mutant strain has been produced which is resistant to such antagonists. The growth of the mutant strain is greatly stimulated by natural purines and is inhibited by 6-mercaptopurine, a compound effecting a metabolic interference different from that of the folic acid antagonists.

Discussing the metabolic relationships between *p*-aminobenzoic acid and folic acid in micro-organisms, Dr. D. D. Woods (Biochemistry Department, Oxford) indicated that folic acid does not render all organisms insensitive to sulphonamides, nor does it invariably replace *p*-aminobenzoic acid in promoting the growth of organisms requiring the latter. Thus it is possible that none of the established forms of folic acid is a direct intermediate on the metabolic pathway from *p*-aminobenzoic acid to coenzyme F, and that some organisms are able to convert known forms to intermediates on this pathway, while others can do so only at a low efficiency or not at all. Dr. R. H. Nimmo-Smith (Biochemistry Department, Oxford) discussed the function of folic acid in the biosynthesis of purine derivatives, suggesting that folic acid is involved in the introduction of the C₈ and perhaps the C₆ atom of the purine skeleton. The suggestion was based upon the observations that the riboside of 4-amino-5-carboxamidoimidazole accumulates under conditions where the microbiological synthesis of folic acid is deficient, and that purines have a 'sparing' effect upon the concentration of folic acid needed to support the full growth of micro-organisms requiring

this factor. Moreover, the free carboxamide supports the growth of a variety of micro-organisms possessing a nutritional requirement for purines, while labelled carboxamide gives rise to labelled adenine and other purines in both micro-organisms and mammals. In discussion, Dr. Hitchings described Greenberg's recent work which shows that folic acid with carbon-14 in the formyl group, when converted into an active form by pigeon liver or by adenosine triphosphate, quantitatively transferred the radioactive carbon to the 2-position of the purine skeleton, even in the presence of excess non-labelled formate.

Dr. M. Webb (Strangeways Research Laboratory, Cambridge) reported that folic acid antagonists retard the growth of micro-organisms and give rise to populations composed of filamentous cells which are depleted of deoxyribonucleic acid. The addition of thymine with the antagonist to the growth medium prevents the formation of filamentous cells and restores the cell deoxyribonucleic acid level to normal. It seems, therefore, that folic acid antagonists decrease the rate of deoxyribonucleic acid synthesis in micro-organisms, and so inhibit the division of nuclear material and the division of the cell. Dr. G. W. Kidder (Amherst College, Massachusetts) gave an account of the effect of folic acid analogues upon the growth of *Tetrahymena*, a ciliated protozoan possessing an absolute dietary requirement for folic acid. The multiplication of this organism is inhibited by folic acid analogues in which substitutions have been made on the ring systems, the inhibition of growth being reversed by folic acid, but not by any combination of purines and pyrimidines. The organism cannot utilize folic acid analogues in which the glutamic acid residue has been replaced by another amino-acid, indicating that it cannot hydrolyse the bond between the *p*-aminobenzoic acid portion of the molecule and the amino-acid residue.

Dr. W. Jacobson described the accumulation of cells at the metaphase stage of division in the bone marrow of leukemic patients or leukemic mice treated with folic acid antagonists. The inhibition of cell division is reversed by the citrovorum factor, but not by pteroylglutamic acid, demonstrating that the cells cannot utilize or convert pteroylglutamic acid itself. Accordingly, it seems that folic acid antagonists replace the citrovorum factor within the dividing cells, and that the citrovorum factor performs a vitally important function during the few minutes of the transition from the metaphase to anaphase stages of mitosis. Similar biological effects of the folic acid antagonists were reported by Dr. R. Bellairs (University College, London) with reference to the embryonic development of the chick. The treatment of chick embryos with aminopterin or amethopterin during gastrulation brings about a clumping of the chromosomes at the metaphase stage of cell division, and leads to a retarded, abnormal growth which is manifest notably in a failure of the neural plate to close dorsally and of the foregut floor to close off ventrally. Normal embryogeny is observed when the citrovorum factor is injected simultaneously with the folic acid antagonist, but not when pteroylglutamic acid is injected with the antagonist.

Prof. A. Haddow (Chester Beatty Research Institute, London) reported that xanthopterin brings about a marked increase in the size of the kidney of the rat, an increase caused by a greatly increased rate of mitosis leading to excessive but perfectly normal cell-division in the kidney tubules. Dr.

Jacobson described a yellow pigment, isolated from the argentaffine cells of the mammalian intestinal mucosa, which possesses a fluorescence spectrum strikingly similar to that of xanthopterin in regard to both the position and the intensity of the bands. Accordingly, it is of some interest that the argentaffine cells have been found to be much reduced in number in certain types of megaloblastic anemias. Comparing the incidence of megaloblastic anemia in India and Britain, Dr. R. H. Girdwood (Medical Department, University of Edinburgh) related the higher incidence of the disease in India to the lower folic acid content of the average Indian diet. However, the relation between the disease and folic acid deficiency is not a simple one, for it is possible to have cases of megaloblastic anemia associated with intestinal malabsorption of folic acid, without vitamin B₁₂ depletion, and yet have a normal excretion of folic acid after the injection of a test dose of pteroylglutamic acid. With reference to this problem, Dr. E. M. Coates (National Institute for Research in Dairying, Reading) reported that vitamin B₁₂ does not alleviate folic acid deficiency in chicks, nor does folic acid reduce the vitamin B₁₂ requirements of the chick.

Dr. J. Colsky (Maimonides Hospital of Brooklyn, New York) gave an account of the case histories of several leukemic patients treated with folic acid antagonists. Continuous treatment with the antagonists over a period of months was accompanied, in five out of six cases, by a disturbance of the liver functions, which resulted ultimately in severe fibrosis of the liver. Dr. Colsky suggested that the production of a folic acid deficient state by means of the antagonists may cause injury to the liver by interference with the normal metabolism of choline, methionine and betaine.

In opening the symposium, Prof. Albert paid a tribute to the discoverer of the natural pteridines, Gowland Hopkins, whose work was also appraised by Dr. Jacobson at the end of the final session in a general review of the progress achieved in the pteridine field. At the close of the symposium the members expressed their appreciation of the work of the director of the Ciba Foundation, Dr. G. E. W. Wolstenholme, and of his staff, who, by their efficient organization, had materially contributed to the success of the conference. S. F. MASON

PLEISTOCENE GEOLOGY OF BRITAIN

DATA of a novel and curious kind provide, in the words of Mr. R. G. Carruthers, an interpretation of the British boulder clay deposits which differs radically from that hitherto current. The 'orthodox' scheme, with its multiglaciation and interglacials, is disregarded altogether in a booklet entitled "Glacial Drifts and the Undermelt Theory". Instead, all the British tills and many of the accompanying glacial-fluvial deposits are explained as an "undermelt" product of one great glaciation, and "changes of some moment are suggested in the conventional North European scheme, which brings a long-sought harmony into its relations with the Alps on one hand and Britain on the other".

This contribution of Carruthers to Pleistocene geology is remarkable in several respects. Not only does it do away with the views developed by other

authors and proposes a new scheme of correlation between northern France, the Thames, East Anglia, Denmark, north Germany and the Alps, but also it raises a serious question of scientific method, which deserves to be noted here.

Relying on certain observations of the effects of subglacial melting, the author develops his 'undermelt theory'. Subglacial melting and shear-structures have for many years been known from the Scandinavian area of glaciation, though Carruthers was probably the first to note some of them in Britain. Moreover, he undertook to explain many other observations by means of this same phenomenon¹, and he eventually convinced himself that the various sheets of moraine in Great Britain all belong to the same glaciation. In doing so, he applied the interpretation he gave to a small set of observations to a very wide field (now including the whole of the formerly glaciated part of Britain) and he was happy to find that the sequence of Pleistocene deposits appeared much simpler if monoglaciation was adopted. Multiglaciation is attacked by saying that in Britain the sequence can be interpreted monoglacially. With this most workers in the field of Pleistocene geology are compelled to disagree, for reasons that are not mentioned by Carruthers and, judging from the list of references, were perhaps not known to him.

But granting that this 'undermelt theory' is possible, there remains to be assessed its degree of probability. This Carruthers does not do. The new 'possible' interpretation of the sequence of tills is, without any discussion of the conclusions of earlier authors, regarded as probable, nay, even as the only sound one. In regarding the possible as probable, Carruthers does not stand alone. It is a tendency of many scientific writers, which must be regarded as decidedly harmful. The valuable work of earlier authors which led to different conclusions is not refuted, but simply remains unconsidered, and the new theory can thus be made to appear in a spotless garb. Readers who are not themselves experts in the field will thus be misled into believing that the theory proposed is the only one worthy of consideration. From the point of view of scientific method this is a deplorable way of presenting scientific interpretations; scientists should discuss in their publications the reasons for considering their own hypothesis or theory more probable than others previously put forward.

When Carruthers undertakes to fit his British monoglaciation in with the Continental chronology, he finds "at long last, . . . re-advances and interglacial periods proved beyond a shadow of doubt". It appears that it did not occur to him that this multiglaciation of the countries from France to Denmark, the nearest neighbours of Britain, renders his British monoglaciation improbable. He goes to some length in determining the age of the Eem Sea. This effort is considerably out of date, the latest publication quoted being more than twenty years old, while several treatises in English, French and German are available from which the necessary information might have been obtained². A chronological scheme is thus developed which only the uninitiated might be prepared to consider. The four glaciations (Elster, Saale, Warthe, Weichsel) are considered separated by three interglacials, the first being represented by the Holstein clays, the middle interglacial by the Eem, and the last interglacial by the *Brassia* Beds. While the Holstein Sea is now generally placed between Elster and Saale, it is the

General nomenclature	Sea-levels	Loess of North France	Loess of Mainz Basin	Alps Moraines	North Germany
Early glaciation				"Donau" glaciation of Eberl and others	
Ante-pennultimate Interglacial	a. 60 m.	Achenheim Gravels Porto du Bois (Somme) Sollfussion		Weathering and erosion Gunz with 3 phases	? Earliest tills
Ante-pennultimate Glaciation				Weathering and erosion	
Pennultimate Interglacial	a. 35 m.	Middle Terrace St. Acheul Loess Achenheim (part)	Older Loess	Mindel with 2 or 3 phases	Elster
Pennultimate Glaciation	a. - 200 m.			Weathering and erosion Riss	Holstein Sea
Last Interglacial	{ Temperate Cool Temperate Main Monastirian + 18 m. Lower Late Monastirian + 7-8 m.	} "Argile Rouge" Loess Recent I Brown-earth	Chernozem	Last Interglacial	{ Last Interglacial with Eem transgression ? Warthe Fully temperate phase Weichsel
Last Glaciation 1	a. - 100 m.	Loess Recent I	Younger Loess I	Jungries	
Last Glaciation 1/2	Epi-Monastirian + 3 m.	Brown-earth	Brown-earth (thick)	Temperate phase	
Last Glaciation 2	a. - 70 m.	Loess Recent II	Younger Loess II	Young End Moraines Group I	
Last Glaciation 2/3	a. - 10 m.	Traces of brown-earth	Brown-earth (thin)	Very weak weathering	Climate cool
Last Glaciation 3	a. - 30 m.	Loess Recent III (Rhine Valley only)	Younger Loess III	Young End Moraines Group II	Late Weichsel stages
Post-glacial	Flandrian	Brown-earth	Chernozem degraded	Retreat of ice with altered oscillation	Retreat, with altered oscillation

second interglacial of the Pleistocene on this count, the first being represented by very few sites on the fringe of the Scandinavian glaciation area. The Eem phase belongs to the last interglacial in the climatic sense and is placed by Woldstedt, the foremost authority on Germany, between Warthe and Weichsel. (This is the Last Interglacial in Woldstedt's chronology, since he now regards Warthe as an after-phase of Saale. The uncertain position of the Warthe phase, however, need not obscure the larger issue.) Moreover, that new, cold-loving animals like the woolly rhinoceros and the mammoth should have appeared during the Last Interglacial is flatly contradicted by the evidence, and the flora which, apart from *Brassica*, included the walnut and *Thuja* in Central Europe, is definitely warm.

Carruthers holds that "once established, the application of this scheme to the Alps on the one hand and to Britain on the other presents no difficulty; all goes smoothly from the start". Again, the smoothness is the inevitable result of the neglect of other workers' labours. Calling Elster the First Glaciation of the Scandinavian sheet (which according to several workers it was not), it is equated with Alpine Gunz, and Saale with Alpine Mindel. This suggestion will find no followers in either North Germany or the Alps, for reasons which have been amply published. The correlation of Saale with Riss of the Alps is regarded as sound by all who have worked on this problem in the field.

Moreover, the lengths and temperatures of the interglacials were not as Carruthers considers them to have been. According to him, "both the First and Last Interglacial, while having their warm spells, were predominantly cold periods; the middle one was warm, more so even than today, and only at the close did it turn cool". While the second half of this statement agrees with the evidence in a broad sense, the First and Last Interglacial cannot be called

predominantly cold periods. That is amply shown by their faunas, which comprise frost-sensitive elements like hippopotamus and the macaque in Western Europe, but above all by the fossil soils of the European loess belt. It is impossible in this brief discussion to present the evidence in full. The Last Interglacial, for example, was warm enough in northern France to lead to the formation of sub-Mediterranean brown-earths. Correspondingly, there were large islands of chernozem in the Mainz basin, south of the Hartz Mountains and in Bohemia, Moravia and Lower Austria. At the same time, the *Strombus* fauna indicates warmer conditions in the Mediterranean and the Eem fauna similar conditions in the Atlantic.

A further complication adds to the difficulties in Carruthers's scheme. The glaciations were not simple cold periods but groups of phases separated by short interstadials, during which the climate quite often became temperate again. Similarly, the interglacials were interrupted by cool phases. The existence of such minor phases is universally accepted on the Continent, and they cannot be disregarded in attempts at correlation. The picture that has emerged for the Last Glaciation, and which was discussed at great length at the congress last year of the International Association on Quaternary Research (INQUA) in Rome and Pisa, and afterwards at the meeting of the German section in Stuttgart, is shown in the accompanying table.

There was general agreement that between phases here called Last Glaciation 1 and Last Glaciation 2, there intervened an interstadial with fully temperate conditions, so that Last Glaciation 1 can, if one likes, be regarded as an independent glaciation. No general agreement has been reached yet, however, about nomenclature. The system used by me is a general one, and it applies in particular to the loess belt. In the Alpine foreland, the geological surveys have

called Last Glaciation 1 "Jungries", while the same phase is the Würm 1 of Soergel of thirty years ago. In north Germany, it is conceivable that the independent position of Warthe may lead to its correlation with this "Jungries", with an interstadial of interglacial character following and the Last Interglacial (with the Monastirian sea-levels of 18 and 7.5 m.) preceding. That this long interstadial was actually as warm as a full interglacial is confirmed by its independent fossil shore-line, which lies at about 5 m.⁷

The picture of fluctuations of the climate during the Pleistocene, therefore, is of great complexity, and many years will pass before the sequences found even in European countries can be correlated in detail. But no correlation can afford to neglect the minor oscillations established in so many localities, and one is glad to notice that to the expert it becomes increasingly difficult to mistake one of the major interglacials for another.

RANGE-ENERGY RELATION IN NUCLEAR TRACK EMULSIONS FOR PROTONS OF ENERGY UP TO 21 MeV.

By DR. W. M. GIBSON

Physics Department, The Queen's University, Belfast

D. J. PROWSE

H. H. Wills Physics Laboratory, University of Bristol

AND

PROF. J. ROTBLAT

Physics Department, Medical College of St. Bartholomew's Hospital, London, E.C.1

PHOTOGRAPHIC emulsions are being used to an increasing extent for accurate measurements in nuclear physics. It is therefore important that the relation between the energy of a particle and its range in an emulsion of specified moisture content should be known precisely over as wide an interval of energies as possible.

The first range-energy relation for concentrated emulsions was given in 1947 by Lattes, Fowler and Cser¹ for protons of energy up to 13 MeV. Many measurements have since been made, however, and it has been realized that atmospheric conditions can affect the amount of moisture in the emulsion, hence varying the stopping-power. It has become usual to quote the range-energy relation for dry emulsion,

the term 'dry' indicating not that water was entirely absent, but that the emulsion has been kept under vacuum for long enough for its moisture content to approach a constant value. According to the information supplied by Ilford Ltd., this value is about 0.06 gm. of water per c.c. of emulsion; this gives an emulsion of density about 3.04 gm./c.c. Rotblat² has given a relation for dry emulsion for proton energies up to 15 MeV., Catala and Gibbon³ for energies up to 16 MeV., and Bradner, Smith, Barkas and Bishop⁴ for energies up to 40 MeV. The last, however, do not claim great accuracy because of incomplete control of the moisture content.

The present results have been obtained from a series of measurements on two groups of protons from each of the reactions $^{16}\text{O}(d,p)^{17}\text{O}$ and $^{12}\text{C}(d,p)^{13}\text{C}$. The reactions took place in oxygen and acetylene gas, respectively, through which passed the 19-MeV. deuteron beam from the University of Birmingham cyclotron; the products emitted at angles between 15° and 165° were allowed to enter photographic emulsions held in a camera described by Burrows, Powell and Rotblat⁵. Before exposure, the plates (Ilford O2) were dried by evacuation in the presence of phosphorus pentoxide, for a minimum period of 12 hr. in the case of emulsions 400 microns thick, or 6 hr. with emulsions 200 microns thick. They were then transferred rapidly to the scattering camera, which also contained phosphorus pentoxide; the camera was evacuated for a further period before being filled with the appropriate pure dry gas.

RANGE-ENERGY RELATION FOR PROTONS IN ILFORD O2 EMULSION

Range (microns)	Energy (MeV.)	Range (microns)	Energy (MeV.)	Range (microns)	Energy (MeV.)
40	2.01	720	11.72	1,400	17.80
80	3.18	760	12.10	1,440	17.59
120	4.01	800	12.47	1,480	17.88
160	4.79	840	12.83	1,520	18.16
200	5.48	880	13.18	1,560	18.44
240	6.13	920	13.53	1,600	18.71
280	6.72	960	13.87	1,640	18.98
320	7.28	1,000	14.21	1,680	19.25
360	7.82	1,040	14.54	1,720	19.52
400	8.33	1,080	14.86	1,760	19.79
440	8.80	1,120	15.18	1,800	20.06
480	9.25	1,160	15.50	1,840	20.31
520	9.69	1,200	15.81	1,880	20.57
560	10.13	1,240	16.12	1,920	20.82
600	10.54	1,280	16.42	1,960	21.07
640	10.94	1,320	16.72	2,000	21.32
680	11.34	1,360	17.01		

The ranges were obtained by microscopic examination of the plates; small corrections were made for the effect of the gas traversed before the emulsion was reached, and for the foreshortening of the tracks resulting from the fact that the particles entered the emulsions at angles of a few degrees. The precision of range measurements on individual tracks was ± 2 microns. Multiple scattering causes slight changes in the angle of dip along the length of each track, but it is not usual to make any allowance for the effect of this on the observed range. The average magnitude of the effect has been considered elsewhere⁶.

The energies were obtained from the known Q-values of the reactions, the angles of emission, and the energy of the incident deuterons. The Q-values used⁷ were 1.918 and 1.045 MeV. for $^{16}\text{O}(d,p)^{17}\text{O}$ and 2.723 and -0.363 MeV. for $^{12}\text{C}(d,p)^{13}\text{C}$. The angles of emission were known accurately from the map of fiducial points⁸ giving the co-ordinates of the area scanned on the plate. The energy of the incident

Fig. 1. Logarithmic plot of range-energy relation: $\circ$ —, results from the reaction $^{14}\text{O}(\text{d}, \text{p})^{15}\text{O}$; $+$ —, results from the reaction $^{14}\text{O}(\text{d}, \text{p})^{15}\text{O}$. The horizontal lines give an indication of the uncertainty in range resulting from straggling. The straight line represents the relation $E = 0.2487 R^{2.544}$.

deuterons was found from the range of the elastically scattered deuterons, with the aid of the range-energy relation of Rotblat³. Most of the deuteron energies measured were of the order of 16 MeV., and the range of a 16-MeV. deuteron is twice that of an 8-MeV. proton. The present results are therefore based on Rotblat's figures in the region of 8 MeV.; since this part of the range-energy relation is known extremely accurately, there can be little uncertainty in the results.

A least-squares method was used to find the simple power law which fitted best to the new results and also to the figures given by Rotblat for energies greater than 7 MeV. All the groups of measurements were found to be mutually consistent, the mean deviation of the seventy individual measurements from the best curve being 0.6 per cent in energy. Over the limited region between 10 MeV. and 21 MeV., the range-energy relation can be represented by the formula

$$E = 0.2487 R^{2.544},$$

E being measured in MeV. and R in microns; there is no evidence for a departure from this relation greater than the experimental error. At lower energies we assume the almost identical results of Rotblat, and Catala and Gibson, to be correct.

The results are shown in Fig. 1, but for the convenience of readers the final relation from zero to

21 MeV. is given in the form of a table. The probable accuracy of the energies is about 0.3 per cent. For ranges greater than 800 microns the energy values are about 0.5 per cent greater than those given by Rotblat and by Catala and Gibson, and they are more than 1 per cent greater than those given by Bradner *et al.*⁴. There is good agreement with the results of Panofsky and Fillmore⁵ in the region of 700 microns. Agreement with the theoretical curve obtained by Vigneron⁶ is, however, not very good.

We wish to thank Profs. C. F. Powell and W. E. Burcham for their interest and assistance, Mrs. B. M. Herman, Miss S. Dennison and Miss J. Holmes for much of the microscope work, Mr. R. G. Freemantle and the staff of the Birmingham cyclotron for helping in the exposures, and the Nuffield Foundation and the Department of Scientific and Industrial Research for financial assistance. A Method for the Measurement of the Distance of Radio Stars

THE existence of a large number of discrete sources of extraterrestrial radio radiation (radio stars) has now been established. For the majority of the sources there is no information about their distance; only a few have been identified with celestial objects observed photographically. Attempts to measure the radio parallax of the sources have been made by Ryle¹, Mills and Thomas² and Smith³. These experiments failed to measure any parallax and could only establish that the radio stars were at a distance greater than $\frac{1}{2}$ parsec. The present communication describes a new method for the measurement of the distance of radio stars in the Galaxy, and gives preliminary results for the two intense sources in Cygnus and Cassiopeia.

The method depends upon the absorption of the radiation from the radio stars by interstellar hydrogen at a frequency of about 1,420 Mc./s., corresponding to the spectral line of the ground-state of the neutral hydrogen atom⁴. If the radiation from the source traverses neutral hydrogen in the Galaxy, it will suffer absorption at the line frequency, whereas its emission at neighbouring frequencies will be unaffected. The method assumes that the spectrum of the radio star is continuous, and does not show line structure at this frequency. The spatial distribution of the neutral hydrogen⁵ can be obtained from a knowledge of its 21-cm. emission line profile using Oort's⁶ model of the Galaxy, since the precise emission frequency of the neutral hydrogen depends upon the velocity of the gas relative to the observer, which in turn depends upon its distance from the sun. Thus from observations of the spectral distribution and the magnitude of the absorption, the distance of the radio star can be estimated.

The shape of the profile of the hydrogen emission line in the direction of the radio stars in Cygnus and Cassiopeia has been measured using a radio spectrometer in conjunction with an aerial of 1.5° beam-width. These profiles are shown in Fig. 1. The complex shape of the line profile arises from Doppler effects introduced by differential galactic rotation. The frequency scale has been calibrated in terms of distance by using Oort's model of the Galaxy. The peaks in the line profiles correspond to spiral arms in the Galaxy and agree with the distribution of gas in the galactic plane given by Oort and Muller as illustrated in Fig. 2. In the Cygnus region the undisplaced peak in the profile is associated with the hydrogen in a spiral arm which is at approximately

Fig. 1. Intensity-frequency scans of the (a) Cassiopeia and (b) Cygnus regions of the Galaxy. The intensity is given in arbitrary units which are the same for both profiles

the same distance as the sun from the galactic centre. In this case the direction of the radio star lies along a spiral arm for a distance of 4,500 parsecs. The second peak corresponds to emission from an outer arm at a distance of 9,500 parsecs from the sun. In the direction of Cassiopeia, the gas in the nearer arm is at 500 parsecs, and that in the outer arm is at 2,500 parsecs from the sun.

The intensity of the Cygnus and Cassiopeia sources has been measured at two frequencies corresponding to the two peaks of the line profiles shown in Fig. 1. The intensity of the radiation in the absence of absorption has been established by measuring the mean intensity observed at two frequencies displaced $\pm \frac{1}{2}$ Mc./s. from the frequency of the peaks in Fig. 1. The actual absorption is then obtained from these measurements, as shown in Table 1. In order to establish the distance of the radio stars from these results, it is necessary to know the total absorption which would be suffered by the 21-cm. radiation if it completely traversed the gas in the spiral arms in the directions indicated in Fig. 2. This has been calculated by comparing the measured intensity of the emission line in the direction of the galactic anti-centre with that observed from the spiral arms in the direction of the radio stars. The values are given in Table 1. It has been assumed that the gas in the direction of the

Table 1

Radio source		First peak (nearer arm)			Second peak (outer arm)			
Galactic longitude	Galactic latitude	Distance of gas (parsecs)	Total absorption*	Observed absorption ratio†	Distance of gas (parsecs)	Total absorption*	Observed absorption ratio†	
Cygnus	44.0°	+ 4.6°	0-4,500	0.5	0.62 ± 0.06	9,500	0.3	0.28 ± 0.18
Cassiopeia	79.5°	- 1.9°	500	0.5	0.30 ± 0.06	2,500	0.6	0.16 ± 0.10

* The total absorption is that expected for complete traversal of the spiral arm.

† The observed absorption ratio is defined as $\frac{I_b - I_a}{I_b}$, where I_a is intensity on the hydrogen-line frequency, and I_b is intensity $\pm \frac{1}{2}$ Mc./s. from the hydrogen-line frequency.

Fig. 2. A schematic diagram of the distribution of neutral hydrogen in the general direction of Cygnus and Cassiopeia. Full line through the sun is locus of points the same distance from the galactic centre as the sun.

galactic centre is completely opaque at the frequency of the emission line, in accord with the results of Oort.

The results in Table 1 show that the radiation from the Cygnus source is absorbed in both arms of the Galaxy; the observed absorption is of the order of that expected for the two arms. The distance of the source is therefore greater than 9,500 parsecs. Minkowski¹ has identified the Cygnus source as extragalactic and has associated it with two galaxies in collision at a distance of 34 megaparsecs. The present result is therefore consistent with this identification.

In the case of the Cassiopeia source, the absorption is very much less than that which would be expected if the radiation traversed the spiral arms—a result which indicates that the source lies within the Galaxy. However, the results are not sufficiently accurate to establish with certainty whether the source lies within the first spiral arm or in the region between the first and second arms. The relatively greater amount of absorption observed in the first peak suggests that the source lies within the first spiral arm. The present result, therefore, establishes that the distance of the source is not greater than 2,500 parsecs and that it probably lies between 500 and 2,500 parsecs. It can be anticipated that more accurate measurements of the absorption spectrum will reduce this uncertainty. Much interest has been focused on the distance of the Cassiopeia source; Minkowski¹ has suggested that it may be 300 or 500 parsecs, so that the tentative results suggested here are not incompatible with his estimate. The technique of measurement is now being refined in order to extend the measurements to other radio stars.

We wish to thank Dr. C. G. Little for suggesting the method and Prof. A. C. B. Lovell and Mr. R. Hanbury Brown for their interest and help. One of us (D. R. W. W.) is indebted to the Department of Scientific and Industrial Research for a maintenance grant.

Rock Magnetism and Polar Wandering

It is now generally accepted that lava flows become permanently magnetized in the direction of the local geomagnetic field when they cool down through their Curie point¹. Similarly, most sediments, on deposition, acquire a weak magnetic polarization². This magnetization is thought to be due to lining-up of the minute permanently magnetized particles of the ferromagnetic minerals as they sink to the bottom. If used with caution, studies of rock magnetism may therefore yield valuable data concerning the direction of the geomagnetic field in the past.

Several studies are available of the direction of magnetization of comparatively recent igneous and sedimentary rocks (lava flows and varved clays). They are shown in Table 1. These data have been used for calculating a mean direction of magnetization and Fisher's³ radius of the circle of confidence (θ) for $P = 5$ per cent. This mean direction has been compared with the direction of the (theoretical) dipole field and the angular difference determined; these figures are also shown in Table 1. The dipole field is the field due to a geocentric axial dipole; its declination is zero, its inclination (I) is calculated from the formula

$$\tan I = 2 \tan \lambda,$$

when λ is the geographical latitude of the locality.

Table 1. MEAN DIRECTIONS OF THE NATURAL PERMANENT MAGNETIZATION OF COMPARATIVELY RECENT IGNEOUS AND SEDIMENTARY ROCKS

Description	Period covered, in years	Mean direction of magnetization		Fisher's θ for $P = 0.05$	Angle with dipole field
		Declination	Inclination		
Historical lava flows of Mount Etna ⁴	2,800	N. 4.3° E.	+55.8°	2.0°	1.3°
Postglacial lava flows of S.W. Iceland ⁴	4,000	N. 1.1° E.	+73.8°	8.2°	2.5°
Varved clays of the U.S.A. ⁵	6,000	N. 4.5° W.	+51.4°	10.0°	10.0°
Varved clays of Sweden ⁶	1,000	N. 2.6° W.	+73.4°	8.8°	2.4°

The magnetic stability of these rocks can be demonstrated.

Table 1 shows that for the Etna flows, θ for $P = 5$ per cent amounts to 2.0°. This means that the probability is only 5 per cent that the true mean direction of magnetization will deviate by more than 2.0° from the calculated mean direction. We note that the dipole field direction deviates by only 1.3° from the calculated mean direction. A similar situation is encountered for the three other groups in Table 1. In none of these cases does the angle between the mean direction of magnetization and the dipole field direction exceed θ for $P = 5$ per cent. The conclusion is therefore drawn that in recent geological times, and taken over a period of several thousand years, the magnetic poles have centred on the geographic poles.

Assuming that the same conclusion holds for the geological past, we may draw conclusions concerning the position of the geographic poles in the past from the mean directions of magnetization of groups of older rocks. These mean directions for some groups are shown in Table 2. Also are shown Fisher's θ for $P = 0.05$ and the angle between the mean direction and the present theoretical dipole field (that is, the field due to a geocentric dipole directed along the present geographical axis).

Table 2. MEAN DIRECTIONS OF THE NATURAL PERMANENT MAGNETIZATION OF TERTIARY AND QUATERNARY IGNEOUS ROCKS

Age	Country	Mean direction of magnetization		Fisher's θ for $P=0.05$	Angle with present dipole field
		Declination	Inclination		
Early Quaternary	Iceland ⁴	N. 10° E.	+75°	6.9°	15°
Pliocene	France ⁴	N. 17-0° E.	+62-6°	12.5°	8.0°
Pleistocene	France ⁴	N. 3-3° W.	+51.1°	14.0°	12.8°
Miocene	Iceland ⁴	N. 1-5° E.	+77-8°	5.5°	0.8°
Pliocene	France ⁴	N. 5-5° W.	+73-3°	15-6°	3.1°
Miocene	England ⁵	N. 21.1° E.	+57-2°	10.8°	11-9°
Oligocene	France ⁶	N. 43.1° W.	+78.1°	23.7°	12-5°
Oligocene	Scotland ¹¹	N. 14-0° E.	+60.2°	5.4°	11.5°
Eocene	Ireland ¹²				

For all these groups the magnetic stability can be demonstrated; for most it follows from the fact that they are reversely magnetized. For our purpose it is irrelevant whether this reverse magnetization is due to a reversal of the main geomagnetic field or to a self-reversing mineral or combination of minerals in the rock^{4,12}. Where necessary, the opposite of the mean direction has, therefore, been recorded in Table 2.

Table 2 shows that, except in two cases, θ for $P = 5$ per cent exceeds the angular difference between the calculated mean direction and the present dipole field. For the Oligocene data from France, the difference between θ and the above-mentioned angular difference is so small that little can be proved either way. However, for the Eocene lava flows of Northern Ireland there can be no doubt that the mean direction of magnetization is significantly different from the present dipole field direction.

These results are more easily discussed when represented graphically. This will not be done here; but the procedure followed may be summarized briefly. The mean direction of magnetization with its circle of confidence is plotted on a stereographic projection. Several points on this circle are selected and considered as dipole field directions due to a non-axial geocentric dipole. The corresponding position of the magnetic poles can be easily calculated and consequently a locus can be constructed on the earth's surface, which corresponds to the circle of confidence. We may then say that the probability is 95 per cent that the geographic pole was situated within the locus during the period when the group of rocks we have used were formed. It need scarcely be said that for all groups in Table 2, except for the Oligocene rocks from France and the Eocene rocks from Ireland, the present geographic north pole is situated inside the locus.

Comparison of these loci with the alleged paths of the geographic north pole during geological time, as suggested, for example, by Kreichgauer, Köppen and Wegener, Milankovitch, and Köppen, shows that these paths cannot be reconciled with the new data. The amount of polar wandering in Tertiary and Quaternary times suggested by these theories is far too large. Even if one allows for (1) the alleged crustal shortening due to the Alpine orogeny, (2) possible uncertainties in the age determination of some of these groups of rocks, and (3) possible geological differences between the Continent of Europe and Iceland, this discrepancy remains.

However, the results from the Eocene flows of Ireland indicate that some change in the position of

geographic axis relative to Ireland may have taken place. Whether this is due to a movement of the entire crust relative to the earth's axis, or whether it is a movement of the entire Eurasian continent (or perhaps only of Ireland by itself) relative to the ocean floor and the earth's axis, we cannot say from these data. In any event, the movement, if real, is small and has not exceeded 5-10° since Eocene times.

A more detailed account of this work will be published elsewhere.

I wish to thank Mr. B. C. Browne and Dr. S. K. Runcorn, of the Department of Geodesy and Geophysics, University of Cambridge, for the interest they have taken in these investigations.

Effect of Surface Diffusion on Rates of Adsorption

SOME striking results on the rates of adsorption of nitrogen on tungsten have recently been obtained by a flash filament technique¹. The rate of adsorption is expressed in terms of a 'sticking factor', s , the probability that a molecule striking the surface shall remain there. It is found that the sticking factor at 300° K. remains constant independent of surface coverage, θ , until there is about one nitrogen atom for every four tungsten atoms. As the temperature is increased by steps to 1,100° K., s both decreases for any given θ and also starts to fall off at lower surface coverages. It would seem that the decrease of s with rising temperature would not be expected from the usual picture of activated adsorption. Furthermore, although the decrease of rate with increasing θ may be influenced by repulsive forces between the adsorbed atoms, the decrease might be supposed to take place at a fixed θ , that is, at a certain distance between adsorbed atoms, and not to change with temperature as was found. Similar behaviour has been observed earlier for adsorption on catalysts, namely, a constant rapid rate of adsorption extending up to high surface coverages followed by a swift decrease as saturation is reached. A rate proportional to $\exp(-a\theta)$ has been proposed².

These results may be given a qualitative explanation by supposing that the adsorbate is able to migrate over the surface before being either desorbed or adsorbed in a particularly favourable position—a 'centre', formed possibly by some surface irregularity. If an atom is able to 'visit' such centres, a proportion θ of which are already filled, then the probability

that an atom is adsorbed on a centre is equal to the probability of its finding at least one centre unoccupied, that is, $1 - \theta^n$. Thus, if k is the number of atoms per second striking unit surface, the rate of adsorption will be given by $k(1 - \theta^n)$, as compared with the simple Langmuir expression $k(1 - \theta)$. With n large, the rate of adsorption remains approximately equal to k until θ is near 1, a behaviour similar to the $\exp(-a\theta)$ law.

The number n may be evaluated by supposing the atoms to move over the surface by activated diffusion, or as may be appropriate in some cases, by considering the atoms on the surface to form a two-dimensional gas. In both cases, n will be proportional to τ , the length of time spent by the atoms on the ordinary surface. τ is proportional to $\exp(E/kT)$, where E is the energy of adsorption on this surface. Thus, when T is small, n is large and the rate of adsorption does not fall off until $\theta \sim 1$. As T is increased, n decreases, and the rate of adsorption starts to fall off at lower θ .

Similar results may be expected for desorption. Two probabilities, k' and k'' , will exist for movement of an atom directly from a centre to the gas and for movement from a centre on to the ordinary surface. A subsequent desorption from the ordinary surface will take place provided the atom does not become attached to another centre. The probability of not finding another centre is θ^n , where n is the number of centres visited. The rate of desorption is therefore given by $k'\theta + k''\theta^n$. At low temperatures, and hence for a high value of n , the result is a rapid desorption falling roughly exponentially to a lower value given by $k'\theta$. As the temperature is raised and n lowered, the rapid desorption is maintained to lower values of surface coverage.

A result similar to this has been obtained by Langmuir for the desorption of thorium, oxygen and caesium from tungsten³. After a fast desorption, the rate drops to a lower value at a surface coverage which decreases with increasing temperature. Langmuir suggests that the desorption follows an exponential law proportional to $\exp(+b\theta)$.

I am indebted to Prof. G. Halsey for directing my attention to the results of Becker and Hartman and for helpful discussion.

Crystal Structure of the Intermetallic Compound $\text{Mg}_2\text{Cr}_3\text{Al}_{11}$

A TERNARY intermetallic phase with the approximate composition MgCrAl_2 , called the *H*-phase, was observed by Erdmann-Jeanitzer¹ in his examination of the magnesium-chromium-aluminium system. Little, Axon and Hume-Rothery² found that the magnesium content of the *H*-phase can vary considerably, and that, furthermore, zinc is soluble in the phase to some extent. Crystals extracted from two ternary alloys were found on analysis to have the compositions $\text{Mg}_2\text{Cr}_{2.1}\text{Al}_{11.1}$ and $\text{Mg}_2\text{Cr}_{2.01}\text{Al}_{11.1}$, and those of an *H*-phase sample containing zinc were

found to have the composition $\text{Mg}_2\text{Cr}_{1.3}\text{Zn}_{0.4}\text{Al}_{11.1}$. The results of micrographic investigation indicated that the range of composition extends at least from $\text{Mg}_2\text{Cr}_2\text{Al}_{11}$ to $\text{Mg}_2\text{Cr}_{1.2}\text{Al}_{11}$.

A report of a structure determination of the *H*-phase is given below. The determination is based on single-crystal X-ray diffraction data (copper $K\alpha$ radiation). The crystals used were isolated from an alloy containing a small amount of zinc (approximately 1.5 per cent by weight). A final refinement of the structure parameters is being made.

The space group is $O_h^1 - Fd\bar{3}m$, $a_0 = 14.55$ Å. The ideal composition of the crystals derived from X-ray data was found to be $\text{Mg}_2\text{Cr}_2\text{Al}_{11}$. The density of the crystals was found to be 2.80 gm./cm.³ by use of the flotation method. The calculated density is 2.86 gm./cm.³.

With the notation of the International Tables for X-ray Crystallography³ the structure may be described as in Table 1.

Table 1

No. of atoms	Position	Kind	Ligancy
96	f $8, 8, 8$, etc. $s = 0.067$; $s = 0.298$	Al	12
48	f $8, 0, 0$, etc. $s = 0.134$	Al	12
16	d $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$, etc.	Mg	14
8	b $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$, etc.	Mg	16
16	c $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$, etc.	Cr	12

The aluminium and chromium atoms have ligancy 12, and the magnesium atoms, which are larger, have ligancy 14 or 16. The bond distances are approximately $\text{Mg-Mg} = 3.15$ Å, $\text{Mg-Al} = 3.10-3.22$ Å, $\text{Al-Al} = 2.72-2.90$ Å, $\text{Al-Cr} = 2.58-2.78$ Å.

The *H*-phase represents a new structure type. At $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$ there is a group of six aluminium atoms (48 *f*) located at the vertices of a regular octahedron. Outside this group of atoms there are four chromium atoms at the vertices of a regular tetrahedron. Each of these atoms is shared between two such 10-atom complexes. At $(\frac{1}{2}, \frac{1}{2}, \frac{1}{2})$ there is a magnesium atom (8 *b*) surrounded by a shell of twelve aluminium atoms (96 *g*). This shell may be described as a truncated tetrahedron, bounded by four nearly regular hexagons and four equilateral triangles. Out from the centres of the four hexagons of this shell there are four magnesium atoms located at the vertices of a regular tetrahedron. These magnesium atoms are shared by two such 17-atom complexes. The structure can thus be described as consisting of the two different kinds of groups, with each group surrounded by four groups of the same kind and four groups of the other kind. The packing of atoms is very good.

While the X-ray diffraction data suffice for determining which positions are occupied by chromium atoms, the distribution of magnesium and aluminium atoms over the occupied atomic positions has to be found by other means. Packing considerations indicate that the magnesium atoms are in the positions given above. This arrangement agrees fairly well with the composition found by chemical analysis² and is the most reasonable one if the structure is completely ordered with respect to the magnesium atoms.

The analyses of various *H*-phase samples² indicate some variation in the atom percentage of magnesium. In view of the considerable difference in size of the magnesium atoms and the chromium and aluminium atoms this variation is hard to explain. It seems

possible that the chemical analyses are inaccurate by amounts sufficiently large to resolve this difficulty.

At the present stage of the parameter refinement it is impossible to exclude the possibility of disorder of chromium and aluminium atoms. In view of the short nearest-neighbour distances around position 16c it is, however, likely that these positions are occupied exclusively by chromium atoms. In the position 96g disorder cannot be excluded, but the Fourier projection (xy) indicates that these positions are occupied nearly exclusively by aluminium atoms.

The work on the H -phase is being continued. Emphasis will be laid on the investigation of the range of composition of the H -phase in the ternary as well as in the quaternary system.

I wish to thank Prof. Linus Pauling for his interest in this work and for valuable discussions. I am also indebted to Dr. Gunnar Bergman for many valuable discussions and suggestions, and to Statens naturvetenskapliga forskningsråd in Stockholm for a travel grant to California.

This work was done under Contract No. N6-onr-24432 between the California Institute of Technology and the Office of Naval Research.

Ionization and Excitation of Mercury Vapour by Positive Ion Impact

THE direct ionization of atoms by impact of positive ions, as postulated by Townsend in his theory of the electrical breakdown of gases, has been the subject of much controversy¹. Direct observation of ionization by ion impact is difficult, because the effect is small and is easily obscured by ionization due to secondary electrons or to photo-ionization by the short-wave radiations emitted by the source of ions. However, there is a growing body of evidence² that positive ions with energies of a few hundred electronvolts can ionize gases by impact. Recent work by Llewellyn-Jones and his co-workers in Swansea³ has revived belief in the validity of the Townsend hypothesis.

We have used a Geiger counter, with highly photo-sensitive cathode, to study the radiations emitted when potassium ions bombard mercury vapour. Effects due to electrons have been eliminated by use of appropriate electron traps, while the fact that the radiations come from the mercury has been verified by freezing out the vapour. The curves in Fig. 1 show how the counts due to the radiation vary with the energy and intensity of the beam of potassium ions. The Geiger counter was sheathed with glass, so that no short-wave ultra-violet radiation was detected.

It is seen that radiation was first detected at a bombarding energy of about 220 eV. and that the intensity, which is proportional to the beam current, increased monotonically with energy. Jones⁴ has shown that potassium ions of energy 300 eV. and above excite most strongly the ultra-violet 2537 Å.

Fig. 1. Energy of positive ions: (1) 250 V.; (2) 550 V.; (3) 900 V

line of mercury and that the intensities do not change much in the energy-range 300–800 eV. We conclude that the radiations detected by us are largely recombination spectra following ionization of the mercury atoms by ion impact.

These observations are being extended and will be published in detail elsewhere.

Clinical and Metallurgical Observations on the Corrosion of Stainless Steel Screws used in Orthopaedic Surgery

WE wish to comment briefly on the recent article by Bowden, Williamson and Gowans Laing¹ in which they direct attention to the transfer of metal from the screw-driver to the head of an orthopaedic screw. While we are completely convinced by their experimental work on metallic transfer, we doubt the importance of this particular effect in promoting electrolytic corrosion of orthopaedic components. Particularly we would point out that the transfer of 65 μ m. of anodic material to the head of the screw would allow the corrosive dissolution of that 65 μ m. of material from the head of the screw, whereas clinical observation indicates that it is not the screw head which suffers the most serious corrosion. With stainless steel material the significant destructive corrosion, as distinct from superficial tarnishing, is concentrated at regions of contact between two metal components or between metal and bone. Moreover, in certain cases, as much as 1 gm. of metal may be dissolved away from one nut or screw. Corrosion at such regions obviously destroys the mechanical rigidity of the fixation. A more detailed account of

the theory of the distribution of destructive corrosion in orthopaedic screws is in course of preparation.

¹ Bowden, F. P., Williamson, J. B. P., and Laing, P. G., *Nature*, 173, 520 (1954)

It may be useful to describe in a little more detail the nature of the welded particles of metal which are transferred from one surface to the other. Fig. 1 shows two taper sections, taken by Dr. A. J. W. Moore, illustrating typical fragments of copper which were welded on to a mild steel surface after the copper had slid over it once. There is evidence that, with most metals, the particles penetrate the oxide layer and adhere to the underlying metal. Since the resistance to corrosion of a stainless steel is due to the protection of its superficial oxide layer, the dissolution of these embedded foreign fragments, if they are anodic, may lead to a serious breakdown of the oxide layer and to the onset of continuing corrosion. If the adherent particles are cathodic (with these stainless steels the relative electrode potential is very dependent on the extent to which the oxide layer is disturbed and also on the surrounding medium; see, for example, Evans¹) continuing corrosion may again result. It would be unwise to assume that the transfer of 65 μ m. of material, anodic or cathodic, to the screw head would allow the corrosive dissolution of only 65 μ m. from the head.

Fig. 1. Taper section photographs illustrating adherent metal fragments of copper (dark) on to steel. Note the rupture and penetration of the steel surface. C, copper; P, ferrite; P, pearlite

The particular screws and plates associated with the tissue reaction described in our article did not show any signs of gross destructive corrosion. It is well known that the corrosion can be influenced by a mechanical deformation of the surface, by differential aeration, by fretting corrosion and by changes in the pH value of the medium caused by sepsis. The relative importance of the different factors has been discussed by a number of workers.

Our experiments have indicated that there is another factor which should be considered—the transfer of metal from the tools. The presence of these adherent fragments of foreign metal is a possible cause of the observed tissue reaction adjacent to the regions handled, and the experiments suggest that attention should be given not only to the buried metals but also to the tools used to insert them.

F. P. BOWDEN

J. B. P. WILLIAMSON

Physics and Chemistry of Surfaces,
Department of Physical Chemistry,
University of Cambridge.

In our article we were not discussing heavy localized destructive corrosion and superficial tarnishing of orthopaedic components, since these are rarely found except when non-identical metals have been inserted or when sepsis has occurred. In all the cases we have examined there was no obvious sign of corrosion, but examination of the biopsy specimens showed that cellular reaction and iron infiltration had occurred in the tissue adjacent to the buried metals. This reaction is greatest near the screw and bolt heads, which have been handled by tools, and least near unhandled regions of the metal. It occurs in the absence of any concentrated destructive corrosion in the region of contact between the two components or between metal and bone.

The mechanical rigidity of the fixation will inevitably be destroyed within a month by the loosening of the screws in the bone. Evidence suggests that this is due, not to corrosion of the metal but to bone absorption caused by the pressure of the screw. Such absorption is known to be produced in other circumstances where no corrosion is possible, for example, where pressure is exerted by a locally enlarged artery.

The physical experiments have shown that localized transfer of a different metal can occur. Since this is a potential source of corrosion and of cellular reaction it is very important, from the surgical point of view, that it should receive due attention and, if possible, be avoided until our understanding of these physiological processes is more complete.

Structure of Cobalt Complexes with Salicylideneanilines

THE structures of cobalt inner complexes with salicylideneanilines have not been determined, whereas the planar form of copper complexes of this type has been established beyond doubt by the isolation of *cis* and *trans* isomers¹ and by X-ray investigation². A difference in reactivity has now been observed between copper and cobalt ions with various salicylideneaniline bases which suggests a tetrahedral structure for the cobalt complexes. Attempts have been made to prepare complexes of the type *bis*-(salicylideneaniline)cobalt with bases containing aromatic amines bearing substituents in the *ortho*, *meta* and *para* positions. The compounds prepared are tabulated below together with the corresponding copper complexes previously prepared³.

The method of preparation has already been outlined⁴. It appears that cobalt shows a reluctance to form complexes with bases bearing bulky *ortho* substituents in the aniline ring, whereas copper forms complexes easily with *ortho*-, *meta*- or *para*-substituted amines. The one exception has been the *o*-anisidine cobalt complex. For those cases where cobalt failed to give the expected product, dark red

+ Complex of expected type isolated.

— Complex of expected type not isolated.

¹ Evans, U. R., "Metallic Corrosion, Passivity and Protection" (Arnold, 1946).

solutions resulted on mixing the reactants just as in the cases where complexes were isolated. However, on cooling the former solutions, small amounts of red oils or tars were obtained in the cases of the *o*-toluidine and α -naphthylamine reactions and orange-red solids of indeterminate composition with *o*-chloroaniline and *o*-nitroaniline. The red oils, when dissolved in organic solvents and the solutions carefully evaporated, yielded only unchanged base and further tarry products. All other means of inducing crystallization of these products, for example, freezing and use of mixed solvents, were unsuccessful. The addition of sodium acetate or hydroxide to the reaction mixture was likewise unsuccessful.

It is therefore suggested that *ortho* substituents on the aniline ring can exert steric hindrance to stable complex formation in the case of cobalt, whereas this effect is either non-existent or much lessened in the case of copper.

Stackelberg⁴ has confirmed the planar configuration for *bis*(salicylideneaniline)copper by X-ray analysis, showing that the four donor atoms are co-planar with the copper. However, he observed that the aniline rings were tilted out of the plane of the donor atoms. Other evidence as to a general *trans* relationship of *R* and *R'* in salicylideneaniline bases ($R-CH=N-R'$) may be inferred from the studies of Hilbert, Liddell and Wulf⁵ on hydrogen bonding in such compounds and from the dipole moment measurements of Le Fevre and De Gaouac⁶. Thus, one may assume that the structure of the salicylideneaniline part of the complexes will be the same no matter what the arrangement of donor atoms about the central ion, that is, the substituted aniline ring will in each case be orientated at an angle to the plane of the salicylidene ring system. The construction of planar models of copper and cobalt complexes indicates that large *ortho* substituents such as $-OH$, or Cl — still permit considerable freedom of rotation of the aniline ring about the N—O linkage, although complete freedom of rotation could only be obtained through straining the model considerably. For a tetrahedral arrangement of ligands about the cobalt ion a greatly increased restriction is placed on the rotation of the aniline rings if co-ordination is to occur. *Meta* or *para* substituents appear to cause little or no restriction to rotation of the aniline ring for either planar or tetrahedral arrangements. Thus, with the knowledge that *bis*(salicylideneaniline)copper and presumably all other analogous copper complexes have planar structures, one may suggest this reported failure to isolate analogous cobalt complexes with *ortho* substituents provides indirect evidence of the tetrahedral formulation for the salicylideneaniline complexes of this element.

The isolation of the stable *o*-anisidine complex of cobalt seems to negate this hypothesis until one realizes that the methoxyl group may act as a co-ordinating centre and hence may enhance chelation rather than oppose it. The resulting complex may be pictured as possessing a distorted octahedral configuration.

A Temperature-limiting Mechanism in the Thermal Decomposition of Ammonium Nitrate

WHEN ammonium nitrate is heated, two of its main reactions are dissociation and decomposition according to the following equations:

Ray and Jâná² have shown that reaction 1 is substantially complete in the vapour phase at low pressure. Reik³ has found the vapour pressure of the products to be 11 mm. at 210°C . From these values, the vapour-pressure curve for ammonium nitrate was estimated.

Despite the exothermic nature of reaction 2, the behaviour of unconfined ammonium nitrate on heating is not that of a typical exothermic reaction, in that it shows little tendency toward self-acceleration or even toward continued reaction after the source of heat is removed. This observation may be explained by postulating that, in decomposing ammonium nitrate, the gaseous products of reaction 2 issuing at the ambient pressure are saturated with the products of reaction 1 at their vapour pressure. When the temperature and, therefore, the dissociation pressure become sufficiently high, all the heat generated by the decomposition will be absorbed by the endothermic dissociation reaction. The reacting melt will then tend to seek a particular limiting temperature which is a function of the external pressure and of the heat supplied to, or removed from, the melt by its surroundings.

For the adiabatic case, a heat balance on the reacting mass leads to the equation:

$$P = \left[1 + \frac{3}{2} \left(\frac{\Delta H_1}{\Delta H_2} \right) \right] p, \quad (3)$$

where P is the external pressure, p is the dissociation pressure of ammonium nitrate at the temperature in question, and ΔH_1 and ΔH_2 are given above. Based on an estimate of the dissociation pressure versus temperature curve, the limiting temperature will be about 296°C . at an ambient pressure of one atmosphere.

Equation 3 was tested experimentally by electrically heating a sample of ammonium nitrate in an insulated vessel and measuring the reaction temperature under adiabatic conditions at various pressures. At one atmosphere, the steady-state temperature was 292°C . The equation gives reasonably good predictions of the limiting reaction temperature over a pressure range of 0.02–2.0 atmospheres.

The rate of reaction can be estimated from an experiment which illustrated the temperature-limiting effect. Liquid ammonium nitrate, preheated to above 250°C ., poured into a preheated Dewar flask shows an accelerating rate of heating up to the limiting temperature, where with the evolution of copious white fumes of sublimed ammonium nitrate the sample continues to decompose until it is exhausted. By weight loss, the reaction-rate is found to be first order; at 286°C . the half-life is about five minutes.

This work, which will be reported elsewhere in greater detail, was performed under the auspices of the United States Coast Guard and the Advisory Committee on Hazards of Ammonium Nitrate Transportation of the National Research Council. Per-

mission to publish this article has been granted by the United States Coast Guard; but neither of the sponsoring parties necessarily approves the technical opinions or conclusions.

Enzymatic Formation of 3 α -Hydroxysteroids

BUTENANDT¹ isolated the first crystalline androgen, androsterone, from human urine and determined its structure. The 3 α -hydroxysteroids, androsterone (androstan-3 α -ol-17-one) and etiocholan-3 α -ol-17-one, are the principal metabolites of endogenous androgens and of administered testosterone². The enzymatic mechanisms responsible for these interconversions have only been partly identified, and in particular the direct enzymatic interconversion of 19-carbon 3-ketosteroids and 3 α -hydroxysteroids has not been previously demonstrated. We wish to describe the isolation and purification of a steroid-induced (adaptive) 3 α -hydroxysteroid dehydrogenase of bacterial origin which catalyzes freely reversible interconversions of the type:

where DPN⁺ and DPNH refer to oxidized and reduced diphosphopyridine nucleotides respectively.

Cell-free extracts of a *Pseudomonas* sp. capable of growing on testosterone or related 19-carbon steroids³ contain a β -hydroxysteroid dehydrogenase⁴ which catalyzes reversible oxidations of 8 β and 17 β hydroxyl groups to the respective keto forms. The extracts containing the β -hydroxysteroid dehydrogenase also contain a DPN⁺-linked 3 α -hydroxysteroid dehydrogenase. Both enzymes are induced in response to the presence of testosterone or similar steroids in the growth medium. The 3 α -hydroxysteroid dehydrogenase has been purified some 30–50-fold over original extracts and virtually separated from β -hydroxysteroid dehydrogenase by the following steps: (1) ammonium sulphate precipitation at 45–55 per cent saturation; (2) precipitation of nucleic acids with protamine sulphate; (3) refractionation with ammonium sulphate (45–50 per cent saturation) in the presence of 0.005 *M* DPN⁺; (4) adsorption of impurities by calcium phosphate gel (pH 5.8).

The enzyme activity has been measured spectrophotometrically by observing the rate of appearance of the absorption band of DPNH at 340 m μ (Fig. 1, A)

Fig. 1. (A) Conversion of androsterone to androstane-3,17-dione. Spectrophotometric measurement of reduction of DPN⁺ with time in a 3.0-ml. system containing: 100 μ M pyrophosphate buffer, 0.6 μ M DPN⁺, 25 μ gm. androsterone, and 7.2 μ gm. enzyme protein. Final pH 9.50; 25° C. 1.0 cm. light-path cells. (B) Conversion of androstane-3,17-dione to androsterone. Spectrophotometric measurement of oxidation of DPNH in a 3.0-ml. system containing: 100 μ M orthophosphate buffer, 0.25 μ M DPNH, 25 μ gm. androstane-3,17-dione, and 7.2 μ gm. enzyme protein. Final pH = 5.74; 25° C. 1.0 cm. light-path cells

or the rate of disappearance of the absorption of DPNH (Fig. 1, B) at 25° C. and appropriate pH. The enzyme is stable for at least several weeks at 0° in 0.005 *M* DPN⁺ solution; but is much less stable in the absence of its coenzyme. Free sulphhydryl groups appear to be necessary for activity inasmuch as the enzyme is strongly inhibited by 8×10^{-4} *M* mercuric ion, 3×10^{-3} *M* *p*-chloromercuribenzoate, 3×10^{-4} *M* ferrous ion and 3×10^{-4} *M* cupric ion.

The velocity of androsterone oxidation rises with increasing pH, whereas the reverse reaction is favoured by low pH. The equilibrium constant $K = [\text{androsterone}] [\text{DPNH}] / [\text{androstane-3,17-dione}] [\text{DPN}^+]$ is 0.13 at pH 7.4 and 25° C., and there is a linear relation of unit slope between $\log_2 K$ and the pH. The affinity between androsterone and the enzyme is extremely high. The accurate measurement of the Michaelis constant for this substrate presents technical difficulties, but is of the order of 1×10^{-4} *M* at pH 9.2 and 25° C. Under similar conditions the Michaelis constant for DPN⁺ is 1×10^{-4} *M*.

Specificity studies indicate that 3 α hydroxyl groups of both the androstane (A/B ring *trans*) or etiocholan (A/B ring *cis*) series are oxidized, but that other hydroxyl groups in positions such as 8 β , 6 β , 11 α , 11 β , 16 α , 17 α , 17 β and 21 are not oxidized. Conversely, only 3-ketosteroids are reduced by the enzyme to the corresponding 3 α -hydroxysteroids. If the 3-keto group is associated with either a $\Delta^{1,2}$ or a $\Delta^{4,5}$ double bond, the compound is not reduced under the conditions studied.

The products of the reaction in either direction have been identified by paper chromatography. Under suitable conditions (cf. Fig. 1) the equilibrium may be so shifted that the reaction is quantitative in either direction. This has made it possible to assay and identify specifically 3α -hydroxysteroids and saturated 3-ketosteroids in quantities of 1 microgram or less. The enzyme also provides a one-step stereo-specific synthesis of androsterone from androstane-3,17-dione.

The equilibrium constants of α and β hydroxysteroid dehydrogenase-catalysed reactions are such that at pH 7.4 the oxidation of 17 β -OH groups and the reduction of the 3-keto groups to 3α -OH groups are favoured. These enzymatic mechanisms may be responsible for two of the three postulated steps in the conversion of testosterone to androsterone and etiocholan- 3α -ol-17-one. Although the enzyme responsible for hydrogenation of the double bond remains unidentified, this reaction presumably precedes the reduction of the 3-keto group. Preliminary experiments have demonstrated the presence of 3α -hydroxysteroid dehydrogenase in mammalian tissues.

This work has been supported by grants from the American Cancer Society, recommended by the U.S. National Research Council Committee on Growth, and from the Jane Coffin Childs Memorial Fund for Medical Research. Full acknowledgments for gifts of steroids will be made elsewhere.

Enzyme Inhibition

Katchalski, Berger and Neumann¹ have recently described the inhibition of pepsin by polylysine, polyornithine and poly-p-amino-phenylalanine. We would suggest that this is not an isolated effect but is an example of a widespread non-specific action of high molecular weight polyelectrolytes on many enzymes.

During recent years a number of references to such action have accumulated. For example, Hahn and his collaborators² have described the inhibition of hyaluronidase by polymers prepared from formaldehyde and various hydroxybenzoic acids; another team in Sweden³ has studied the inhibition of this enzyme, and of acid and alkaline phosphatases, hexokinase, urease and β -amylase, by phosphate polymers of various aromatic hydroxy and amino compounds. Heparin has been shown to inhibit hyaluronidase⁴, ribonuclease, deoxyribonuclease⁵ and α -amylase⁶; nitrated and acetylated hyaluronic acid⁷, cellulose and chitin sulphates⁸ inhibit hyaluronidase; phenolsulphonic acid-formaldehyde polymers inhibit hyaluronidase⁹, nucleases and α -amylase; polystyrene sulphonate, if of sufficient molecular size, also inhibits hyaluronidase (unpublished observa-

tions). The only characteristics which these inhibitors, with their varied chemical composition, appear to have in common are (a) high molecular weight, (b) polyanionic structure, and it seems probable that all substances with these two properties will exert some degree of inhibition against certain enzymes. It will be interesting in due course to discover the manner in which the potency varies with molecular size and with both proportion and type of anionic groups. We should mention, however, that a third feature has been suggested¹⁰ as necessary for inhibition of this kind, namely, that the molecules should be filamentous, since it is claimed that sulphonated glycogen and amylopectin, which are globular in form, do not inhibit hyaluronidase.

In view of the obvious importance of this general effect, it might be useful to introduce the term 'macroanion' for this class of substance and thus to refer to 'macroanionic inhibition'.

The work of Katchalski, Berger and Neumann¹ now suggests that a similar class of high molecular weight polycationic inhibitors ('macroocations') may also exist, these acting possibly upon a different group of enzymes.

Heparin (a macroanion) reverses this macrocationic inhibition of pepsin¹, in a manner similar to the reversal of the macroanionic inhibition of hyaluronidase by the macroocations protamine and methyl-gelatin⁴. Both effects must be due to some form of macroanion-macroocation interaction. A similar interaction may be involved also between enzymes and inhibitors of the type considered here and indeed in certain enzyme-substrate reactions themselves. Further study of the susceptibility of enzymes to macroanionic and macroocationic inhibition in concert with their chemical and physico-chemical properties may usefully further our understanding of enzyme action and inhibition both *in vivo* and in isolated systems.

Fractional Precipitation of Nucleic Acid

MILVILLE *et al.*¹ have recently used turbidity measurements to follow the fractional precipitation of high polymers from solution. The turbid suspensions were found to be stable if very dilute polymer solutions were used. Nucleic acids are precipitated from aqueous solution by acids, cationic detergents, positively charged polyelectrolytes and alcohol. Stable suspensions are produced when hydrochloric

acid solution is used as the precipitant for very dilute nucleic acid solutions, but the use of alcohol rapidly coagulates the precipitate. Solutions of cetyltrimethylammonium chloride give results similar to hydrochloric acid but the suspensions tend to flocculate near the end-point of the precipitation.

Several samples of sodium deoxyribonucleate (DNA) prepared by different workers and from different sources were precipitated from aqueous solution by the gradual addition of 0.5 *N* hydrochloric acid and the turbidity of the solutions followed (Fig. 1). Within limits the DNA concentration did not affect the precipitation curves, and all the DNA solutions precipitated were 0.0037 per cent except those of wheat germ DNA. Reproducibility was good except for a commercial sample of calf thymus DNA supplied by Messrs. British Drug Houses, which probably consisted of degraded material extracted by acid and alkali treatment. Under the microscope ($\times 400$) the precipitates appeared as coacervate drops about 3μ in diameter which in some cases seemed to solidify on standing.

Degraded samples of DNA obtained by boiling aqueous solutions for different times were precipitated in the same way. Fig. 2 shows that DNA is more easily precipitated by hydrochloric acid the more it is degraded. It seems that in the precipitation of DNA by ionic precipitants the low molecular weight material is precipitated first, in contrast to the action of non-solvents on organic solutions of uncharged polymers. It will be interesting to see if this behaviour is typical of polyelectrolytes in general. The presence of sodium chloride also facilitates the precipitation (Fig. 2), probably due to the binding of Na^+ by the DNA. The hydrochloric acid precipitant does not significantly degrade the DNA (at least not sufficiently to affect the precipitation) since a sample which was made 0.2 *M* in hydrochloric acid and neutralized with sodium hydroxide gave precisely the same precipitation curve as a sample dissolved directly in 0.2 *M* sodium chloride (Fig. 2). In contrast, a sample treated with alkali and then neutralized by acid showed considerable degradation. Fig. 2 shows the effect of mixing a high molecular weight and a degraded sample; the same type of curve is still obtained with no extra inflexion.

The breaks in the curves in Fig. 1 at approximately 90 per cent turbidity for DNA from calf thymus suggest that there are two kinds of solute particles in these solutions. Two widely separated fractions of the same species will not produce a break in the

Fig. 2. Effects of salt, degradation and mixing high and low molecular weight samples. 1, Calf thymus DNA, *S*, in aqueous solution; 2, *S* in 0.06 *M* NaCl; 3, *S* in 0.2 *M* NaCl; *G*1(1) in 0.2 *M* NaCl; *G*1(1) made 0.2 *M* in HCl then neutralized by NaOH; 4, *A*1, untreated; 5, *A*1 boiled 8 min.; mixture of equal quantities untreated *A*1 and *A*1 boiled 5 min.; 6, *A*1 boiled 30 min.

curve as shown by the curve for the mixture in Fig. 2. This is in agreement with the suggestion of Sadron³ that some of the properties of DNA solutions are consistent with the presence of two kinds of particles, one type being significantly larger than the other. All the samples of DNA from calf thymus examined showed this effect but those from wheat germ and herring sperm did not. Cecil and Ogston⁴ found that thymus DNA which had been brought to pH 3.5 sedimented as two components. In other respects the general shape of the precipitation curves does not clearly indicate whether the DNA is polydisperse since the mixed sample (Fig. 2) gave the same shaped plot as all the others. Attempts to separate useful quantities of turbid precipitates from these very dilute solutions have not so far been successful.

Measurements of the extinction angles at low gradients in streaming birefringence were made and values of $(\tan \alpha)_0$ calculated. These results show that the amount of hydrochloric acid necessary to effect precipitation is a function of the molecular size of the DNA. The table shows that the value of $\log_{10}(\tan \alpha)_0$ is proportional to the quantity of hydrochloric acid necessary to precipitate 50 per cent of the DNA for the untreated samples. This may therefore be used as a rapid method of comparing the molecular sizes of different samples of DNA.

$\log_{10}(\tan \alpha)_0$	0.40	0.08	-0.06	-0.15	-1.35
Vol. HCl (c.c.) producing 50 per cent turbidity	4.73	4.40	4.04	3.80	2.20

Action of Coumarin Anticoagulants on a Possible New Serum Clotting Factor

THERE have been several reports in recent years suggesting that a blood coagulation factor other than factor VII or prothrombin may be affected by the administration of coumarin anticoagulant drugs. Dam (personal communication, 1952) has detected such a factor in his experimental work in chickens, and more recently Koller¹ described a new factor, deficient in the blood of patients receiving coumarin anticoagulants, and unaffected by vitamin K.

Using serum from coumarin-treated patients as a source of factor VII and Christmas factor in the blood thromboplastin generation test², we have found that thromboplastin generation may be impaired when the corresponding one-stage test of Quick, which measures principally factor VII, is normal or very nearly so (Fig. 1). This has occurred both early in treatment before the one-stage test has lengthened, and on cessation of treatment soon after it has returned to normal. The same observation has been made after a single dose of a coumarin drug insufficient to make any change in the one-stage test. The sera from these patients gave normal blood thromboplastin generation in mixtures of platelets and plasma treated with aluminium hydroxide when they were not under the influence of the drug.

We have hesitated to ascribe these results to action on a new factor because the possibility existed that they might be due to an effect on Christmas factor, or that the thromboplastin generation test was a more sensitive index of factor VII deficiency than the one-stage Quick test. We now have carried out the thromboplastin generation test using more than two hundred samples of coumarinized serum in mixtures of normal platelets and plasma treated with aluminium hydroxide, and find that there is no apparent correlation between the results and moderate factor VII deficiency as indicated by the Quick test³. Moreover, we have found a similar phenomenon in patients with hepatocellular disease, but not so far

Fig. 1. Blood thromboplastin generated from the same mixture of platelets and plasma treated with aluminium hydroxide using normal serum (upper curve), and sera from two patients 48 hr. after a single dose of 200 mgm. naphthylhydroxycoumarin, when Quick test was normal.

Fig. 2. (1) Normal thromboplastin generation using serum from patient with hepatitis: Quick test, 18 sec. (control 11 sec.). (2) Impaired thromboplastin generation three days later, using serum from same patient: Quick test, 16 sec. (control 12 sec.).

in obstructive jaundice. Fig. 2 shows normal thromboplastin generated in a mixture of platelets and plasma treated with aluminium hydroxide by the serum of a patient with infective hepatitis at a time when his Quick test was prolonged to 18 sec. (control 11 sec.) owing to deficiency of factor VII. Three days later his serum gave impaired thromboplastin generation, although his Quick test was now 15 sec. (control 12 sec.).

There is some evidence, therefore, in support of the suggestion by Koller that an additional factor is present in serum, though to our knowledge the behaviour of Christmas factor during coumarin administration or in liver disease has not yet been sufficiently studied to exclude deficiency in this factor as a cause of these findings.

Unsuccessful Attempt to demonstrate a Paralytic Factor in Serum of Myasthenia Gravis Patients

So far there has not yet been any clear confirmation of the experiments of Wilson and Stoner¹, Adler² and others which were thought to have demonstrated the presence of a curare-like substance in the serum of myasthenic patients. As the presence of such a circulating paralytic factor cannot explain the abnormal reaction of myasthenic patients when injected with decamethonium³, we thought it desirable to attempt further confirmation of the results obtained by Wilson and Stoner.

We have had an opportunity of examining the serum of three patients who were suffering from serious myasthenia. Treatment was stopped 24 hr. before the experiments and the serum was examined within two hours after bleeding. The following experiments were carried out.

(1) Three dogs were injected intravenously with the serum (10, 40 and 60 ml.). They were then trotted for about half an hour. No abnormal fatigue could be ascertained.

(2) Fifteen cats were anaesthetized with luminal, whereupon the peripheral end of the severed sciatic nerve was stimulated with square-wave impulses. We applied tetanic stimulation with different frequencies up to 300 stimuli per second and single twitch stimuli (frequency: 54 impulses in 10 min.). The isotonic contractions of the tibialis muscle were recorded. The serum was injected intravenously (5-10 ml.), intramuscularly into the tibialis muscle (3-5 ml.) and intra-arterially into the art. femoralis (8 ml.). The serum could not be shown to cause a decrease of the contractions.

(3) Twenty rats were anaesthetized with urethane, and the peripheral end of the severed sciatic nerve was stimulated with square-wave impulses. Only single-twitch stimuli were applied, the frequency being 54 impulses in 10 min. The serum was injected intravenously (5 ml.). In this experiment, too, we failed to find any decrease of the isotonic contractions (that is, of the m. gastrocnemius).

(4) 5 ml. of serum was added to the Tyrode's solution of an isolated phrenic-diaphragm preparation of a rat as recommended by Bülbirg. The bath contained 100 ml. The serum had no effect on the contractions of the diaphragm.

(5) To the Ringer's solution of an isolated rectus abdominis preparation of a frog we added 2 ml. of serum, the bath containing 15 ml. Contractions of the muscle were evoked with 5 μ gm. acetylcholine. The serum of the patient caused a marked decrease of the muscular contractions, but it was no greater than that brought about by the control serum. So we may ascribe this decrease of the contraction to the cholinesterase of the serum.

(6) 3 ml. of serum was injected into a lymph space (sacculus thoracis) of a frog. During the following two hours, no abnormal flaccidity of the muscles could be observed.

(7) 7 ml. of serum of a myasthenic patient was injected into the m. flexor digit. subl. of a normal volunteer and of another patient. There was no objective decrease of muscular strength.

Although our experiments cannot be regarded as a definite proof against the theory that blood of myasthenic patients contains a substance which resembles curare, we believe that this conception appears less likely in the light of our results.

A Remarkable Family with the Rare Human Isoantibody Anti- T_j^a In Four Siblings: Anti- T_j^a and Habitual Abortion

RECENTLY, Isaki and Masaki¹ reported what they believed to be a new isoagglutinin in the serum of a 27-year old patient who had six pregnancies all ending in abortions at two to five months. The serum of this group A, Rh-positive patient agglutinated the blood of each one of a hundred random bloods of groups O and A, independent of their Rh status. The serum, however, failed to react with its own red cells and the red cells of three out of four siblings. On the basis of absorption experiments, we believed that we were dealing with a single antibody which appeared to be different from anti-k (anti-Cellano) and anti-e, both of which give very high incidence of positive reactions.

Blood specimens (serum and clots) of the propositus and her three compatible siblings were sent by air-mail to the Ortho Research Foundation for identification of this unusual antibody. The sera and three of the clots were in excellent condition when received, but the blood of the propositus was completely hemolyzed.

On testing the four sera with fifty random group O bloods, positive reactions were obtained with all bloods. Each of the four sera, however, failed to react with the group O red blood cells of the Virginia patient in whose serum Levine *et al.*² described the first example of anti- T_j^a . Furthermore, the red cells of the three siblings failed to react with their own four sera and with three stock samples of anti- T_j^a . (In testing the two group A siblings, the activity of anti-A was neutralized by the addition of group A specific substance.) Thus, this unique Japanese family provides four additional examples of anti- T_j^a to the four already published and an additional five identified by one of us (P.L.). In all, there are now thirteen examples of anti- T_j^a in seven families scattered over five continents³.

The significant data in the Japanese family follow:

					Reaction with anti- <i>T₂</i> ^a	} parents not related to each other
Father Mother	O died	MN	R ₁ r		+	
Sib. 1	♂	O	MN	R ₁ R ₂	+	6 miscarriages unmarried
Sib. 2	♀	A	MN	R ₁ R ₂	0	
Sib. 3	♀	A	M	R ₁ R ₂	0	
Sib. 4	♂	O	MN	R ₁ R ₂	0	
Sib. 5	♂	O	M	R ₁ R ₂	0	
150 random bloods					+	
Red cells of Virginia patient					0	

The red cells of siblings 3, 4 and 5 were R_y^a positive and negative for $Kell$, Le^a and Jk^a . The antibody in each of the four siblings gave titres of 1/1 to 1/2 at 37° and 1/4 to 1/16 at 18° C. At 37° C. only traces of hemolysis were observed, but this may be due to deterioration of the complement in the interval of fourteen days between the shipment from Japan and the tests in Raritan, New Jersey.

In the absence of a history of antigenic stimulus by a transfusion, it may be assumed that anti- T_j^a is a naturally occurring antibody, which is regularly present if the red cells lack the very frequent blood factor T_j^a . In each case, the individual is of the very rare genotype $T_j^b T_j^b$ which determines the presence of anti- T_j^a —a state of affairs which is quite analogous to the distribution of anti-A and anti-B in the scheme of the four blood groups.

Levine and Koch⁴ have shown that the specificity of anti- T_j^a is distinct from that of the anti-H produced

¹ Wilson, A., and Stoner, H. B., *Quart. J. Med.*, 13, 1 (1944).

² Adler, H., *Deut. Z. Obitrerie*, 860, 614 (1938).

by the three group *O*, *Le(a +)*, *Tj(a +)* Indians described by Bhatia *et al.*⁴. This variety of anti-*H* resembles anti-*Tj*⁵ in its regular occurrence with a specific and very rare genotype and its reactions with all random bloods tested. Of the thirteen individuals producing or possessing anti-*Tj*⁵, nine are in group *O* and four in group *A*, and with one exception all those tested with anti-*Le*⁶ are negative.

The occurrence of six consecutive miscarriages of the propositus of the Japanese family is very remarkable, and their etiological relationship to the presence of anti-*Tj*⁵ is suggested by a history of miscarriages in each one of eleven pregnancies of three patients (4, 4 and 3 respectively) studied by Zoutendyk and Levine⁵, Hirszfeld and Grabowska⁶ and Levine *et al.*⁷. If one includes the Australian patient with one miscarriage (Walsh and Koopstzoff⁸), there is a total of eighteen miscarriages with no full-term pregnancies in five patients with anti-*Tj*⁵, all of whom are in the child-bearing age. The only exceptions are the first two Virginia siblings aged sixty-six and forty-three, in one of whose sera anti-*Tj*⁵ was first identified as a new antibody. Although not found in the younger sibling in 1951, anti-*Tj*⁵ was demonstrated in 1953. The two siblings had eleven (four and seven respectively) full-term, normal and successful pregnancies with no miscarriages. It now appears that the gastric adenocarcinoma in the older sibling bears no relationship to the presence of anti-*Tj*⁵ (Walsh and Koopstzoff⁸).

Antitubercular Effect of an Extract of *Adhatoda vasica*

Adhatoda vasica is a small sub-herbaceous bush which grows all over the plains of India and is extensively used in indigenous medicine as a remedy for colds, cough, bronchitis and asthma. Hooper (1888) carried out its chemical analysis and found that it contained an odorous volatile principle and an alkaloid called vasicine. The alkaloid was found to have no action on tubercle bacilli (Chopra *et al.*, 1925).

The antitubercular activity of the volatile principle, which was obtained by steam distillation of the leaves, was determined by the serial dilution method, and the results are shown in the accompanying table.

ANTITUBERCULAR ACTIVITY

Drug	Strain No.	Inoculum	Inhibitory concentration (μgm./c.c.)
Volatile principle	B-10-4 (human)	0.01 mgm./c.c.	2
	B-10-3 (bovine)	"	5
	B-10-1 (avian)	"	5
	B-10-4	"	1
Streptomycin			

The activity of the drug is thus less than half that of streptomycin.

The drug does not produce any toxic symptoms in a dose of 2.3 gm./kgm. when administered to mice orally or subcutaneously.

Various concentrations of the drug were incorporated in the culture of bovine tubercle bacilli in liquid media, and the effect was studied under the electron microscope at various intervals. Under the influence of the drug there is inhibition of growth and the bacilli swell up (Figs. 1 and 2).

(1) Bovine strain of tubercle bacilli four days old. (2) Bacilli after 4 days treatment with active extract of *Adhatoda vasica*. × 10,500. Electron micrographs by Dr. A. Fande and K. Bahadur, National Physical Laboratory, New Delhi.

Preparative Circular Paper Chromatography

FROM the preparative aspect, the conventional paper chromatographic technique is rather limited, in that only a few micrograms of material can be spotted on a single strip or sheet, and the labour involved in the separation of even milligram quantities in this way is enormous. From this point of view the circular paper chromatographic technique¹ offers great possibilities. By a suitable modification of this technique, it has been found possible to obtain from a single chromatogram material of individual components from a mixture of sugars sufficient for the determination of physical constants and preparation of characteristic derivatives.

The essential features of the technique consists in the use of thick and large-size circular filter paper (Whatman No. 3, 35 cm. diam.) and the application of the multiple development technique. The method consists in spotting 0.1–0.2 ml. at a time of the sample containing a mixture of sugars (about 20 per cent each of three to five sugars) at the centre of the paper and drying before another aliquot is superimposed on it until 0.5 ml. of the solution has been applied. The size of the spot can be as large as

Chromatogram showing the separation of large amounts of sugars from a mixture.

(1) Lactose (120 mgm.); (2) maltose (100 mgm.); (3) glucose (100 mgm.); (4) xylose (100 mgm.); (5) rhamnose (50 mgm.). Whatman No. 8 paper; 35 cm. diam. Solvent: *n*-butanol-pyridine-water (80:40:30). Four developments. Reagent: aniline-diphenylamine-phosphoric acid

1.5 in. in diameter. Using *n*-butanol-pyridine-water (80:40:30) as the developing solvent and applying the multiple development technique (four developments) previously described for the resolution of sugars by the circular technique³, clear separation of the sugars can be obtained. The bands relating to the individual sugars can be marked with pencil by cutting small sectors at different regions of the paper and using them as guide sectors after treatment with a chromogenic reagent. The marked-off zones are cut from the paper and the sugars are eluted with water, concentrated and crystallized in the usual manner. In this way 300–500 mgm. of sugars per sheet can be separated and isolated. More than one paper can be developed at a time by spotting the solution on each paper and placing them one above the other clamped between two thick glass plates having a hole at the centre. The development can be carried out by inserting a cylindrical paper wick through the holes, and reaching the solvent in a beaker. By this procedure it is possible to develop four or five chromatograms at a time. In this way large amounts of sugars can be separated. The accompanying photograph shows an example of the application of this technique, which should be of wide application as a preparative method of isolation of sugars and other substances which can be separated by paper chromatography.

A detailed account of this technique will be submitted for publication in the *Journal of the Indian Institute of Science*.

Recovery of Lecithin from the Lecithin - Cadmium Chloride Complex

ALTHOUGH cadmium chloride has been in use at least since 1868 as a precipitant for lecithin, no completely satisfactory method for the removal of cadmium chloride from the complex formed in this manner has been devised. Strecker¹ used hydrogen sulphide to precipitate the cadmium. Bergell², in 1900, made use of ammonium carbonate, and Levene and Simms³, in 1921, introduced the procedure in recent common use, namely, treatment of a chloroform solution of lecithin-cadmium chloride with dry ammonia-methanol solution, both procedures resulting in the precipitation of a cadmium ammonium chloride complex. All these methods, in addition to resulting in poor yields, expose the easily oxidizable and labile lecithin to undesirably harsh treatment, with the result that, however pure the lecithin-cadmium chloride complex may have been, the lecithin finally isolated is once more somewhat impure.

It seemed probable that ion-exchange resins could be used to remove the cadmium chloride from the lecithin complex if a solvent could be found which fulfilled all the following conditions: (a) the complex would be soluble in the solvent, (b) the lecithin would be soluble, (c) the solvent would be sufficiently polar in character to enable the ion-exchange resin to function, and (d) it would not dissolve or in any other way alter the resin. A mixed solvent consisting of ethanol-water-chloroform (7:3:1 by volume) has been found to fulfil these conditions and to function as expected. (It is advantageous first to dissolve the lecithin-cadmium chloride in chloroform and afterwards to add the required amount of 70 per cent ethanol.)

The self-indicating, monobed resin 'Amberlite MB-3' (Resinous Products and Chemical Company) was used. Lecithin-cadmium chloride was prepared from soya bean phospholipids (kindly supplied by Victory Mills, Toronto) by the usual methods and once purified by the method of Pangborn⁴.

A description of two experiments will serve to illustrate the results which have been obtained. 'Amberlite MB-3' was equilibrated, in a flask, with several changes of the mixed solvent, after which a column of resin 10 cm. in height was prepared in an absorption tube 1 cm. in diameter and the solvent drawn off just to the top of the resin column. 500 mgm. of lecithin-cadmium chloride (containing 15.0 mgm. of phosphorus) in 10 ml. of the mixed solvent was introduced above the resin and allowed to flow down by gravity through the column at the rate of 1 ml. in 5 min. The solution was followed by more of the solvent at the same rate until six 5.0-ml. fractions of the effluent had been collected. On analysis these were found to contain 0, 0.65, 6.7, 7.0, 0.65 and 0 mgm. of phosphorus respectively, thus accounting for all the phosphorus. The third effluent fraction contained 3.04 mgm. of nitrogen representing a nitrogen-phosphorus ratio of 1:1.00. Neither cadmium nor chloride was to be found in any of the effluent fractions.

On a slightly larger scale, 2,808 mgm. of lecithin-cadmium chloride in 45 ml. of the mixed solvent was passed at the same rate through a resin column 0.9 cm. x 25 cm. (a 25-ml. burette was used) and followed by 50 ml. of the same solvent at a somewhat faster rate. The effluent was collected in a weighed 300-ml. standard-joint flask and the solvent distilled

¹ Grl, K. V., and Rao, N. A. N., *Nature*, 160, 923 (1953); *J. Ind. Inst. Sci.*, 34, 95 (1953); *Nature*, 171, 1159 (1953).

² Grl, K. V., and Nigam, V. N., *Naturwissenschaften*, 40, 343 (1953); *J. Ind. Inst. Sci.*, 35, 49 (1954).

off *in vacuo* under nitrogen with an all-glass apparatus. (The water-bath temperature was not above 30° C.) Three 10-ml. portions of absolute ethanol were added and each successively distilled off under the same conditions to effect removal of the water. Finally, the contents in the flask were dried to a constant weight in a vacuum desiccator over phosphorus pentoxide and in the presence of nitrogen. The lecithin, a transparent, colourless and amorphous solid, was dissolved in absolute ethanol, quantitatively transferred to a 50-ml. volumetric flask and made to volume. The weight of the lecithin thus prepared was 1,777 mgm. According to Baer and Kates¹, the complex has the structure (lecithin), (cadmium chloride). Assuming a molecular weight of 802 for this lecithin, the yield should have been 1,720 mgm. A lecithin containing one molecule each of stearic and linolenic acids would have a molecular weight of 802 and the following calculated analytical figures: P, 3.86; N, 1.75 per cent; iodine number, 95; analysis gave P, 3.83; N, 1.73; choline-N, 1.73 per cent²; N:P ratio, 1:1.00; iodine number, 86. (It is not to be construed that this is evidence for the presence of stearic or linolenic acids.) The lecithin is optically active, $[\alpha]_D^{25} = 7.0$ (in ethanol). A 10 per cent solution of the lecithin in ethanol has been kept at room temperature for two months without discoloration.

The method described here, when used in conjunction with the excellent procedure of Pangborn for the purification of lecithin—cadmium chloride, makes possible the easy preparation of naturally occurring, unsaturated lecithins with a high degree of purity.

This work was assisted by a grant from the Division of Medical Research, National Research Council of Canada.

Soil Recolonization Tube for studying Recolonization of Sterilized Soil by Micro-organisms

STUDIES of recolonization by fungi and bacteria of soil sterilized, or partially sterilized, by steam or by various fumigants such as formalin, carbon disulphide and chloropicrin have been made by many investigators. A difficulty common to all such investigations has been that of taking samples of the soil in the process of recolonization for plating out and determination of the recolonizing micro-organisms. If the soil has been treated *in situ* in the field, it is necessary to dig profile pits, from the sides of which samples can be taken¹. If the soil has been treated in laboratory containers, it may be necessary to sacrifice one container of soil for each series of samples taken, and this makes it impossible to make consecutive observations on the soil in a

Fig. 1. Soil recolonization tube: hatched, non-sterile inoculum; stippled, sterile soil

single container. Furthermore, the disturbance consequent upon removal of soil before taking a sample much increases the likelihood of contamination of the soil samples by adventitious micro-organisms. To overcome these difficulties, the 'soil recolonization tube', illustrated in Fig. 1, has been designed and found useful in the study of fungal recolonization of sterilized soil. It is proving equally useful for the investigation of soil recolonization by bacteria. By the use of this apparatus, soil samples can be taken with the minimum of labour and of disturbance to the surrounding soil; moreover, successive samples of soil can be taken from a single recolonization tube for an indefinite period, and the succession of recolonizing organisms in space and time can be properly studied.

The recolonization tube consists of an 18-in. length of 'Pyrex' glass tubing, of 1-in. internal diameter, to which six side-arms, 1 in. long and $\frac{1}{4}$ in. internal diameter, are fused at 2-in. intervals. The tube is packed with moist soil, which has previously been passed through a 2-mm. sieve and adjusted to a moisture content of 40 per cent saturation. Trim and even packing is secured by tamping after each addition of 25 gm. of soil. After the tube has been filled, the open ends of the main tube and of the six side-arms are plugged with cotton wool and the whole tube is weighed; soil moisture content can then be maintained at the original level by periodical weighing and restoring to original weight by addition of sterile water through the side-arms (starting at the end farthest from the inoculum of unsterilized soil). If recolonization of steamed or autoclaved soils is to be studied, the tubes can be steamed or autoclaved in the usual way; for treatment of soil with a fumigant such as carbon disulphide or chloropicrin, the cotton-wool plugs are replaced, for the duration of the treatment, by rubber bungs. After the sterilization treatment has been completed and the necessary additional period allowed for evaporation of a volatile fumigant, an inoculum of unsterilized soil is added at one end of the recolonization tube. At suitable intervals of time, small samples of soil are removed through the side-arms of each tube, and from them 'Warcup soil plates' are made for determination of the fungus flora².

Consistent results have been obtained with this technique in successive trials of sterilized and re-inoculated Kettering loam soil. After steam treatment at 1 atm. pressure for 30 min. on two successive days, the first fungal colonists following reinoculation with unsterilized soil were phycomycetous species, such as *Pythium acaeticum* and *Zygomorphus oultonii*. These were regularly followed by *Trichoderma viride*, *Mucor ramannianus* and *Fusarium caeruleum*. If the soil was not packed sufficiently firmly, however, *Trichoderma viride* tended to be the first fungal colonizer.

FORTHCOMING EVENTS

Monday, June 21

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8 p.m.—Annual General Meeting.

LECTURES OF METAL FIRMING (at the Northampton Polytechnic, St. John Street, London, E.C.1), at 6.15 p.m.—Mr. R. L. Samuel and Mr. N. A. Lockington: "Chromium Diffusion as a Commercial Process".

Friday, June 25—Saturday, June 26

BRITISH MYCOLOGICAL SOCIETY (at Cambridge)—Scientific Meeting.

Friday, June 25

At 10.30 a.m. (at the National Institute of Agricultural Botany, Cambridge)—Twenty-eighth Annual Plant Pathology Field Day.

Saturday, June 26

At 9.30 a.m. (in the Large Lecture Room, Botany School, Cambridge)—Scientific Papers on "Infection Phenomena".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

BIOCHEMIST to take part in work on the formation of protein complexes in the dyeing of wool and related problems, with particular reference to soil forming processes—The Secretary, Department of Forestry, Imperial Forestry Institute, University of Oxford (June 23).

DEPUTY CONTROLLER (graduate in physics, chemistry or fuel technology, and experienced in domestic fuel utilization, and the assessment of coke qualities) at the PHYSICAL TESTING LABORATORIES, Bloom Street, Salford, to supervise the examination and testing of all types of gas and coke appliances for domestic use—The Secretary, North Western Gas Board, 60 Whitworth Street, Manchester 1 (June 24).

ASSISTANT, Grade B (with good academic qualifications) in CHEMISTRY—The Clerk to the Governors, Chelsea Polytechnic, Manresa Road, London, S.W.3 (June 25).

RESEARCH ASSISTANT in the DEPARTMENT OF APPLIED MATHEMATICS for theoretical work on upper atmosphere physics—The Professor of Applied Mathematics, Queen's University, Belfast (June 25).

ASSISTANT, Grade B (with a degree or equivalent qualification, and preferably with industrial and/or teaching experience) in the DEPARTMENT OF METALLURGY, County Technical College, Wednesbury—The Director of Education, Department F.B., County Education Office, Stafford (June 26).

ASSISTANT LECTURER (with special qualifications in applied mathematics) in MATHEMATICS—The Registrar, The University, Manchester (June 26).

ASSISTANT LECTURER (with special qualifications in petrology) in GEOLOGY—The Registrar, Trinity College, Dublin (June 26).

EXPERIMENTAL OFFICERS (3) (with a pass degree, H.N.C. or equivalent, in physics), or ASSISTANT EXPERIMENTAL OFFICERS (2) (with G.C.H. in three subjects at advanced level, two of which must be in a science subject), at the NATIONAL PHYSICAL LABORATORY, Teddington, Middlesex, for work on (a) precision temperature and pressure measurements and (b) radiology—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.149/54A (June 26).

LECTURER (honours graduate, with a knowledge of advanced physical metallurgy and an interest in X-ray metallography) in the DEPARTMENT OF METALLURGY—The Registrar, The University, Liverpool (June 26).

LECTURER (preferably with special qualifications in palaeontology and stratigraphy) in GEOLOGY—The Registrar, King's College (University of Durham), Newcastle-upon-Tyne (June 26).

SCIENTIST, Grade II or III (with a first- or good second-class honours degree in physics, engineering, biology, mathematics or statistics, and experience in field, laboratory or operational research, and preferably with experience in the writing of research reports) in the FIELD INVESTIGATION GROUP, to carry out field work as collector, and some will take charge of small teams—The National Coal Board Establishments (Personnel), Hobart House, London, S.W.1, quoting TT/781 (June 26).

ASSISTANT AGRICULTURAL ECONOMIST (with a degree in economics or agriculture with economics) in the DEPARTMENT OF AGRICULTURAL ECONOMICS—The Registrar, The University, Manchester (June 26).

LECTURER in PHYSIOLOGY—The Secretary of University Court, The University, Glasgow (June 26).

PRINCIPAL SCIENTIFIC OFFICER (preferably with some previous experience in the physiology of the nervous system and of the special senses, and a first- or second-class honours degree in an appropriate subject) at the R.A.F. Institute of Aviation Medicine, Centrifuge Unit, South Farnborough, Hants, to take charge of small scientific unit concerned with the effects of acceleration on man and animals, and to be responsible for detailed planning, from a fundamental aspect, of a long-term programme of a physiological nature dealing largely with changes in the circulation—The Civil Service Commission, Scientific Branch, 90 Old Burlington Street, London, W.1, quoting S.4339/54 (June 26).

RESEARCH SCIENTISTS (with a good university degree or equivalent in physics, physical chemistry or electrical engineering) for work on coal preparation, also laboratory and pilot scale investigation into novel methods of separating coal from associated minerals—The National Coal Board Central Research Establishment, Stoke Orchard, near Cheltenham, Glos. quoting TT/783 (June 26).

UNIVERSITY DEMONSTRATOR (preferably with qualifications in stratigraphy) in the DEPARTMENT OF GEOLOGY, University of Cambridge—Mr. W. B. Harland, Secretary of the Appointments Committee of the Faculty of Geography and Geology, Sedgwick Museum of Geology, Downing Street, Cambridge (June 25).

ANALYTICAL CHEMIST in the DEPARTMENT OF AGRICULTURAL CHEMISTRY—The Registrar, Wye College, near Ashford, Kent (June 30).

LECTURER in BIOCHEMISTRY at University College, Dundee—The Secretary, University of St. Andrews, College Gate, St. Andrews (June 30).

LECTURER in ECONOMIC STATISTICS at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, June 30).

LECTURER in HISTOLOGY within the Department of Anatomy—The Medical Secretary, Middlesex Hospital Medical School, London, W.1 (June 30).

LECTURER (with special interests in fluid mechanics) in ENGINEERING—The Registrar, King's College, Strand, London, W.C.2 (June 30).

LECTURERS, Grade I, in AGRICULTURE, and an ASSISTANT LECTURER in ANIMAL HUSBANDRY, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (June 30).

PHYSICIST, basic grade (with a first- or second-class honours degree in physics, whose main interests lie either in classical physics or in atomic physics), in the REGIONAL PHYSICS DEPARTMENT—The Administrative Officer, Board of Management for Glasgow Western Hospitals, Regional Physics Department (Western Regional Hospital Board), 9-11 West Graham Street, Glasgow, G.4 (June 30).

PROFESSOR OF AGRICULTURE—The Registrar, The University, Reading (June 30).

LECTURER in CHEMICAL PATHOLOGY at the University College of the West Indies—The Secretary, Senate Committee on Higher Education in the Colonies, University of London, Senate House, London, W.C.1 (July 1).

LECTURER in PSYCHOLOGY—The Secretary, London School of Economics and Political Science, Houghton Street, Aldwych, London, W.C.2 (July 1).

RESEARCH ASSISTANT (with a degree in chemistry) in the DEPARTMENT OF CHEMISTRY AND BIOLOGY—The Secretary, Norwood Technical College, Knight's Hill, West Norwood, London, S.W.17 (July 1).

LECTURER in BIOPHYSICS in the DEPARTMENT OF PHYSIOLOGY—The Secretary, The University, Edinburgh (July 3).

SENIOR LECTURER, and a LECTURER, Grade I, in CHEMISTRY, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (July 3).

ASSISTANT LECTURER in PHYSICS—The Registrar, University College of North Staffordshire, Keele, Staffs (July 10).

CHAIR OF CHEMISTRY in Makerere College, University College of East Africa—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (July 10).

LECTURER and an ASSISTANT LECTURER in the DEPARTMENT OF GEOGRAPHY—The Registrar, The University, Manchester 13 (July 10).

LECTURER in INORGANIC AND PHYSICAL CHEMISTRY—The Secretary, The University, Edinburgh (July 15).

ASSISTANTS (2) in the DEPARTMENT OF ZOOLOGY—The Secretary, The University, Edinburgh (July 17).

CHAIR OF ANATOMY at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Hong Kong, July 31).

PROFESSOR OF MICROBIOLOGY at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 31).

SENIOR LECTURER in CIVIL ENGINEERING at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Hong Kong, July 31).

ASSISTANT, Grade B (with graduate or A.B.I.C. qualifications) in CHEMISTRY—The Principal, Technical College, Queen Street South, Huddersfield.

BACTERIOLOGICAL TECHNICIAN to assist in an investigation of bacterial viruses, and to be fully responsible for the preparation of media—The Secretary, Royal Cancer Hospital, Fulham Road, London, S.W.3.

BIOLOGIST (Assistant Experimental Officer or Experimental Officer grade), to work on plankton in the Edinburgh Laboratory of the Scottish Marine Biological Association—The Officer in Charge, Oceanographic Laboratory, 78 Orleigh Road, Edinburgh 5.

ELECTRONIC ENGINEERS and PHYSICIANS (Scientific Officer, Assistant Experimental Officer and Experimental Officer grades), at Ministry of Supply Experimental Establishments at Farnborough, Hants, Malvern, Wotton, and Sevenoaks, Kent, and elsewhere, mainly in Southern England, for duties which include research, development or design of telecommunications and radar equipment; guidance and control systems; and instrumentation for a variety of research problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.206/54A.

INDEXER (female) (preferably with a degree or equivalent), to assist in preparing indexes, answering inquiries and proof reading—The Director, Commonwealth Bureau of Dairy Science, Shinfield, Reading, Berks.

MATHEMATICIANS (Scientific Officer, Assistant Experimental Officer and Experimental Officer grades), at Ministry of Supply Research and Development Establishments mainly in Southern England, for work on a wide range of problems chiefly concerned with aircraft, radio and radar equipment and armaments—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.141/54A.

MINERALOGIST CHEMIST (with first- or good second-class honours degree in geology or chemistry, and experience in the analysis, identification, study, etc., of mineral species), with H.M. Colonial Service in Tanganyika—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD 106/8/04.

PHYSICIST or MECHANICAL ENGINEER to undertake fundamental and applied research on certain mechanical processes employed in textile finishing; a **PHYSICIST or TEXTILE TECHNOLOGIST** for fundamental and technical researches in the process of doubling, which consists essentially of the twisting together of yarns; and a **PHYSICIST or RESEARCH ENGINEER** (preferably with a knowledge of experimental stress analysis) for research on weaving machinery.—The Director, British Cotton Industry Research Association, Solihull Institute, Didsbury, Manchester 20.

PHYSICIST (with a degree in physics and capable of applying experimental techniques to the solution of fluid problems in the iron and steel industry) in the **FLUID DYNAMICS SECTION** of the Physics Department, British Iron and Steel Research Association, London—The Personnel Officer, B.I.S.R.A., 11 Park Lane, London, W.1.

RESEARCH ASSISTANT in the field of PHYSICAL CHEMISTRY—The Secretary, University College, Exeter.

RESEARCH ASSISTANT (science graduate (physiology or biochemistry)), in the **BLOOD PRODUCTS LABORATORY**—The Secretary, Lister Institute, Herts, Herts.

SCIENTIFIC OFFICER, Grade 8 (with a university degree of high standard in aeronautical engineering or equivalent qualifications, and several years experience in wind tunnel investigations related to the aerodynamic development of aircraft and missiles), in the **AERONAUTICAL RESEARCH LABORATORIES**, Fishermen's Bend, Victoria, Australia, to work on the aerodynamic development and research relating to new types of aircraft and missiles, and to general problems in low speed aerodynamics—The Senior Representative (A.P.17), Department of Supply, Australia House, London, W.O.2, quoting "Position No. 239".

SENIOR LABORATORY TECHNICIAN (with experience in a physics laboratory of an educational institution) in the **PHYSICS LABORATORY**—The Secretary, Borough Polytechnic, Borough Road, London, S.E.1.

SENIOR LABORATORY (with at least three years teaching experience at a British university) in (a) **CIVIL ENGINEERING** (including surveying), (b) **ELECTRICAL ENGINEERING** (electro power), and (c) **Mechanical Engineering** (heat engines and refrigeration), at the Engineering College, Rangoon University—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.12/B.M. (a), (b), (c)/54.

The Policy for Education

provides a means of saving for a child's education.
For example, - for a parent aged 35 next birthday,

The Society pays

£100 p.a. for 5 years, beginning in 15 years' time,
and

if the parent dies within 15 years, £100 p.a. in the
meantime towards the child's maintenance.

The cost is

£8 7s 6d a quarter for 15 years at most.

Enquire for details, giving the ages of parent and child.

The Equitable Life Assurance Society

LECTURES AND COURSES

BRADFORD EDUCATION
COMMITTEETECHNICAL COLLEGE, BRADFORD
CHEMICAL ENGINEERING

Courses in preparation for the degree of B.Sc. (Chemical Engineering) in chemical engineering, the A.M.I.Chem.E., and the higher national certificate are arranged.

Further particulars may be obtained from the Principal, Technical College, Bradford, 7.

OFFICIAL APPOINTMENTS

The appointment of persons answering these advertisements must be made through a Local Office of the Ministry of Labour or a Scheduled Employment Agency if the applicant is a man aged 18 to 64 inclusive, or a woman aged 18 to 59 inclusive, unless he or she, or the employment, is exempted from the provisions of the Notification of Vacancies Order, 1952.

H.M. COLONIAL SERVICE

Applications are invited for the following post Tobacco Research Officer, Department of Agriculture, Nyasaland, to carry out experimental work on tobacco growing and curing under the general direction of a tobacco expert. Candidates must be male, and should possess a good honours degree in botany, agricultural botany or agriculture, and have had at least two years' postgraduate training and experience in field experimentation and crop husbandry generally. Appointment on probation in the Colonial Research Service in either the Scientific Officer scale (£400 to £650 per annum, plus an overseas research allowance of £100 to £140 per annum) or the Senior Scientific Officer scale (£750 to £950 per annum, plus an overseas research allowance of £135 to £220 per annum), according to age and experience. Local cost-of-living allowance, at present at the rate of 20 per cent of first £500 of salary and 10 per cent of remainder (maximum £200 per annum) also payable. Outfit allowance £60 on first appointment. Contributory superannuation scheme. Income tax at local rates. Free passages on appointment and leave for officer, wife and children under 13 years of age. Government quarters, when available, at a rental of up to 10 per cent of basic salary (maximum £150 per annum).

Apply in writing to the Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, giving briefly age, qualifications and experience. Mention the reference number CDE 63/4/04.

H.M. COLONIAL SERVICE

Applications are invited for the following post Chemist, Agricultural Department, Sierra Leone, to make soil survey of part of the Northern Province of Sierra Leone, with particular reference to the nutrient status and fertilizer requirements of soils suitable for mechanized rice cultivation. Candidates must hold a degree in natural science, and preferably have had post-graduate experience, particularly in soil survey work. Appointment on contract for a tour of eighteen to twenty-four months in the first instance in the salary scale £616 to £1,408 per annum, plus an expatriation allowance of £182 to £250 per annum. A gratuity of £25 to £37 10s for each completed three-month period of satisfactory service is payable on termination of contract. Outfit allowance of £60 on first appointment. Free passages for officer, wife and up to two children under the age of 10. Government quarters, when available, at a rental of up to 10 per cent of salary (maximum £150 per annum).

Apply in writing to the Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, giving briefly age, qualifications and experience. Mention the reference number CDE 63/15/04.

SURREY EDUCATION
COMMITTEEGUILDFORD COUNTY TECHNICAL
COLLEGE

STOKE PARK, GUILDFORD

Applications are invited for the post of Assistant, Grade B, to teach physics and mathematics in the G.C.E. and national certificate courses. Candidates should be graduates in physics, with some teaching and preferably industrial experience.

Application forms and further particulars may be obtained from the Principal on receipt of stamped, addressed envelope. Last date for applications, June 26, 1954.

SOUTH PACIFIC COMMISSION
PHYSICIAN-NUTRITIONIST

Applications are invited for the post of Physician-Nutritionist with the South Pacific Commission. The Physician-Nutritionist will be stationed in Noumea, New Caledonia, and will be required to assist and stimulate the assessment and improvement of the dietary patterns and nutritional status of the South Pacific peoples. To this end he will have to direct, co-ordinate and supervise the work of a dietitian-nutritionist, a biochemist and a food technologist, and to co-operate with other Commission officers working on related aspects (agriculture, fisheries, etc.). Applicants must be fully qualified medical practitioners from a recognized faculty of medicine, must have completed postgraduate training in nutrition and must have had some field experience in nutrition work under tropical conditions. Fluency in English and French is very desirable. The appointment will be for three years. The commencing salary will be between £1,750 and £2,000 sterling, according to qualifications and experience, with annual increments and substantial allowances. No local income tax is payable.

Applications, supported by a detailed curriculum vitae, should be sent to the Secretary-General, South Pacific Commission, Noumea, New Caledonia.

INSTITUTE OF CANCER
RESEARCHROYAL CANCER HOSPITAL,
FULHAM ROAD, S.W.3

A Chemist is required for a new radio-isotopes laboratory under construction at Pollards Wood Research Station, Chalfont St Giles, Bucks, to take part in the investigation of biochemical processes such as the incorporation of amino-acids in animal tissues and the action on the cell of cytotoxic and other chemical agents, by the use of radioactive tracer techniques. Salary will be according to age, qualifications and experience. The post is permanent and superannuable, with family allowances.

Applications, giving the names of two referees, should be addressed to reach the Secretary, not later than July 3, 1954.

UNIVERSITY COLLEGE OF
WALES

ABERYNRYWYTH

Applications are invited from persons with veterinary qualifications for the post of Lecturer in Animal Physiology and Animal Health in the Department of Agriculture (Animal Husbandry). Salary according to experience and qualifications within the scale £550 to £1,100 (with an efficiency bar at £800).

Applications should be sent to the Registrar, from whom further particulars can be obtained, by June 30, 1954.

MINISTRY OF SUPPLY HAS VACANCIES in Experimental Establishments in or near London involving computational work connected with performance of armaments and aircraft. Supervision of small group of assistants and some responsibility for development of new computing techniques and for interpretation of results. Qualifications: higher school certificate (science) or equivalent; pass degree in mathematics or experience of computing, aerodynamics, statistics, etc. an advantage. Appointments graded according to age and experience as Experimental Officer (minimum age 26) £720 to £890 (London), £690 to £850 (provinces); Assistant Experimental Officer £290 (age 18) to £645 (London), £276 to £615 (provinces). Women somewhat less. Appointments unestablished.—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (IO), 26 King Street, London, S.W.1, quoting A.154/54A. Closing date July 3, 1954.

MEDICAL TECHNICIAN REQUIRED BY Ministry of Supply for Research Establishment near Salisbury, Wilt., to take charge of small clinical laboratory for haematology and general clinical observations. Minimum qualification higher school certificate or equivalent, but additionally membership of the Institute of Medical Technology desirable. Alternatively Fellowship of I.M.L.T. or Associateship, plus a period of appropriate experience. Post is graded as Assistant Experimental Officer. Salary within range £276 (age 18) to £615. Women somewhat less. This appointment is unestablished, but pensionable post exists for candidate within prescribed age limits and who is otherwise suitably qualified.—Application forms from Ministry of Labour and National Service, Technical and Scientific Register (IO), 26 King Street, London, S.W.1, quoting G.188/54A. Closing date July 3, 1954.

H.M. COLONIAL SERVICE

Applications are invited for the following post Livestock Research Officer, Eboli Livestock Experimental Station, British Guiana. Duties include the planning and supervision of research and other projects for the purpose of ascertaining the most economic methods of developing commercially-deficient savannahs of the area. Candidates should possess a good honours degree in agriculture, or the equivalent, with at least five years' postgraduate experience in field experimentation and tropical agriculture, with particular reference to pasture management at animal husbandry. Eboli is an isolated station situated about 75 miles up the Berbice River and offering virtually no opportunities for organized social life, but the living conditions are not unpleasant, and visits can be made to Headquarters at frequent intervals. Appointment on probation in the Colonial Research Service in the Principal Scientific Officer scale (£1,000 to £1,375 p.a.), plus an overseas research allowance of £250 to £170 per annum. Outfit allowance £60. Unfurnished quarters provided at a rental of 8 per cent of salary up to a maximum of £12k per annum. Free passages on appointment and on leave for officer, wife and children under 13 years of age.

Apply in writing to the Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, giving briefly age, qualifications and experience. Mention the reference number BCD.87/30/01.

UNIVERSITY COLLEGE OF SOUTH
WALES AND MONMOUTHSHIRE
CATHAYS PARK, CARDIFF

Applications are invited for the post of Lecturer in Engineering. Commencing salary according to qualifications and experience in the range £550 to £800, in the salary scale £550 to £50 to £1,100 per annum. Preference will be given to applicants specializing in teaching mechanical engineering.

Eight copies of applications (including the names of three referees) should be sent no later than July 3, 1954, to the undersigned, from whom further particulars may be obtained.

R. R. EVANS,
Registrar.

UNIVERSITY OF MELBOURNE
AUSTRALIA

Applications are invited for a position of Senior Lecturer in Geology. Duties include teaching under the general direction of the Head of Department, Professor R. S. Hills, F.R.S. especially in economic geology and geochemistry. Preference will be given to applicants qualified and willing to develop research in geochemistry. The salary will be £A.1,500 to £A.1,750 p.a. annum, according to qualifications. Superannuation is similar to F.S.S.U.

Further particulars and information as to method of application may be obtained from the Secretary, Association of Universities of British Commonwealth, 5 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in Australia and London, July 19, 1954.

LONDON COUNTY COUNCIL

PART-TIME POST

ELTHAM HILL SCHOOL, ELTHAM HILL
S.E.9

Applications invited for part-time work (three days a week), to teach general science, mathematics and chemistry in middle school, from September, in this grammar school for 500 girls 11 to 18. Temporary appointment; proportionate annual salary, Burnham (London) Scale.

Apply at once to Headmistress of school, or Form 80/T840, obtainable from Education Officer (80/T82), County Hall, S.E.1 (708).

TECHNICAL LIBRARIAN AND INFORMATION Officer required to establish and develop information department and library in an important industrial organization in the Midlands. Candidates must be Chartered Librarians with considerable experience in industrial libraries, technical or scientific qualification would be an advantage. Starting salary, £600 to £700, according to qualifications and experience.—Applications, giving details of experience, age and present salary, to the Director, Adult, 4 Palace Gate, London, W.8.

TECHNICIAN (BIOCHEMICAL) REQUIRED for research and some routine work on steroid. Experience in organic chemistry desirable. Salary scale £470 to £545.—Applications, stating age, sex, qualifications, details of experience, and names of two referees, to Secretary, St. Mary Hospital Medical School, Paddington, W.2.

SHANDON CHROMATOGRAPHY DRYING OVEN

Specially designed for chromatography and paper electrophoresis, Shandon's latest equipment offers:

- ★ Drying of papers at uniform temperatures, a feature which is indispensable for consistently accurate, reproducible, and comparable chromatograms.
- ★ Simultaneous drying of 12 large sheets up to 24 in. × 24 in., hung on pull-out rack giving free access to all papers.
- ★ Heating of all papers under strictly identical conditions through continuous horizontal forced air circulation by centrifugal fan.
- ★ Accurately controlled heating from ambient temperature to 110° C. by manual or fully automatic regulation.
- ★ Solvent vapours continually exhausted through adjustable outlet. (The oven can also be run as a closed system.)
- ★ Shelves are available for immediate conversion into general purpose laboratory oven.

MSE Homogeniser

The most versatile laboratory mixer made. It takes three different types and sizes of container enabling it to handle quantities from 100 c.c. down to 3 c.c. Speed is infinitely variable up to 14,000 r.p.m. The housing for the 100 c.c. and 10 c.c. containers can be filled with dry ice or other convenient coolant, providing effective counter-action to the temperature rise normally met in high-speed blending.

SCIENTIFIC RESEARCH AND EXPOSITION

EFFECTIVE exposition of a scientific theme is highly important at the present day, and two recently published books* provide good examples of it. Herr Jungk's book has the narrower scope, in that he limits his survey to the American scene and describes some of the projects and achievements of American scientists in the exploration of space, the development of atomic energy, in agriculture and horticulture, the control of weather, in animal biology, industrial psychology, the electronic computer and the like. By and large, he is concerned rather to depict the actual impact of such projects and achievements on the social order, and to suggest their probable effect on the society of to-morrow. In particular, he gives a graphic picture of the changes which the atomic energy programme has already wrought in Colorado, at Los Alamos, in Nevada and elsewhere. His book is a series of snapshots of a world in which man has already changed his environment and himself, rather than of the discoveries by which man has gained such control over Nature.

Mr. Kaempffert (see also p. 1211) touches on the exploration of space, the ionosphere, weather control, supersonic flight, atomic energy, the possibilities of generating energy from the sun, advances in animal and human biology and their implication for the control or prevention of diseases like cancer, but he gives a highly skilled and readily intelligible exposition of the scientific discoveries concerned, the way they have been made and something of what they mean for mankind. Further, Mr. Kaempffert's book is not restricted to the American scene. Moreover, its clear pictures of the nature of the process of scientific discovery and the working of the scientific mind depict the scientist as a human being, whereas Herr Jungk's picture of the scientist is that of a mystery man, even one who is carrying the conquest of Nature so far as to attempt to make himself into a god. In an address to the American Association for the Advancement of Science at Philadelphia in December 1951, Prof. Kirtley Mather discussed such anti-scientific tendencies and their significance. While such trends have undoubtedly caused scientists themselves to consider more carefully the social consequences of their work, it has not been made any easier thereby for science to make its full contribution to human welfare and the practical affairs of everyday life. Indeed, as much of the discussion over the hydrogen bomb indicates, muddled thinking and a confusion of moral issues with practical affairs lead to evasion of the hard intellectual effort required to evolve adequate means of international control and co-operation, which are the real challenge of the situation.

* Tomorrow is Already Here: Scenes from a Man-Made World. By Robert Jungk. (Translated from the German by Marguerite Waldman.) Pp. 220+15 plates. (London: Rupert Hart-Davis, Ltd., 1954.) 16s. net.

Explorations in Science. By Waldemar Kaempffert. Pp. 288. (London: Victor Gollancz, Ltd., 1953.) 12s. 6d. net.

Both books, it is true, demonstrate the inescapable contact between science and politics; but whereas Herr Jungk gives no indication as to how that contact should be guided, Mr. Kaempffert shows that there is a certain amount of common ground, and that it is possible for the scientist and politician to walk together on terms of mutual respect and understanding. That is to say, Mr. Kaempffert has not stopped at exposition: he has carried his venture in communication to the point of interpretation, so that the ordinary citizen, whether politician or scientist working at some other frontier of knowledge, farmer, salesman, housewife, airman or soldier, can gain some understanding of what the scientist is doing, how he goes about his work, its implications for the world of to-day and the conditions essential for the continuance of such scientific work. In the main, this is done in the concluding three chapters of the book, in which Mr. Kaempffert explains the nature of the scientific method and its requirements, and how it is that the application of scientific discovery inevitably involves social change, paying at the same time a deserved tribute to Wells's efforts in this direction. Nevertheless, the same theme is implicit and often explicit in his accounts of particular developments in the earlier part of the book.

This interdependence of science and politics was brought out even more effectively by Prof. Kirtley Mather in his retiring presidential address to the American Association for the Advancement of Science in December 1952. That interdependence, he urged, especially the increasing dependence of fundamental science upon public funds, has made it imperative to make the common ground of science and politics more obvious, to encourage the co-operation of scientists and politicians in the service of mankind, and to eliminate recrimination and distrust. Prof. Mather referred then to the marked reluctance of scientists in the United States to enter Federal Government service, and foretold the further damage to relations between scientists and the Federal Government done by the passage of the McCarran Act by Congress over the President's veto.

On this point of the conflict between intellectual freedom, essential to scientific progress, and national security, and the contribution of the individual or minority to creative thought, Prof. Mather expounded the real issues no less vividly than Prof. A. Macbeath did in his 'plea for heretics' before the British Association at Belfast. Nor did he hesitate to insist that the ideas of competent scientists should play an effective part in determining the limits of security measures. He recognized that the removal of the present stultifying atmosphere and the acceptance of reasonable standards for scientific freedom demand a public understanding which can only come with education and the establishment of effective means of communication—interpretation as well as exposition.

That is a task of integration in which both scientists and politicians have a place. The scientist must assist in developing a climate of opinion that recognizes the supreme worth of intellectual freedom. He must resist vigorously any tendencies in education or

elsewhere that pervert democratic institutions into means for the expression of group prejudice and autocracy inimical alike to science and the general well-being.

Referring again to the books by Dr. Jungk and Mr. Kaempffert, it must be pointed out that both authors bring out very clearly the conditions of scientific advance and the grave danger to science in the United States and elsewhere arising from the real or imagined need for secrecy and its effect on the free exchange of information and ideas. Both Jungk and Kaempffert put this issue of freedom of communication, debate and discussion in its proper perspective in relation to scientific advance; and the consequences of failing to hold a reasonable balance in practice between the claims of 'security' and the exploration upon which real continuing security depends are clearly shown.

But this is only one illustration of the importance of clear interpretation of the possibilities in presenting science to the public. Interpretation is one of the most important functions in the presentation of science and the scientist has the duty at least to assist in that interpretation. But it may not succeed until the non-scientist realizes that science is not necessarily linked up with atom bombs and destruction. Neglect to carry out that task may well involve restraints on scientific work which may gravely hinder its prosecution. It may result in disastrous direction from outside or the withholding of essential funds, now increasingly drawn from public sources.

Scientific advance itself, no less than the effective application of science in industrial and national affairs, depends increasingly on the extent to which not merely the government, but also the ordinary citizens on whose support government ultimately depends in a democracy, should have some understanding of what is happening in science, an appreciation of how it can be wisely utilized and a sense of responsibility for its prosecution. That is one of the primary reasons for the concern of the scientist with the problem of education as a whole; the effectiveness of the educational system determines largely the means he must adopt to deal with his problem of communication as well as the efficiency of those means. Also, as corollary, it requires him to examine closely his objectives in this task of communication and the appropriateness of the means at his disposal.

The importance of this latter factor was well illustrated by the Reith Lectures given last year by Prof. J. R. Oppenheimer. The Reith Lectures are above all an attempt to communicate not so much information as ideas to a widespread serious and attentive audience. Their success in achieving their declared purpose is to be judged by the extent to which they stimulate thought and promote public understanding of some great issues of the day, or in other words, just that understanding and sense of responsibility upon which we have frequently insisted in respect of science.

Nevertheless, the criteria of success are not mass criteria. It is true that the Reith lecturer, like other expositors and interpreters, requires

some understanding of the outlook, the sympathies and the limitations of the ordinary folk who make up the millions of his listeners; he is equally entitled to expect of his listeners a more serious intellectual effort than would be expected of the viewer at a cinema or the ordinary television programme. Exposition and interpretation are more than entertainment. They involve co-operation, but that co-operation will only be secured if interest is aroused. The comparative failure of Prof. Oppenheimer's lectures to make any effective impact on so many of his listeners was, however, not due so much to the scientific limitations of his audience as to failure to present his theme in a setting which, by challenging and capturing the interest of his listeners, would induce them to make just the necessary effort for them to apprehend, even without a scientific or mathematical training, something of the bearing of scientific thought, and nuclear physics in particular, on the society of to-day. That it can be done Oppenheimer himself has shown, for example, in an earlier article on the encouragement of science, in which he expounded a letter of Jefferson on the relations between science and political life in a way that no hearer of the Reith Lectures could have failed to apprehend. Nor need erudition exclude either creative thought or the stimulation of healthy argument.

The Reith Lectures are not, of course, limited to the presentation of a scientific world picture, and it has to be admitted that those given by scientists have not been among the most successful. An even more serious defect, however, in another series has been the failure of the lecturer to take account of the limitations of such a vast audience, so that the picture of world history which he presented became dangerously tendentious where members of his audience did not possess the knowledge to correct the effect of deliberate or accidental omissions. None the less, such lecturers as Lord Russell, Mr. Robert Birley and Lord Radcliffe have achieved such success in stimulating thought and presenting vital issues that the possibilities of this method of communication should be fully explored and utilized, and there is every reason for believing that Sir Oliver Frank's forthcoming lectures on "Britain and the Tide of World Affairs" will touch as high a level as any of the earlier lectures.

At a time when, however, the educational and formative influence of such a new mass media as television is still a matter of discussion and experiment, and when the scarcity of science teachers in the schools threatens both the supply of scientists and the education in science of the general citizen, and especially of the leaders in all walks of life, it is well to remember that the effectiveness of the exposition of science is not set solely by the skilfulness of the expositor in presentation or interpretation. His choice of means is limited in part by the general level of education and understanding of the community in general. These are the factors which determine the amount of co-operation on which he can depend in arousing and maintaining interest. When all stress has been laid on the need for scientists

as such to address themselves much more carefully to this question of communication and presentation, to co-operate fully with those who take up this task, whether they be scientists themselves or journalists, and whether the media be the spoken, the written, or the broadcast word, or the newer visual media, it still remains true that it is in the schools that the foundations of the understanding of science must be laid. Unless the beginning made there is sound, no efforts of scientists or others in the presentation of science are likely to convey to the ordinary citizen the real understanding which he needs, of what science is, and how it can contribute to the welfare of man or, if misused, to the undoing of mankind.

THE DISPLACED SCHOLARS AND SCIENTISTS OF 1933-52

The Rescue and Achievement of Refugee Scholars
The Story of Displaced Scholars and Scientists 1933-1952. By Norman Bentwich. (Studies in Social Life—1.) Pp. xiv+108. (The Hague: Martinus Nijhoff, N.V., 1953.) 6.25 guilders.

THE story which Prof. Norman Bentwich has to tell of the refugee scholars who were displaced from the Dictator-States between the years 1933 and 1952 is brim-full of human interest. When in the former year Hitler came into power as Chancellor of the German Reich, he took advantage of the unfortunate circumstance that the universities and research institutes were in general State-owned and their staffs State officials, so that it was an easy matter to 'cleanse' such establishments by ordering that all those considered to be of other than 'Aryan' origin, or not whole-hearted Nazis, should be summarily dismissed. This led to the elimination of more than twelve hundred scholars and scientists within the next two years. Inside Germany itself, there was but little resistance to this drastic policy, and the few who objected were themselves removed. Nor was there within Germany itself any organized movement to help those thrown out; any help that did come had to be from outside.

It is in this way that the author introduces his subject, and all that happened in those critical years had a deep influence on what was to follow when the countries of eastern Europe came more and more under German control. That the institutions concerned were attached so intimately to the State would, no doubt, not have been so serious a handicap in the days when there existed many small dukedoms and principalities to which a rejected scholar could turn; but it became devastating when an all-embracing central government was in such complete control that even rectorial heads had to model themselves to behave as little 'Führers'. In fact, as was graphically said in an article in the *Universities Review* of April 1936, by Prof. A. V. Hill, Sir F. Gowland Hopkins and Sir Frederic Kenyon: "A German university under the new regime is as to the one part a regiment preparing for war, as to the other an intellectual concentration camp".

Efforts directed towards the rescue of scholarship were made in increasing degree by Western States, largely on the initiative of Great Britain, which set up, under the presidency of Lord Rutherford, an

Academic Assistance Council (succeeded a few years later by the larger "Society for the Protection of Science and Learning", which is still functioning). In 1935 the U.S.S.R. itself became one of the many States in which displaced scholars could find temporary shelter; but that did not long endure, and by 1936 there followed the forced return of almost all of them and even the imprisonment of some. By this time the number displaced from the German universities had risen to seventeen hundred, and their conditions of life became steadily worse. (Although China in its turn became another source of academic exiles, this chiefly concerned the student body and is therefore not included in Prof. Bentwich's survey; it was looked after by the International Student Service with a centre in Geneva.)

The Nazi attack on scholars in Austria and Italy in 1938 led to the displacement of a further five hundred university teachers and scholars. Here again, willing help was given by Britain to the victims; but with the outbreak of the Second World War it was realized that private aid could not carry so heavy a burden by itself and that the British Government must needs shoulder a large portion of it. As the war area spread, other Western European countries suffered in much the same way, and if the means of escape became harder the ingenuity employed became greater: the famous scientist, Niels Bohr, had to get away in a fishing boat at night.

By 1945 the total number of academic refugees registered by the Society for the Protection of Science and Learning rose to more than twenty-five hundred; of those, about half were from Germany and the rest from other European countries. In Britain and the United States the number each received was more than six hundred, most of whom have since become part of the scholarly groups in those two countries.

When Hitler began this cruel and foolish attack on German scientists, he is reported to have said: "If the dismissal of Jewish scientists means the annihilation of contemporary German science, we shall do without science for a few years". Seven years later Sir Winston Churchill thus assessed the fatal consequence: "Since the Germans drove the Jews out of Germany . . . our science is definitely ahead of theirs"; this is graphically epitomized by Prof. Bentwich as "the Nemesis which attended the National Hubris of the Nazis".

In an eloquent epilogue, Prof. A. V. Hill sums up the story of those hard days: the Academic Assistance Council, he says, had no partisan, political or national bias, and indiscriminate relief was no part of its work. "Its purpose was to act as a link between the scientific workers and other scholars displaced and the universities and research institutions of the world, so that their exceptional abilities exceptionally trained—to quote the noble declaration of the Council's founders—should not be lost". Those who took part in it may well be moved with pride—and humility—when reminded by some friend of the many perils in which scholarship then stood and how the danger had been alleviated by the sympathy and generosity of fellow workers in the West.

Prof. Bentwich aims also at the inclusion of some account of the subsequent achievements of the refugee scholars; but it may be questioned whether this is really necessary. The qualities of the men and the response they naturally made to the opportunities of work opened so gladly to them tell unaided their own story.

H. E. WIMPERIS

MALAYAN ORCHIDS

A Revised Flora of Malaya

An Illustrated Systematic Account of the Malayan Flora, Including Commonly Cultivated Plants. Vol. 1: Orchids of Malaya. By Prof. R. E. Holttum. Pp. v+753+4 plates. (Singapore: Government Printing Office, 1953.) 20 Malayan dollars.

THE continuous advance in our knowledge of the floras of the world renders necessary the appearance at intervals of summations of that knowledge, either in the form of monographic studies of natural groups of plants, or of Floras of various geographical regions. One region in which a new presentation of our knowledge is required is Malaya, since Ridley's "Flora of the Malay Peninsula" was published about thirty years ago and, moreover, was to a considerable extent based on insufficient data.

The appearance of the first volume of a new Flora of this region is therefore to be welcomed, and it is a happy choice that this volume should deal with the Orchidaceae, a family of outstanding interest both to the scientific botanist and to the plant lover. Prof. R. E. Holttum has long been interested in these plants; but it was only during the war-time occupation of Singapore by the Japanese that he perforce had the leisure in which to carry out the work necessary for the preparation of the present book.

Apart from botanical exploration in Malaya itself since the publication of Ridley's Flora and the incorporation of the results into a new Flora, it has been essential to consider the Malayan orchids in the light of the extensive researches carried out by the late Dr. J. J. Smith on the orchids of the Malaysian region in general. Smith's work is of fundamental importance in the study of the orchids of this region, and the application of the results of his researches to the Malayan orchids has necessitated many changes from the names and classification in Ridley's account.

Most Floras include, in addition to the native species, a selection of the more important established aliens, but Prof. Holttum breaks new ground by including accounts of the genera, species and hybrids more generally cultivated in Malaya. This renders the book of interest to orchid growers as well and permits of a wider treatment of genera and sub-generic groups. This is advantageous when the cultivated plants are of Malaysian origin, since the native orchids of Malaya are a rather scrappy selection of the total Indo-Malaysian orchid flora. The inclusion of American and African groups and genera is less satisfactory. It is impossible in the space available to deal with these groups adequately, though it must be confessed that the author has provided much useful information. The writer is somewhat sceptical, however, of the possibility of naming with certainty many of these exotic orchids from the data provided; moreover, the introduction of new species and the continuous production of new hybrids will fairly soon render this part of the account out of date.

The numerous keys to the genera, parts of genera, and species form one of the very useful features of the book. These are of particular importance in the large genera, like *Dendrobium*, *Bulbophyllum* and *Eria*, as some of these sectional groups have never been distinguished in this clear manner before. Prof. Holttum takes, on the whole, a rather conservative attitude towards genera, but gives full weight to modern work on the Malaysian monopodial orchids,

in which several of the cumbersome genera have been divided into more natural groups. An excellent key to the genera of this group is provided, based mainly on J. J. Smith's work.

The book is illustrated by four attractive colour-plates of hybrids and more than 230 line-drawings, mostly from the pen of the author. These are especially valuable in showing the diagnostic features of the species and genera figured, besides supplementing the very clear descriptions. For the orchid grower in the tropics there are introductory chapters on the cultivation both of adult plants and of seedlings and, for orchid growers in general, excellent accounts of the main hybrid groups which have been developed in tropical countries. These include *Spathoglottis*, *Dendrobium* and the numerous bigeneric hybrids belonging to the large monopodial group. The latest results are here brought together by one who has been closely associated with much of this hybridization in recent years.

Altogether Prof. Holttum's book provides a very satisfying account of the orchids of Malaya, and will no doubt for long be the standard reference book on this subject.

V. S. SUMMERHAYES

THE ROTHSCHILD COLLECTION OF FLEAS

An Illustrated Catalogue of the Rothschild Collection of Fleas (Siphonaptera)

in the British Museum (Natural History), with Keys and Short Descriptions for the Identification of Families, Genera, Species and Subspecies. By G. H. E. Hopkins and Miriam Rothschild. Vol. 1: Tungidae and Pulicidae. Pp. xv+361+45 plates. (London: British Museum (Natural History), 1953.) 84s.

ALTHOUGH one of the 'smaller orders' of insects (about 1,350 described species and sub-species), the Siphonaptera, or fleas, are the subject of a considerable volume of taxonomic literature, mostly written during the past half-century, or since the role of some species as vectors of bubonic plague was proved. A world list published in 1895 included only thirty-five species. About that time, three entomologists, Julius Wagner in Russia, Carl F. Baker in the United States, and the Hon. N. Charles Rothschild in England, turned their attentions to this virtually neglected group of small and despised insects. All three left their mark in flea taxonomy; but it was Rothschild who amassed what is even to-day the world's most representative collection. Working at first alone but later with his friend and colleague Karl Jordan, Rothschild published numerous descriptions of genera and species that set a standard of definition and accuracy not often excelled to-day. At an early stage Rothschild realized the importance of the collection he was building, and by deed of gift in 1913 arranged that it become the property of the British Museum (Natural History) on his death. According to one of the provisions of the deed, the trustees were to "cause to be made and published a catalogue giving the names and full number of specimens of each species of parasitic insect in the said collection".

The collection became the property of the Museum in 1923, on Rothschild's death; but thirty years were to elapse before the catalogue could be prepared.

The delay has been advantageous in many ways: the collection has continued to grow; numerous new species, genera and other categories have been described; and most important, Karl Jordan, the greatest authority on the order, has had time to study the difficult problems of phylogeny, which had to be considered before a natural classification could be proposed, a task that would have been impractical three decades ago.

The book under review, then, is the first volume (of five) of the promised catalogue, and is the work of G. H. E. Hopkins and the Hon. Miriam Rothschild (daughter of Charles). The authors set themselves three objectives: to fulfil the terms of the deed of gift; to provide keys, descriptive notes and figures to aid in the identification of all known species; and to publish the skeleton classification made by Dr. Jordan. Despite their modest assertions to the contrary, this work will virtually constitute a monograph of the Siphonaptera of the world.

A preface and foreword are followed by an introduction, which defines the scope of the catalogue and gives some particulars about the collection, which now contains about eleven hundred, or more than 80 per cent, of the known species and sub-species, including 682 holotypes and lectotypes of valid forms, as well as numerous paratypes, and types of synonyms.

Of great interest are the provisional phylogenetic tree illustrating Jordan's views on the broad relationships of the seventeen families of fleas, and a table of the valid genera and subgenera, which number about two hundred, with their families and sub-families. An illustrated and annotated glossary, covering twenty pages, will prove most useful, as there has been much non-conformity in interpretation and terminology of flea anatomy; the usage in the present catalogue is therefore defined. This section is followed by keys and the main body of the text.

The authors follow Jordan (1948, in Smart) in considering the Siphonaptera as divisible into two superfamilies, the Pulicoidea (the smaller, and the topic of Vol. 1) and the Ceratophylloidea. The Pulicoidea contain two families, the Tungidae (sub-families Tunginae and Hectopsyllinae) and the Pulicidae (Pulicinae, Archaeopsyllinae, Spilopsyllinae and Xenopsyllinae). In all, 24 genera and 147 species and sub-species are considered to belong to the Pulicoidea. Adequate keys (tested by the reviewer on specimens of about sixty species) and concise descriptions are provided for all categories. The important but difficult genus *Xenopsylla* (fifty-seven species) is broken down into eight species-groups. Locality and host records are limited to material in the collection and examined by the authors. These are arranged geographically according to the regions and sub-regions defined in Bartholomew, Eagle Clarke and Grimshaw's "Atlas of Zoogeography" (1911), an arrangement that is satisfactory for the purposes of the catalogue. Host nomenclature has been revised to conform with the recent works of Ellerman, Peters and others. There is little or no discussion of host relationships or geographical distribution *per se*.

The book is profusely illustrated by line-drawings of the diagnostic structures of the species. There is some lack of uniformity in the figures in that they were prepared by a number of individuals; but they have been well selected and a high standard of quality has been maintained. Forty-five plates of

truly excellent photographs of fleas deserve special mention. These are mostly the work of Arthur Barron and are quite the best and most useful photographs of fleas I have seen. It is to be hoped that the succeeding volumes will be similarly illustrated.

It is understood that Vol. 2, covering seven families (Coptosyllidae, Vermipsyllidae, Stephanoceroidea, Hypeophthalmidae, Ichnopsyllidae, Macroscyllidae and Xiphiopsyllidae) of the Ceratophylloidea is due for publication. The appearance of this and succeeding volumes will be eagerly awaited by all students of fleas. Meanwhile, the authors and publisher may be congratulated on the high quality and practical usefulness of the first volume of a work that will be the standard reference on fleas for many years to come.

G. P. HOLLAND

MATHEMATICAL METHODS

Methods of Theoretical Physics

By Prof. Philip M. Morse and Prof. Herman Feshbach. (International Series in Pure and Applied Physics.) Part 1: Chapters 1 to 8. Pp. xxii+998+xl. Part 2: Chapters 9 to 13. Pp. xviii+999-1978. (London: McGraw-Hill Publishing Company, Ltd., 1953.) 120s. each volume.

THEORETICAL physics to-day has a vast content. To expound fully the mathematical methods which are necessary for the development of the major branches of the subject would be a great undertaking. Authors of text-books on the methods of theoretical physics must therefore choose between covering a very wide variety of methods in a superficial kind of way, and treating a restricted range of topics comprehensively. It is this latter course which Profs. Morse and Feshbach adopt. Despite its general title and its great length, their work consists almost entirely of an exposition of the methods of solving Laplace's equation, Schrödinger's equation, and the scalar wave equation. It is, however, an excellent account of these topics and will doubtless become a standard work.

The first three chapters of Part 1 consist of an account of various types of field (scalar, vector, tensor) occurring in theoretical physics, and of the differential equations and variational principles governing them. This is followed by three chapters on functions of a complex variable, ordinary differential equations and the theory of eigenfunctions, respectively. A great deal of the material in these first six chapters (covering nearly eight hundred pages) is familiar, but it is discussed in a manner particularly suited to the needs of the mathematical physicist. The treatment is always interesting, and sometimes novel—for example, the discussion of the 'Euler' transform in Chapter 5. The last two chapters of the first volume are devoted to the Green's function technique for the solution of partial differential equations, and to the theory of integral equations. The account of the method of Green's functions is particularly clear and attractive.

The second volume begins with an account of the three main approximate methods of solution of boundary value problems in physics: (1) the perturbation method, (2) the variational method, (3) the variation-iterational method. That this chapter is long (more than 170 pages), and difficult, is due largely to the fact that the authors have illustrated

the methods they describe by applying them to difficult and worth-while problems of the kind which a theoretician will encounter in the course of his researches, rather than to the artificial kind of problem one encounters all too often in mathematical treatises. The remainder of the work is devoted to the application of the principles already established to the differential equations of mathematical physics—Laplace's and Poisson's equations, the wave equation, the diffusion equation, Schrödinger's equation. The partial differential equation approach (separable systems) is developed for exact solutions, the integral equation approach for approximate solutions.

From this brief description of the contents of the book it will be seen that it is, as the authors state in the preface, more a treatise on the boundary value problems of mathematical physics than a comprehensive account of mathematical methods. For example, it treats very sketchily, or omits entirely, the theory of characteristics, the flow of fluids, supersonic flow, and the equations governing the behaviour of solid continua. It does not develop either the theory of groups or the theory of matrices, both of which are of great use in theoretical physics. Nor is the use of dyadics rather than tensors a very happy choice. But within their limited field the authors have produced a work which, both on account of the amount of physics and the rigour of the mathematics, is very nearly complete and self-contained.

The striking feature of the whole work is the clarity of the exposition. Difficulties are not avoided or treated superficially. Little attempt has been made to compress the material; this may have led to a book of great length, but it has also produced one of great value. As has already been indicated, the physical problems which the authors discuss have been chosen for their current interest, and are seldom trivial. No attempt has been made to produce solutions from 'thin air'—the problems are tackled in a systematic way which not only illustrates the basic points of the theory, but also helps the young research worker to acquire a body of technique sufficient to enable him to grapple with the problems he encounters in the course of his researches. Running through the book is the view that very few problems in mathematical physics are capable of exact solution, so that the student must acquire facility in deriving approximate solutions. The approximate methods which the authors develop are analytical in nature. The fact that they do not discuss purely numerical techniques, such as 'relaxation', is not a serious drawback, since there are already in existence several admirable accounts of these methods.

The standard of book production is well up to the excellence of the authors' writing. The printing, the lay-out and the illustrations of the book are of an exceptionally high quality, and make it a pleasure to use. The book's one disadvantage is one which will not have escaped the publishers: its high price (£12 for two volumes) makes it impossible for all but a very few students to possess it. It is difficult to see how a book of this length could have been other than expensive; but it is a pity that it cannot be readily available to students. It should, of course, be in the library of every mathematical department. It will not lie undisturbed upon the shelves, for it contains a very great deal which will be of value to all who have to learn (or have to teach) mathematical physics.

I. N. SNEEDON

The Yearbook of the Universities of the Commonwealth, 1954

Edited by Dr. J. F. Foster. (Thirty-first issue.) Pp. lviii+1916. (London: Association of Universities of the British Commonwealth, 1954.) 63s.

ONCE again the Association of Universities of the British Commonwealth has produced its "Yearbook". This year's edition is more than a hundred pages longer than the last one, but remains at the same price.

The only additional complete entry for an institution this year is the Nova Scotia Agricultural College; but mention is made of the establishment in July 1953 of a second university in East Pakistan, the University of Rajshahi, and of Rhodesia University College, Salisbury, and it is hoped to have full entries for these in next year's edition. Of the other new material, the introduction for the universities in Australia has been specially rewritten by the Secretary of the Australian Vice-Chancellor's Committee, and a fuller statement is included of the history and functions of the Association of Universities of the British Commonwealth. In addition, an attempt has been made for the first time this year to give for each university and university college in the United Kingdom a short statistical note of the numbers of its students who come from other countries.

Besides the various national sections with the staff lists for each of their university institutions, the usual host of information is to be found in the nine appendixes. The alphabetical list of names contains more than thirty thousand entries. Once again the important point must be emphasized that this book records all the university institutions of the British Commonwealth and not merely those—the majority, in fact—that are members of the Association of Universities of the British Commonwealth. Indeed, in one of the appendixes are the respective lists for the universities in the Republic of Ireland. The point is well made in the preface that, although this book is not international in the comprehensive world-wide sense, it covers such a large part of the globe and includes such a diversity of countries and races that it must surely rank as one of the leading international works of reference about universities.

Vulkanismus und andere Tiefenkräfte der Erde

Von Carl Chr. Beringer. (Kosmos Bändchen No. 200.) Pp. 64. (Stuttgart: Kosmos-Gesellschaft der Naturfreunde, 1953.) n.p.

THIS booklet is one of a series designed to make a popular appeal to various subjects in science and natural history. The title is somewhat misleading, since the first fifty-two of its sixty-four pages are devoted entirely to a condensed account of the main modern volcanic eruptions, their types and distribution. It is well illustrated with plates and diagrams, though the map of the world (frontispiece) oddly omits the British Isles. The phenomena of fissure-eruptions, plateau-basalts and pillow-lavas receive but scant attention, and the relationship of the acid or basic composition of the lavas to the types of eruption is not made clear.

The second part of the book, which attempts to deal with the other deep-seated agencies in the earth's crust in a dozen pages, not unnaturally fails. It includes a short description of bathyliths, the hypothesis of shells surrounding a nickel-iron core and a note on supposed convection currents within

it; the barest mention of continental drift, radioactivity, geosynclines, orogeny and earthquakes; and expresses the belief that volcanic activity is steadily waning through the passage of geological time.

The bibliography contains a list of seventeen authors, seven of them in the nineteenth century from 1808 upwards; the only reference in English is dated 1825. Surely in 1953 a representative and up-to-date conspectus of the principal literature could have been included?

The booklet is well printed in Roman characters, on paper which seems equally suitable for text and plates. It would serve its purpose far better were the title restricted to vulcanology with more generous treatment, while discarding the unsatisfactory tail-piece. This could well be developed into a companion volume on geophysics and dynamics.

D. W. BISHOPP

From an Antique Land

Ancient and Modern in the Middle East. By Dr. Julian Huxley. Pp. 310+49 plates. (London: Max Parrish and Co., Ltd., 1954.) 25s. net.

THIS is a delightful book and as a record of travel in the post-war Middle East is outstanding in its merits. The author, travelling on the affairs of Unesco, visited and recorded his impressions of nearly every place of importance which is readily accessible. Even places with which a reader is perhaps very familiar assume a new interest when viewed through the author's inquiring eyes; and almost equally so when seen through the lens of his camera. The photographic illustrations, many of them in colour, are superb, and we can only regret that there are not more of them.

In his introduction, the author modestly claims that even after his wide and hurried travels and his study of the works of authorities, his knowledge remains "extremely scrappy". If this is so, his marshalling and analysis of his scrappy knowledge is most satisfactory; and his chapter on the birth of civilization is, in the writer's view, masterly. It is only when we read an essay such as this that we can fully realize the vast accumulation of historical fact that has been laid bare by the archaeologist during the past half-century.

To any prospective traveller in the Middle East countries, this book should prove invaluable reading prior to his journey; and even more interesting entertainment on his return.

W. B. EMBRY

Metallurgical Abstracts

(General and Non-Ferrous). Edited by N. B. Vaughan. Vol. 18, 1950-51 (New Series). Pp. viii+925. (London: Institute of Metals, 1951.)

THIS volume for 1950-51 of "Metallurgical Abstracts" maintains the high standard set by the Institute of Metals and should be invaluable to all metallurgists. The writing is in general clear and good; but more concise phrasing would result in a saving of several lines per page without any loss of subject-matter, and would avoid the necessity of unpleasant abbreviations, such as 'temp.' for temperature, which spoil the appearance of the volume. It may be suggested that, in view of the knowledge of English in so many countries, the abstracts would be of more value if a greater proportion of the space were given to the more important papers in the obscurer languages.

W. HUMPHREY

CHANGES IN WORLD GLACIATION

A GEOPHYSICAL Discussion of the Royal Astronomical Society in conjunction with the British Glaciological Society was held at Burlington House, London, on January 29, the subject being "Changes in World Glaciation". The principal speakers were as follow: Prof. F. E. Zeuner (Institute of Archaeology, University of London), Dr. J. D. H. Wiseman (British Museum (Natural History), London), Prof. G. Manley (Bedford College, London) and Mr. F. Hoyle (St. John's College, Cambridge), in that order. Mr. Gerald Seligman, president of the British Glaciological Society, was in the chair.

Without doubt such a subject of discussion ranks with several others of a cheerfully provocative kind in which it is not given to any one group of scientists to provide the answer. In a sense, such major issues offer not only a meeting-ground but also a much-welcomed stimulus. It has long been proverbial that he who wants to set a university by the ears with the view of encouraging the students can scarcely do better than arrange a symposium on such subjects as submarine canyons or cloud physics. In a symposium on climatic change the geologist busy with his muds lifts his eyes again to the stars; the astronomer is suddenly reminded that he must bring down his time-scale to cope with the mundane requirements of the botanist; the environmental archaeologist seeks more fundamental reasons for the pathetic squalor of his kitchen-middens. The physicist is led to reconsider the yielding of masses of ice under varying conditions of temperature; and the meteorologist, eternally distracted by the hourly irregularities of his elusive goddess, begins to wonder whether her pattern of behaviour can be led to display a major alteration through gentle persuasion or through sudden blows.

Opening the meeting, Mr. Seligman referred to the need for further work on the causes of changes in world glaciation, whether within the earth's system or without, and directed attention to Dr. H. W. Ahlmann's emphasis on the great value of such studies in the interrelation of the sciences. A large and highly diversified audience attended; but it became evident that co-ordination of the approaches made by workers in several fields is still not easy, and a two-hour meeting on such a vast subject could but leave the appetite whetted.

Prof. Zeuner began by very appropriately stressing the need for further collection of facts. He believed that the integration of evidence both in space and time is first necessary, and the new techniques of dating successions for purposes of correlation are still in an early stage. He demonstrated the complexity of the problem of glaciation in relation to the evidence for eustatic changes of sea-level in the Pleistocene in those areas which might reasonably be deemed free of isostatic complications. Quite apart from the effects of the several successive phases of the Ice Age, there appears to have been an overall lowering of sea-level during the past million years or so throughout southern and south-western Europe. If that is so, the relationships between large-scale terrestrial changes, presumably of tectonic origin, and glaciation is not simple and requires further elucidation. With the aid of a diagram he pointed out that in the Post-Glacial the prevailing rate of

fall of sea-level relative to the land underwent what might perhaps be rhythmic fluctuations with a period of the order of 1,800-2,000 years, a fact deduced from close studies of the Thames terraces and of numerous beach-levels. The relationship of such fluctuations to variations in the tectonic forces at work or to variation in the rate of melting of ice-caps is still open to discussion.

Dr. Wiseman gave a brief but critical account of the recent results he and his colleagues have obtained from a close study of cores, collected in the equatorial Atlantic Ocean by the Swedish Deep-Sea Expedition, 1947-48, under the leadership of Prof. Hans Pettersson. Although Dr. Wiseman has recently published a preliminary paper², work is still in progress and some exciting glimpses of these new results were given to the meeting. It is apparently possible, in suitable deep-sea cores where specified conditions have been satisfied, to determine the past temperature changes in the upper layer of the sea by three different methods.

The first method is to determine the mass contribution of calcium carbonate per c.c. per year in a series of sections throughout the length of the core; the second method is to determine the species distribution of planktonic foraminifera; and the third to determine the oxygen-18 content in specific planktonic foraminifera. A core nearly 14½ m. in length has been investigated at every 5 cm., and more detailed investigations have been carried out on a series of sections taken continuously down a short pilot core. The graph showing the yearly mass of calcium carbonate deposited per c.c. in the short pilot core shows a series of minor oscillations superimposed on a major curve. There is an apparent correlation between these minor oscillations and the known minor climatic oscillations of more temperate regions. Dr. Wiseman pointed out that the conclusions arrived at from the rate of sedimentation of calcium carbonate were supported by the species distribution of planktonic foraminifera as well as by the oxygen-18 determinations on specific planktonic species carried out by Dr. Emiliani. For example, where the yearly rate of sedimentation of calcium carbonate is relatively high—namely, 990 µgm./sq. cm.—the calcareous tests of *Globigerinoides sacculifera* were apparently deposited at 24.8° C., while at a depth of 26.3 cm. from the top of the core where the yearly rate of sedimentation of calcium carbonate has fallen to 330 µgm./sq. cm. the tests of *Globigerinoides sacculifera* were deposited at 20.1° C.

Dr. Wiseman has found it possible to make age determinations by three different methods. The sources of error were briefly mentioned, and much work has and is still being carried out to show the justification of certain basic assumptions. It is of great interest to note that the minor oscillations in the rate of sedimentation of calcium carbonate are apparently synchronous with the minor climatic oscillations of more temperate latitudes. For example, at a depth of 22.4 cm. corresponding to an age of 9300 B.C., there is a minor oscillation in the rate of sedimentation of calcium carbonate. This oscillation would seem to be synchronous with the Allerød oscillation in Denmark⁴, the age of which

according to recent carbon-14 measurements is 8800-9900 B.C.

Dr. Wiseman stressed the necessity for more work of this nature, and was careful to point out that the techniques used are not applicable to all cores, but can only be used where suitable conditions of sedimentation have existed. Finally, he showed a chart giving the many localities in the Atlantic where foraminiferal analysis has revealed cooler conditions in the past in the upper layer of the sea; and he pointed out that in four nearby cores collected from the Equatorial Atlantic, Dr. D. B. Ericson⁸ has recently been able to make correlations from core to core and has concluded that the deposition is continuous and normal, and that there is no obvious evidence of turbidity currents, erosion, slumping or re-worked older sediments.

Prof. Manley emphasized the need for more attention not to the mere existence of ice but to the changes in its extent. Referring to the advances and retreats during the past three centuries, it is clear that a marked degree of parallelism existed around the North Atlantic, shown by the series of curves from numerous sources in several countries which have been assembled by Dr. H. W. Ahlmann in his recent Bowman Lecture⁹. With a further diagram he showed that the overall agreement between the fluctuations of the southern Icelandic glaciers and what is known of the fluctuations of the mean summer temperature in England¹⁰ is temptingly attractive. The eccentric position of the Pleistocene glaciation in the northern hemisphere on either side of the Atlantic suggests that the key to the greater events of the past may well lie in studies around that ocean. Whatever other causes are sought, changes in the configuration, depth and surface temperature of the North Atlantic are still deserving of further consideration, and Prof. Manley said that he was glad Prof. Zeuner had directed attention to the same problem in another way. He went on to demonstrate the minor irregular fluctuations of the order of two to three decades in length which have also been recognized in tree-ring series and other annual deposits. While these may reflect small changes in the character of the general circulation of the atmosphere, they have all occurred in the presence of a warm North Atlantic. The greater phenomena of the past and especially the low snow-line in the Ice Age require a much cooler ocean off north-western Europe⁷; and, as the development of the greater glaciations took a long time, perhaps of the order of two to three thousand years, the sea surface must have been cooled well before the maximum of glaciation, and we should decide how this could happen. He gave reasons for the opinion that each of the minor Late-Glacial re-advances in Britain was preceded by a fall of temperature of the same order as that which sufficed for the maintenance of maximum glaciation, but lasting for a much shorter time. A very rough calculation based on the size of the revived Post-Altered glaciers in the Lake District in England appears to indicate that fifty to a hundred years would suffice for the re-advance, after which the ice lasted for four centuries or so. It would therefore appear that each of the changes in glaciation represented by advance could have taken place relatively rapidly and that they were succeeded by a much longer stage of stagnation or slow retreat. If that were so, we are faced with the problem of explaining why the pattern of the world's atmospheric circulation could be displaced, or biased,

from its present state for varying lengths of time, and why patterns which are now merely ephemeral could become more persistent.

Mr. Hoyle developed a new line; he thought that the change in the amount and character of world glaciation in the period from the Late-Glacial to the Climatic Optimum represents a climatic change so remarkable as to be outside the operation of the earth's meteorological system. Astronomers are not happy about such rapid changes in solar variation, and he referred to the other type of external influence which might result from local variations in the density of interstellar matter between sun and earth. Such effects, which he had outlined in earlier discussions¹¹, are now calculable and cannot now be allowed as sufficient. Solar radiation might otherwise become intensified by the picking-up by the sun of material from interstellar clouds; but as the sun would need to move very slowly through such clouds it would not be able to do so sufficiently often to explain the observed effects. He thought that the recent work by Dr. E. G. Bowen in Australia¹² reopens the position completely. Bowen has studied the remarkable tendency for intensification of rainfall on certain days of the year in Australia; this is now confirmed elsewhere in the southern hemisphere, and also in Britain, and it is also related to the observations of noctilucent clouds. The possibility exists that this results from the provision of nuclei arising from the incidence of showers of meteoric dust at particular seasons and falling to the right levels. Mr. Hoyle therefore suggested that one of the most satisfactory ways of changing climate would be to tamper with the 'greenhouse effect' through knocking out some of the water vapour; and that the necessary material might be provided by the breaking-up of a particularly large comet. The figures for the mean mass of comets are, he said, in agreement with this possibility, and the particles providing the zodiacal light are of the right size. Alternative explanation can still be sought in changes of the rate of movement of a gas passing through the solar system.

Subsequent speakers were much exercised by Mr. Hoyle's suggestions, and Mr. D. J. Schove asked if any evidence could be obtained from deep-sea sediments of variations in the abundance of such meteoric material. Dr. Wiseman replied that work is in progress on the nickel and cobalt content of deep-sea cores, and it is hoped that it will shortly be possible to decide whether the nickel was or was not of cosmic origin. Mr. E. Gold asked if anything is known of the effects of other meteoric streams—for example, those in August—and thought there is very little water vapour at the great heights mentioned; Mr. Hoyle thought that the time of sinking of the fine particles through the atmosphere might vary and could be of the order of twenty days.

The discussion was perforce, like many of its kind, inconclusive; but the numerous problems brought to light go far to show that although the issues are being gradually narrowed we still need more exact knowledge of what we are trying to explain; and, indeed, the problem of climatic change is increasing in complexity. Prof. Zeuner's contribution calls to mind the need to avoid the uncritical reliance on the results of changes in the extent of land and sea and of the relief in high latitudes; subsequent re-emphasis of the character of the open North Atlantic in relation to the location of the continental ice-sheets raises the question of how, and over what

length of time, cooling took place, an answer to which must await the work of Dr. Wiesman and his colleagues. There is evident need for further investigation of the extremes of climatic displacement which have resulted at various times in different parts of the world. The fact of the snow-line having been by no means uniformly lowered over the world as a whole, and the very variable length of the glacial phases, needs further study. The meteorologist is well capable of outlining pressure maps for the Ice Age; the importance now lies in the process by which transition was effected, and further evidence, from the field sciences, of the time required for such transitions may enable the meteorologist to provide an answer. The challenge of Mr. Hoyle's statement, that the change from Glacial to Climatic Optimum lies outside the operation of the earth's meteorological system, is one which will unquestionably stimulate further thought. Even the man of science on his Alpine holiday can reflect upon the conspicuous results of the seventy-odd years of decline of the Rhône glacier as a possible portent.

NEW INSTITUTE OF CLINICAL SCIENCE AT THE QUEEN'S UNIVERSITY, BELFAST

THE Institute of Clinical Science of the Belfast Medical School was opened recently on behalf of the Duchess of Gloucester by Lord Wakehurst, the Governor of Northern Ireland. The purpose of the

new Institute is to provide additional room for teaching and to increase the research facilities of the school. Owing to certain building restrictions, it was necessary to divide the building so that the Institute consists of two buildings united by a closed-in bridge.

The west block contains two large lecture theatres capable of seating 282 and 221. In these, special attention has been given to acoustics, and a very efficient and pleasing result has been obtained. They are mechanically ventilated and furnished with modern projection apparatus of various types. Teaching facilities are also supplied in eight tutorial rooms, each capable of seating thirty students, and furnished with projection and other apparatus for demonstration. The west block also contains the Departments of Therapeutics, Obstetrics and Gynaecology, Child Health and Social and Preventive Medicine, as well as a photographic unit and an artist's studio.

The Medical Library is also in the west block. It has been provided as a War memorial, and in addition to the main reading rooms has three separate reading rooms for undergraduates, postgraduates and staff, which serve as memorials to three young graduates who fell in the Second World War. These rooms are panelled in various woods, and the main room contains six paintings by Mr. Norman Wilkinson, depicting the counties of Northern Ireland. This building is linked to the Institute of Pathology and to the teaching wards of the Royal Victoria Hospital.

The east block contains the Departments of Medicine and Surgery. The third floor is designed for experimental research. Each member of staff has a private laboratory, while in addition each department has at least one communal laboratory. A great deal of thought has been given to the services for the whole building, and these are earned in the ceilings of the corridors; but they are readily accessible above the false ceilings and can be easily expanded to meet further developments. This distribution of the services renders maintenance a relatively easy matter.

The link with the hospital, and the provision of lifts, render it possible for a patient in bed to be wheeled to any floor for detailed investigation.

The architects have been successful in producing a pleasing exterior by using multicoloured Ravenhead russet brick and Portland stone. The windows, which are double for heat conservation, are in good proportion to the mass of the building. In all, the architects have succeeded in their aim and have provided a dignified building for the undergraduate, and excellent accommodation and facilities for the research work of the staff.

THE TWO VISCOSITIES OF FLUIDS

A ROYAL SOCIETY discussion on "The First and Second Viscosities of Fluids" was held in the rooms of the Society, Burlington House, on April 29.

The discussion was opened by Prof. L. Rosenhead (Liverpool), who reviewed the fundamental facts and concepts. The generally assumed relationships between the stresses and rates of deformation in a homogeneous fluid lead to equations such as:

$$p_{xx} = -p + \mu \left(\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} \right) + 2\mu' \frac{\partial u}{\partial x} \quad (1)$$

$$p_{yz} = \mu \left(\frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \right), \quad (2)$$

where u , v and w are the components of velocity referred to fixed orthogonal axes Ox , Oy , Oz ; p_{xx} , p_{yz} components of the stress tensor, μ the first (or shear) coefficient of viscosity and μ' the second (or dilatational) coefficient of viscosity. The combination $(\mu' + \frac{1}{3}\mu)$, denoted by κ , is the bulk viscosity.

The physical meaning of μ is evident from equation (2), but that of μ' depends on the interpretation of p in equation (1). In the past the bulk viscosity has either been ignored, for which there is some justification if incompressible fluids are being considered, or it has been assumed to be zero, which is true if p is equal to $-(p_{xx} + p_{yy} + p_{zz})/3$. If, however, p is not equal to this last expression, there is no *a priori* reason for assuming $\kappa = 0$, and its actual value (and hence the value of μ') is open to experimental investigation for any given interpretation of p . Up to the present, the value of κ has not been measured directly, but values of κ/μ have been deduced independently from the results of two different types of experiment—the absorption of sound-energy and the determination of the speed of acoustic streaming. In both cases p is taken as the thermodynamic pressure, defined at constant entropy as a function of ρ . The former type of experiment is well established, but the latter field was opened up recently by the theory of Eckart¹ and the experiments of Liebermann². Liebermann concluded that there is reasonable agreement between values obtained by the two techniques. It was found that, at megacycle frequencies, κ/μ is nearly zero for gases and liquefied gases, is 'small' (say 0.5) for bonded liquids, such as water and the alcohols, is larger (5–20) for most organic liquids and largest for a group of non-polar liquids including carbon tetrachloride, benzene and carbon disulphide. The last-named substance has the highest known value with $\kappa/\mu = 200$ at room temperatures.

These facts, however, merely provide a start, and a number of problems remain. From equations (1) and (2) it can be deduced that the sound absorption coefficient α is proportional to the square of the

frequency. This is not always found (for example, with carbon disulphide and acetic acid), and deviations are often explained in terms of a 'relaxation' theory. What then is the significance to be attached to p and μ' in equation (1), and how is the theory of acoustic streaming to be modified? Further, there is some doubt about certain aspects of the technique employed by Liebermann for measuring the streaming velocities; this is partly connected with questions of interpretation of results and partly with difficulties intrinsic in the technique.

Experimental questions concerning acoustic streaming were discussed by E. G. Richardson (Newcastle upon Tyne). He recalled that streaming was first recorded with sonic sources by Dvořák³ and afterwards investigated by Rayleigh⁴, Andrade⁵ and Schlichting⁶, who showed that at low frequencies the effect is due to vorticity generated in the boundary layer. Under these conditions recent experiments at Newcastle show that, if the temperature is varied, streaming appears to increase with decreasing viscosity. This also appears to remain true in the megacycle region, even for substances with large bulk viscosity. It was said that dissipative heating of the medium seems to be due to shear viscosity only, and that experiments on absorption of sound in capillaries can be explained in terms of the boundary effects, which are due only to shear viscosity. Richardson suggested that in view of the high vapour pressures of substances with large bulk viscosity, the possibility that cavitation plays a part in the streaming should be kept in mind. In connexion with this point, Prof. P. Biquard (Paris) remarked that, in order to investigate the effect of pressure and the possible effect of cavitation, he has experimented with various liquids at pressures up to about 100 atmospheres by measuring the scattering of light. The results show that absorption of energy under pressure can be accounted for quite simply by taking into account the percentage variation of viscosity with pressure. The question was also raised as to whether the absorption coefficient depends on the amplitude of the source and the hydrostatic pressure. The replies seemed to indicate that the reported measurements made with continuous waves, using pressure-vane techniques, do show a variation with amplitude, but those made with pulsed waves do not. Increase of pressure has been observed to diminish the absorption in carbon tetrachloride and toluene; but this may be ascribed, in part, to changes in the first coefficient of viscosity and the velocity of sound, both of which enter into the Stokes absorption formula.

S. M. Karim (Karachi) mentioned the work he has recently carried out on the Liebermann type of experiment. He pointed out that the values obtained for μ'/μ sometimes appear to depend on the intensity of the sound beam, probably on account of the development of turbulence. Further, the choice of the ratio of the diameter of the sound beam to that of the tube influences the experimental results. Additional detailed experimental work is required before firm conclusions can be drawn.

The difficulties of separating boundary layer effects from Eckart streaming were emphasized by P. E. Doak (Manchester), who went on to show how Eckart's original theory can be extended to deal with relaxing media while still neglecting boundary effects. He reached the conclusion that, apart from a term in the viscosity gradient, the streaming velocity is in all cases proportional to the coefficient

of sound-absorption. Further, it appears that the streaming is generated by interaction between the stationary and the radiative parts of the acoustic field. If either should disappear, or if the motion is one-dimensional, no streaming is possible. Although this work was based on the notion of vorticity sources, the conclusion concerning the role of sound absorption was also demonstrated by J. E. Piercy and J. Lamb (London). They considered the propagation of a sound beam along the axis of a tube. Due to attenuation, there will be a gradient of radiation pressure proportional to the absorption coefficient, and this can be taken as a body force acting on the fluid—which can now be regarded as incompressible. Starting from this point of view, the velocity profile can be found explicitly in mathematical form. Apparatus embodying this principle has been constructed; it aims at a direct measurement of the radiation pressure of the beam, together with a measurement of the pressure-head generated by a known length of beam. Preliminary measurements at 1 Mc./s. and 25° C. show excellent agreement with other techniques for relative values of $(\alpha/\rho) \times 10^{17}$ ranging from 24 (water) to 5,500 (carbon disulphide).

Both P. E. Doak and R. O. Davies (London) emphasized the fact (due to Mandelstam and Leontovich) that there is no way of distinguishing the effects of a bulk viscosity and a relaxation process associated with frequencies much higher than those of the experiment. The latter author formulated equations of hydrodynamics applicable in a relaxation region and developed the plane-wave solution in order to demonstrate the conclusion just noted. He showed that the presence of relaxation modifies the classical contributions to absorption due to thermal conductivity and shear viscosity. Apart from relaxation associated with intra-molecular vibrational motion (which seems to be present in all liquids with $\kappa/\mu > 20$) there are contributions to the absorption coefficient due to structural changes and shear relaxation which can be investigated experimentally only by working at frequencies comparable with the inverse Maxwell relaxation time.

This aspect of the problem was elaborated by J. Meixner (Aachen), who showed that a liquid can be considered as the limiting case of an elastic body with 'after-effects'. The after-effect theory, when applied to a generalized stress-strain relation containing temperature and entropy, yields an apparent viscosity matrix whose main components become the first and second viscosity coefficients when the substance is isotropic. It is only under certain restrictions that arbitrary after-effect behaviour can be represented as a thermodynamic relaxation theory. When these restrictions are satisfied, parameters referring to shear and volume changes can be separated.

Underlining the fact that stationary transport is to be considered as a limiting case of relaxation, H. O. Kneser (Stuttgart) discussed shear flow and volume flow in gases. In the former case momentum parallel to a wall moving in its own plane is transferred perpendicularly to it with no energy change. The relaxation time is therefore comparable with the collision time and has not yet been observed. When, on the other hand, the wall moves perpendicularly to itself, momentum transfer is coupled with energy transfer and the attainment of a stationary state may be delayed if the molecules have internal mechanisms for storing energy.

J. H. Andrade (Welwyn) and J. Lamb reported further details concerning the intra-molecular relaxation of carbon disulphide centred around 75 Mc./s. at 25° C. and 31 Mc./s. at -63° C. They gave a relaxation theory of absorption involving an arbitrary number of relaxation processes, and then separated effects due to relaxation times much larger and much smaller than the inverse frequency-range of interest. It was suggested that the total magnitude of the volume relaxation still remaining unexplained at 200 Mc./s. can be estimated by assuming that for $f \rightarrow \infty$, $C_v \rightarrow 5R/2$ and $C_p \rightarrow 3R/2$.

Adopting an approach different from that of both the thermodynamic and the molecular theories, Sir Geoffrey Taylor presented a simple mathematical model which exhibits characteristics of a bulk viscosity. He supposes that small gas bubbles are dispersed in an incompressible liquid of shear viscosity μ , thus making the medium as a whole slightly compressible. The contraction and expansion of the bubbles are resisted by the viscosity of the surrounding fluid, and it is found that the second coefficient of viscosity is $4\mu/3v$, where v is the (small) proportion of the total volume occupied by the bubbles.

J. G. Oldroyd (Swansea) said that the quantities p and μ' in the basic equations of Prof. Rosenhead's presentation can, in certain special circumstances, be given precise meanings; but this involves the assumption that the values of the quantities are their 'instantaneous' ones.

In summing up the discussion, Prof. E. N. da C. Andrade remarked that the last time he had heard of the second coefficient of viscosity was when he was a student. The late Prof. Karl Pearson had introduced it into his lectures—only to evict it as quickly as possible; it now appeared to be a topic worthy of serious consideration. He pointed out that the second coefficient (μ') has not been defined in a physical way. But the bulk coefficient (κ)—the quantity used by Sir Geoffrey Taylor in his contribution—is so defined. A method of measuring μ' directly is very desirable. The experiments which had been described fell into two classes—those concerned with absorption and those concerned with streaming. From these the ratio μ'/μ has been determined. It is clear, he said, that there are two types of streaming: the type investigated by Schlichting, Andrade and others, and the type which the Liebermann experiment was designed to investigate. There are a number of faults in Liebermann's apparatus, however, which seem to have been eliminated in the excellent experiments of Piercy and Lamb. Richardson had noted that, of the various liquids he used, the five which exhibit marked streaming also possess higher vapour pressures. It appears to be more significant, however, that four of these liquids are non-polar while the fifth possesses only a small dipole moment. As regards absorption of energy in experiments in capillary tubes, Richardson had mentioned that it seems to be chiefly explained by the first coefficient; but this is to be expected, since the skin-friction effect, which involves shearing motion, will predominate in the experiments, so that the second coefficient will not be able to play a large part. The discussion had clarified the two theoretical methods of approach (one based on a formal mathematical presentation and another based on the physical relaxation theory), and it may now be possible to present relaxation theories in terms of formal mathematics. It does not appear strange, he said, that we understand so

little about the second coefficient of viscosity when we realize how little we know about the first. We appear to be at the beginning of a very important study of the internal vibrations of molecules, leading, it is hoped, to a clarification of the fundamental concepts of fluid dynamics. Prof. Andrade stressed the importance of choosing the best fluids for experimental and theoretical work; water is most unsuitable, as it has a wide variety of abnormal characteristics.

A full report of the meeting will appear in the *Proceedings of the Royal Society* in due course.

OBITUARIES

Dr. E. M. Elderton

ETHEL MARY ELDETON was born on December 31, 1878, and died on May 5, 1954. She entered Bedford College for Women in 1895 in the Faculty of Arts and went down in 1899 without having sat for a degree. University was followed by a period of teaching; but the real pattern of her life-work did not emerge until about 1905, when through Alice Lee she worked first for Leonard Darwin and then for Francis Galton, being made secretary of the Eugenics Record Office in 1906. From this modest beginning she became successively Galton Scholar, Galton Fellow, assistant professor and reader in eugenics in University College, London (1931). She retired in 1935.

During the whole of the period in which she was either attached to, or a member of, University College she was actively engaged in both teaching and research. At the College she was a member of a research team headed by Karl Pearson, and as such much of the work she did was contained in the co-operative effort; but evidence that she was capable of a sustained piece of individual research will be found in such a memoir as "Report on the English Birth Rate 1914", to quote only one of a number of publications with a eugenic flavour.

As a person she was delightful, as an expositor she was unrivalled for clarity of thought and lucidity of

expression, and as a teacher she had the rare gift of enthusiasm and the ability to impart it to others. There must be many to-day who owe to her their first steps in statistics and the knowledge and self-confidence that things were not so difficult as more mathematically minded teachers had made them appear. Her essential modesty hid an ability which caused the first Galton Fellow to write in 1906: "Miss Elderton has certainly been a remarkable success at the Eugenics Office; but I think her marvellous energy and quickness to learn anything new would have enabled her to succeed at anything she undertook".

Her work was recognized by the award of the Weldon Medal in 1919, and in December 1931 the University of London conferred on her the degree of D.Sc.

F. N. DAVID

Dr. W. T. Mathias

WILLIAM T. MATHIAS, lecturer in botany in the University of Liverpool, suffered a heart attack in his laboratory on May 19, and died in hospital an hour or so later. This was a severe blow and shock to his family and friends, for only the previous day he had taken the senior students on a field excursion to North Wales.

He was born in Cardigan, South Wales, in 1900, and graduated in agriculture from the University College, Aberystwyth, in 1922. He then specialized in botany. Although offered a scholarship for research at Oxford, he chose to go to Bangor as an assistant lecturer under Prof. D. Thoday; but a year later, in 1924, he moved to the Botany Department of the University of Liverpool. His early training under Prof. Lloyd Williams led to an interest in the problems associated with the life-cycles of marine algae, and Mathias's published researches on *Callithamnion* and *Phloeoispora* were in this field. For some years past he had been making a similar study of *Chordaria*.

Mathias was an enthusiastic and willing teacher, and always carried a large share of the teaching load of the Department. He took an active part in extramural work and in school examining, still finding time to help and encourage amateurs in their field collecting. He was for some years secretary of the University Military Education Committee, and took a very keen interest in the welfare and progress of the units associated with the University.

He is survived by a widow and two children; in 1931 he had married Miss Jane Evans, who was one of his former students at Bangor.

ALAN BURGESS

NEWS and VIEWS

The Kalunga Prize: Mr. Waldemar Kaempffert

THIS year the Kalunga Prize, which is awarded annually by a panel of judges appointed by Unesco, has gone to Waldemar Kaempffert, who has been science editor of the *New York Times* since 1927 except for the short spell which he spent as director of Chicago's Museum of Science and Industry. Born in New York City in 1877, he is universally regarded as the dean of American science writers. His long and distinguished career has included the editorship of *Scientific American* and *Popular Science Monthly*.

He has written a number of books; but by far the most important part of his life's work has been his writing for the *New York Times*, his regular articles in the *Sunday New York Times Magazine* being particularly popular among laymen and scientists alike. "Current Biography" has justly summed up his career in these words: "No one has done more to bridge the gap between the abstract hypotheses of the laboratory and the mind of the common man". The award will be accepted everywhere as an excellent choice and as a tribute to the great importance of the profession of science writing nowadays. It reflects

the change in the conditions of award whereby the Kalunga Prize now becomes a mark of recognition for "a distinguished career of public service in the interpretation of science". It is interesting that the nomination which brought Mr. Kaempfert's name before this year's judges came from the Association of *British Science Writers*, which exists to improve the standards of science writing in Great Britain. Mr. Kaempfert's views on the present state of the press relations of science were vigorously expressed in a recent number of the *Bulletin of the Atomic Scientists* (November 1953) in an article headed "Neither is Perfect".

Department of Genetics of the University of Sheffield

THE recent establishment of a separate Department of Genetics in the University of Sheffield is the logical development of the stimulus given to this subject in the Departments of Botany and Zoology when Dr. J. M. Thoday was appointed as lecturer in cytogenetics in 1947. In addition to the immediate impact of the teaching of genetics on the two parent Departments, the subject has an increasing importance in shedding new light on biological problems at all levels. This has been emphasized by courses given in medical and microbiological departments and by the steady growth of a thriving research school. The independence accorded to genetics in Sheffield now makes possible extensions into wider fields without interfering with the teaching of genetics as hitherto to students of botany and zoology. While Dr. Thoday's research interests are varied, they have perhaps expressed themselves most prominently in investigating the effects of ionizing radiations on chromosome structural changes and the further influence of environmental factors on the frequency of these changes. In setting up the new Department, the University has recognized the rightful independence of a subject which cuts across the formal frontiers of long-standing subjects like anatomy, botany, physiology and zoology. That it has been thought fit to appoint Dr. Thoday as senior lecturer in charge is a testimony to his ingenuity as a research worker, his inspiration as a teacher and his insight as a supervisor of research.

Centenary of Boole's "The Laws of Thought"

THE centenary of the publication of the "Laws of Thought" by George Boole was celebrated at the Royal Irish Academy, Dublin, during May 24-25. The "Laws of Thought" was published in 1854 while Boole was professor of mathematics in Queen's College, Cork; but his association with the Royal Irish Academy had begun ten years earlier when his friendship with the Rev. Charles Graves led him to use the *Proceedings and Transactions* of the Academy as a medium for the publication of some of his papers. At the recent meeting in Dublin the guests included Prof. L. E. J. Brouwer (Blaricum, Holland), T. L. Craven (Automatic Telephone Co., Liverpool), W. C. Kneale (Exeter College, Oxford), Rush Rhees (University College, Swansea), Prof. J. B. Rosser (Cornell University), Sir Geoffrey Taylor, and the Rev. Ivo Thomas (Hawkesyard Priory, Staffs). The afternoon of May 24 was devoted to a formal celebration, when Sir Geoffrey Taylor, a grandson of Boole, spoke on George Boole and his family connections, and the Rev. Canon Feys gave an address entitled "Boole's Achievement in Developing Symbolic Logic". On the morning of each day there was

a technical session at which the following papers were read: F. E. Hackett, the Method of George Boole; J. B. Rosser, Boole and the Concept of Function; T. L. Craven, Boolean Algebra and Switching Current Design; Rev. Ivo Thomas, Boole's Concept of Science; Rev. Canon Feys, Boole's Technique in the "Laws of Thought"; Michael MacConaill, the Likeness of Correlated Relations; and L. E. J. Brouwer, the Effect of Intuitionism on the Classical Algebra of Logic. These papers will be published in a special issue of the *Proceedings* of the Academy.

Artificial Stimulation of Rain

IN the House of Commons on June 15, Mr. Geoffrey de Freitas asked the Under-Secretary for Air whether the physical sub-committee of the Meteorological Research Committee had yet considered the problem of weather modification; and what conclusions it reached. This matter had been raised earlier by Mr. de Freitas (see *Nature*, March 13, p. 474). Mr. George Ward, in a written reply, stated that the committee had recently considered this subject and come to the conclusion that there is no reliable evidence that rainfall has ever been artificially increased on an economically useful scale, and that there is no scientific basis for believing that any method yet proposed would be successful in achieving such a result. Since there is so much at stake, however, the committee considers that scientifically conducted research should be intensified, particularly into the large-scale diffusion of airborne particles, the analyses of natural nuclei concentrations and the design of the large-scale field trials which would be necessary to test the effectiveness of the proposed methods of operation. The Meteorological Office is putting in hand the studies recommended by the sub-committee.

Research and the Future of the World

IN an address entitled "Today's Research and Tomorrow's World" to guests of the board of directors of the Stanford Research Institute at Los Angeles on January 20 (pp. 16. Washington, D.C.: Carnegie Institution of Washington, 1954), Dr. Vannevar Bush, reviewing the possibilities of atomic warfare which confront us, said that whatever the future has in store, whether an atomic war, a long stalemate or a gradual transition to a more salutary position, for the present we should, by creating strength in the free world, seek to maintain peace and postpone a fully developed impasse. One phase of this, he said, involves building an adequate defence system for the North American Continent, which at present is nearly wide open to aerial attack. This lack of balance is due chiefly to two reasons: first, it has only fairly recently, through technical advances, been possible to ensure a reasonable and economic degree of protection, sufficient to raise doubt in the mind of an enemy as to the success of a single surprise attack; secondly, the national military planning organization is short of the sound integrated system essential for national safety. In Dr. Bush's opinion, the United States could have a defensive system which is worth while, without unduly burdening its economy or unwise sacrifice of any other element in its military preparedness, and should insist on having it and the improved military planning. After referring also to the need to make its system of democracy work and maintain vigorously some of its ideals of freedom, Dr. Bush turned to some of the trends in research and development which offer new hope. The bloc-

soming of the biological sciences and their application in agriculture, the opening-up of arid areas by solar power, new methods of sterilizing and packaging, etc., offer prospects of a breathing space from the pressure of increase in population. Chemical control of mental disease might be a powerful weapon in the war against man's ills. Progress is also being made in the handling of giant molecules, which require a new type of chemical thinking. There have been great strides in the development of machines for supplementing and substituting human thought; but this process needs to go much further before we can cope with the complexities of the coming world. Dr. Bush referred specifically to problems of communication in which new techniques of electronic selection, photomicrography and facsimile transmission would replace the conventional library. There is, however, a reason for the search for knowledge which is inherent in the nature of man. His search for understanding is prompted not simply by his immediate needs for food and shelter, but also by his inherent urge to know. Science should be pursued, Dr. Bush concluded, in response to the urge which lies deep in all of us to press on towards greater understanding.

The National Research Development Corporation

In the debates on the Development of Inventions Bill and again in the recent report on industry and science issued by the Manchester Joint Research Council, opinion was expressed that the work of the National Research Development Corporation is not sufficiently well known in industry. The *NRDC Bulletin*, of which the first number appeared in April (No. 1; pp. 20; 1954), is an attempt to remedy this position by informing industry of the inventions which can be made available by the Corporation in addition to, or in place of, the existing routine circulation procedure. It is hoped that in time the *Bulletin*, which will be published quarterly, will become the Corporation's chief vehicle for informing industry of such inventions. Each issue will include short notes of the inventions recently available, as well as on other inventions which have been the Corporation's property for some time and which it is considered should receive wider publicity. It is also proposed that each issue shall contain at least one article about other aspects of the Corporation's activities. Besides the descriptions of selected inventions, the present issue includes a note on the granting of licences and a list of the Corporation's patent holdings, arranged in the eight groups: electronics; electrical engineering; mechanical engineering; civil engineering; aero and auto engineering; scientific instruments; chemistry and plastics; miscellaneous and domestic. The *Bulletin* is obtainable from the Exploitation Officer, NRDC, 1 Tilney Street, London, W.1.

Simultaneous Translation at a Scientific Meeting

On May 11, at a meeting held at the Institut Pasteur in Paris, Prof. J. H. Quastel, professor of biochemistry in McGill University, Montreal, delivered by invitation an address on "Soil Metabolism". The occasion was noteworthy for the use of a system of simultaneous translation, analogous to that used at meetings of the United Nations and similar bodies. Thus Prof. Quastel delivered his lecture in English, and the difficult task of simultaneous translation was carried out by Dr. P. R. Lépine, of the Institut Pasteur. Dr. Lépine had actually seen Prof. Quastel's

manuscript for a short time before the meeting; it was nevertheless a considerable achievement to be able to give a simultaneous translation of a scientific discourse in a way which the audience found to be completely successful. At the conclusion of the lecture, Prof. J. Trefouël, director of the Institut Pasteur, thanked Prof. Quastel and, as is customary when distinguished visitors address the Institut Pasteur, presented to him a silver medal, which bears a figure of Pasteur by the sculptor Roty.

Recognition of Intoxication

In a study of the chemical diagnosis of alcoholic intoxication (*S. Afr. J. Med. Sci.*, 18, 141; 1953), J. J. Prag has attempted to correlate the usual clinical criteria of drunkenness with blood-alcohol levels. The tests were made on a hundred motor-car drivers, charged with driving under the influence of alcohol, and on a group of volunteers. One of his conclusions is that with blood-alcohol levels below 0.05 per cent (gm./per 100 ml.) nobody is intoxicated in the medico-legal sense, while with a level above 0.15 per cent most people (more than 90 per cent) are definitely intoxicated. The weakness of the chemical diagnosis lies in the blood-alcohol range between 0.05 and 0.15 per cent, where individual variations in symptoms are very great. The average ratio of blood-level to urine-level of alcohol was found to be 1:1.31, though the blood-level reflects more directly the alcohol concentration affecting the nervous system. With a given amount of alcohol, the greatest degree of intoxication is reached well before the blood-level reaches its maximum. If sugar is taken with alcohol, the symptoms are more severe but pass off more quickly, apparently owing to more rapid absorption and removal of alcohol. The results of this work are, on the whole, in harmony with the recent report entitled "The Recognition of Intoxication" by the Committee of the British Medical Association (1954) under the chairmanship of Prof. E. J. Wayne. Both Prag and the Committee stress that symptoms of impaired judgment may appear after drinking small amounts of alcohol and long before the stage of definite intoxication is reached. Diagnosis of drunkenness should not depend solely on results of laboratory tests, but on clinical findings, combined, if possible, with laboratory tests.

Tobacco Curing Studies

BIOCHEMICAL and physical changes which take place in tobacco leaves during fine-curing are described in some detail by H. O. Askew *et al.* (*N.Z. J. Sci. and Tech.*, B, 35, 4, 344; 1954). Data for changes in weight and moisture content of tobacco leaves during fine-curing show that the rate of loss of water is governed by the temperature and humidity conditions in the kiln. In the early stages of curing, 93-95 per cent of the loss of weight of the leaf is due to loss of water. During the colouring and fixing stages, rapid hydrolysis of starch to sugars, mainly glucose and fructose, and hydrolysis of protein-nitrogen to simpler compounds, take place. For the first 50 hr. of curing, the average rates of hydrolysis were: starch 0.35 per cent in two experiments; and protein-nitrogen 0.5 per cent and 0.7 per cent, respectively. Increase in reducing-sugars content was proportional to the amounts of protein and of starch hydrolysed. Loss of dry-matter can be nearly completely accounted for by requirements of water, by the products of hydrolysis, and by difference between over-all loss of starch and that required for

formation of soluble sugars. Internal transformations involving no losses of dry-matter may also have occurred. Variation in the contents of total non-volatile ether-soluble acids and malic acid was appreciable, but for oxalic and citric acids it was relatively small. Nicotine content did not vary during curing. No certain losses of total nitrogen were found. The pH value of the leaf did not vary. Neither soluble phosphate, soluble sulphur and protein-sulphur contents, nor soluble calcium content, varied during curing of the leaf.

Curing of Sheepskins In the Sudan

A LARGE-SCALE experiment on the curing of sheepskins has been carried out in the Sudan. The straight drying of sheepskins was compared with dry salting in the hot and in the cold seasons; drying in the sun was compared with shade-drying, and rope-drying with framing. At each season nine batches of fifty skins each were treated, the skins later being dressed in England as white suede. Straight drying gave almost consistently the best leather and cold season 'cure' was better than hot. Damage was found to be present in the raw skins although it could only be recognized microscopically. In its milder form it caused the grain to be rubbed off during processing or caused holes to appear in the skins; extreme damage led to complete disintegration and the skins dropped to pieces. It is suggested that an immediate improvement in the quality of 'curing' in the Sudan might be achieved by abandoning dry-salting, and by straight-drying the skins without delay, avoiding excessive heat in the direct sun (*Colonial Plant and Animal Products*, 3, No. 4: 1952-53).

Formation of Asparagine In Lupin Seedlings

THE formation of asparagine in etiolated seedlings of *Lupinus albus* has been considered in some detail on the basis of analytical and experimental investigations by A. N. Meiss (*Bull. Connecticut Agric. Exp. Sta.*, No. 553, 1; 1952). In this bulletin recent work on the biochemistry of asparagine formation is reviewed, while in the experimental section the germination and growth of etiolated seedlings are described and comprehensive analyses of these materials submitted, reference being made to the nitrogen fractions, lipids, soluble and insoluble carbohydrates, organic acids, moisture and ash. In the discussion of the experimental data, the relation of asparagine accumulation and growth, the sources of the asparagine nitrogen and carbohydrate, and the role of the organic acids and mineral nutrients are considered. The principal conclusion which is drawn is that the large accumulation of asparagine in etiolated seedlings of *Lupinus* is a consequence of a normal, but obligatory, utilization of seed protein as a respiratory substrate. The asparagine which arises by secondary synthesis—in the *Lupinus* seedlings it is about 90 per cent of the total formed—is considered to be a product of protein respiration, and as such is not metabolized further until acute starvation conditions prevail. Other observations and results which are associated with this conclusion are set out and discussed in detail.

Growth of Excised Roots

In one of a series of studies of the growth of excised roots in controlled aseptic culture, J. C. Skinner and H. E. Street have investigated the cultural requirements of a number of strains of

Sensio vulgaris (groundsel), which also have been, and are being, studied genetically (*New Phyt.*, 53, 1, 44; 1954). Earlier work, in which it was found that excised roots of strains within a species may show clearly defined differences in their capacity for 'essential metabolite' synthesis, is reviewed. The underlying point of view in these new physiological-genetical studies is that more detailed examination of the differences in the growth requirements of different strains should enable a comparative physiology of excised root systems to be constructed. The differences observed in the growth responses of cultured excised roots of tomato strains to added B vitamins suggests that this technique may be used to advantage in the study of the genetical control of synthetic processes in flowering plants. Seeds of a number of geographical strains of *Sensio vulgaris* were available and excised roots have now been successfully cultured. The present paper gives details of a technique for the establishment and maintenance of excised root clones and describes the growth responses of one clone to a range of nutritive treatments. Subsequent work has involved comparison of the growth in selected culture media of the roots of a number of geographical strains and of hybrids between them, and study of the segregation of excised root characters in the *F*₂ generations of these crosses.

Flake-Tool Cultures In South Africa

AN article by Prof. T. F. Dreyer, entitled "The Origin and Chronology of the Fauresmith Culture" (*Res. Nat. Museum, Bloemfontein*, 1, Part 3; 1953), makes an interesting suggestion as to the origin of the flake-tool cultures which appear with some suddenness at the end of Fauresmith times. The current view of many prehistorians in South Africa is that the Middle Stone Age complex (flake-tool industries) is directly derived from the Stellenbosch (core-tool industries), the Fauresmith being the latest of the Stellenbosch series. It is not easy to explain why this change should have taken place at the time it did and why the coupe de poing which had persisted for perhaps scores of thousands of years throughout many changes of climate and conditions should have so rapidly disappeared and been replaced by others so completely different, unless influences from outside had operated. In Europe and northern Asia, where a similar phenomenon occurs, it can be shown from distribution maps that the flake-tool making cultures existed farther to the east contemporarily with the core-tool making people, and replaced them in western Europe towards the end of Würm I times. Prof. Dreyer suggests a somewhat similar solution for the problem in South Africa in that he believes the Florisbad (flake-tool) culture to be older in time than has been hitherto allowed, and that it was the influence of this culture on the Fauresmith that led to the development of the Middle Stone Age; and that it was fertilization by the Florisbad culture that gave rise to the profound changes which took place towards the end of the Fauresmith period. Certainly the natures of the two cultures were entirely different. The coupe de poing folk were conservative and uniform in their implement evolution—the development of the industries throughout millennia is the same whether in South Africa, East Africa or Western Europe (= the Chellean-Acheulean culture). The flake-tool makers were quite different, always experimenting and producing changes and new types of tools. It is difficult to see how the one

culture could have evolved into the other without some such explanation as Prof. Dreyer proposes. But the ultimate origin of the flake-tool folk, whether one is considering those in northern latitudes or their cousins in South Africa, still remains a mystery.

Syntheses of a Pituitary Hormone

THE synthesis of oxytocin, a principal hormone of the posterior pituitary, has been announced by Prof. V. du Vigneaud, professor of biochemistry, Cornell University Medical College, and his colleagues, C. Reeser, J. M. Swan, C. W. Roberts, P. G. Katsouyannis and S. Gordon (*J. Amer. Chem. Soc.*, 75, 4879; 1953). Oxytocin causes contractions of the uterus, and is also concerned with the 'let-down' of milk from the mammary gland. Previous work had shown that natural oxytocin on hydrolysis yields leucine, isoleucine, tyrosine, proline, glutamic acid, aspartic acid, glycine and cystine, and three molecules of ammonia. Based on these results, a synthetic product was obtained by a method described and had the biological properties of natural oxytocin. The authors remark that, if the identity of the synthetic material with oxytocin is confirmed, this will be the first synthesis of a polypeptide hormone.

Japanese Journal of Tuberculosis

MUCH activity is evident in Japan in the field of tuberculosis, and in no less than six universities there are institutes devoted to research in this disease, or in which such study figures prominently. These institutes have now joined in sponsoring a quarterly journal, the *Japanese Journal of Tuberculosis* (pp. 98; November 1953; from the Institute of Infectious Diseases, Shiba-Shirokane-Daimachi, Minato-Ku, Tokyo), under the editorship of Y. Takeda and with a representative editorial board. The first number presents mainly laboratory studies, but also some articles on clinical and epidemiological aspects. It is well produced and is in English. This lusty newcomer to national specialist literature invites comparison with the several British tuberculosis journals, which are showing little success in attracting scientific contributions—particularly those of a laboratory nature—away from their very scattered distribution in other publications.

Photoelectric Scanners for use In Paper Electrophoresis

THERE are numerous descriptions in the literature of instruments for measuring the intensity of the dyed serum protein bands after electrophoresis on paper, which utilize a photoelectric cell for measuring the light transmitted or reflected from a suitable source. By plotting extinctions at given distances along the paper strips, a graph is obtained which provides a quantitative evaluation of the proteins present. Such instruments are now produced commercially. The firm of Evans Electroscelenium, Ltd. (Harlow, Essex), provides, in addition to the scanning apparatus, a power unit and specially designed bath for carrying out the initial protein separation. As the scanning apparatus employs transmitted light, the dyed paper strip requires to be wetted with a suitable liquid to render it translucent. A frame carries the translucent strip between two glass plates and has a platform for holding a sheet of graph paper. The whole is moved across the light source, and extinctions read off from a microammeter and plotted on the graph paper. Joyce, Loeb and Co.,

Ltd. (Vine Lane, Newcastle upon Tyne 1), produces a somewhat more elaborate scanning apparatus (Model 2SR), which incorporates a double-beam amplifier principle and measures reflected light, obviating the need for rendering the paper translucent. It also has a framework for moving the paper across the light source and a platform for holding graph paper; but instead of reading off the extinctions, their values are directly plotted on the graph paper by a pen attached to a slider which is adjusted until the milliammeter reads zero. A feature of both instruments is that readings may be carried out quickly and easily. They are thus suitable for routine clinical investigations. The instruments are also adaptable for measuring the intensity of coloured spots on paper chromatograms.

Determination of the Resolving Power of Photographic Lenses

CIRCULAR 533 of the National Bureau of Standards, Washington, D.C., entitled "Method for Determining the Resolving Power of Photographic Lenses" (pp. iv + 27 + 2 charts. Washington, D.C.: Government Printing Office, 1953; 1 dollar), replaces Circular 428 (1941), and provides the photographer with two sets of improved charts by which the resolving power of a photographic lens may be numerically measured with respect to a definite scale of values. It gives a detailed description of the procedure and technique to be followed in order that comparable values may be obtained by different observers in widely separated laboratories. The average amateur photographer can use the simple objective method described with equipment normally available. One set of charts consists of six high-contrast charts, printed in black ink on a white background, and the other set contains six low-contrast charts, printed in grey ink on a grey background. The range of the charts is 12–80 lines/mm. in contrast with 3.5–56 lines/mm. of the charts in Circular 428. Additional applications to the testing of goggle lenses for definition and prismatic power and of telescopes and binoculars for definition are also discussed in Circular 533.

Hydraulic Research in the United States

INFORMATION compiled from various hydraulic and hydrologic laboratories, and from reports of research projects in private, State or Federal institutions in the United States and in five institutions in Canada, is contained in Miscellaneous Publication 208 of the National Bureau of Standards, entitled "Hydraulic Research in the United States" (pp. xii + 204; edited by Helen K. Middleton and Sonya W. Matchett. Washington, D.C.: Government Printing Office, 1953; 1.25 dollars). The projects are numbered chronologically, and the number once assigned is repeated for identification purposes until the project is completed. Numbers above 1544 refer to projects reported for the first time; lower numbers to projects reported earlier in the previous editions (Misc. Publication 201, 1951; Misc. Publication 205, 1952). The information listed gives the title of the project; for whom conducted; the name of the person to whom correspondence should be addressed; the nature of the project (whether experimental, theoretical, etc.); and a brief description of the work, the results so far obtained and any published reports. There is also a comprehensive subject index. In the brief foreword by Dr. A. V. Astin, director of the National Bureau of Standards, Washington,

D.C., it is mentioned that a similar bulletin, "Hydraulic Research", compiled and published by the International Association for Hydraulic Research, contains information on hydraulic research conducted outside the United States, and a companion bulletin, "Directory of Hydromechanics Research Projects in the United States Related to Naval Architecture and Marine Engineering", is prepared by the Hydromechanics Committee of the Society of Naval Architects and Marine Engineers.

Physicists In Britain during July

A list of those taking part in the Eighth General Assembly of the International Union of Pure and Applied Physics, to be held in the rooms of the Royal Society (Burlington House, London, W.1) during July 7-10, has been prepared and is obtainable on application to the assistant secretary of the Royal Society. The numbers of active participants from various countries are as follows: Great Britain, 14; United States, 9; Germany, 7; Canada, 6; France and Italy, 5 each; Spain and Japan, 3 each; Australia, Denmark, Netherlands and Switzerland, 2 each; Belgium, India, Israel and Sweden, 1 each. Since such a comparatively large number of leading foreign physicists will be in Great Britain for the Assembly, a number of other meetings have been arranged around about the same time (see *Nature*, January 30, p. 194), and it is expected that many of the foreign physicists will be attending one or other of these meetings.

Meeting of Nobel Prize-winners in Lindau

As in former years, a meeting of Nobel prize-winners will be held in Lindau, Lake Constance, during June 28-July 2. This year the speakers will discuss various aspects of medicine, which is the second time that this subject will be considered at one of these meetings, the first occasion being at the original meeting in 1951. Ten addresses will be given as follows: Prof. Gerhard Domagk (Wuppertal), Chemotherapie der Tumoren; Prof. Hans von Euler-Chelpin (Stockholm), Faktoren der Blutbildung; Prof. George de Hevesy (Stockholm), Eisenstoffwechsel; Prof. Corn. Heymans (Ghent), über Selbststeuerung des arteriellen Druckes und Hypertension; Dr. Paul Hermann Müller (Basle), Antibiotica, besonders ihre Anwendung im Pflanzenschutz; Prof. T. Reichstein (Basle), die wichtigsten Hormone der Nebennierenrinde; Prof. Frederick Soddy (Oxford), the Wider Aspects of the Discovery of Atomic Disintegration; Prof. George H. Whipple (Rochester, N.Y.), the Dynamic Equilibrium of Body Proteins, Hemoglobin, Plasma Proteins, Organ and Tissue Proteins; and Prof. Adolf Butenandt (Tübingen) and Prof. Otto Warburg (Berlin), whose topics are not yet decided. Also participating will be Prof. Otto Hahn (Göttingen) and Prof. Albert Schweitzer (Lambaréné-Gabon). The addresses will be of general interest to both medical practitioners and research workers, and opportunities will be provided for discussion. A comprehensive programme of excursions has also been arranged. Further information can be obtained from the Sekretariat der Tagungen für Nobelpreisträger, Lindau-Bodensee, Postfach 11.

Royal Commission for the Exhibition of 1851: Awards for 1954

THE Royal Commission for the Exhibition of 1851 has awarded senior studentships for 1954 (value £600

a year for two years) to the following for research as indicated: Miss A. I. Bailey (Witwatersrand), physics at the University of Cambridge; Dr. G. A. Horridge (Cambridge), invertebrate physiology at the University of Cambridge; R. Hicks (Wales), civil engineering at University College, Cardiff; and A. D. Walker (Bristol), vertebrate palaeontology at King's College, Newcastle upon Tyne (University of Durham). The Commission has also awarded the following overseas scholarships for 1954 (value £450-£500 for two years). *Canada*: M. J. Fraser (Dalhousie), colloid chemistry at the University of Cambridge; M. Onyszchuk (McGill and Western Ontario), inorganic chemistry at the University of Cambridge; and J. A. Kuehner (Bishops and Queen's University, Kingston), nuclear physics at the University of Liverpool. *Australia*: P. J. Stephenson (Queensland), geology at the Imperial College of Science and Technology, London; and F. W. Eastwood (Sydney), organic chemistry at the University of Oxford. *New Zealand*: G. N. Maloolm (New Zealand), physical chemistry at the University of Manchester. *South Africa*: Dr. S. Papert (Witwatersrand), mathematics at the University of Cambridge. *Republic of Ireland*: Dr. M. F. Maguire (Ireland and Aberdeen), biochemistry at the University of Cambridge. *Republic of India*: K. Aghoramurthy (Madras and Delhi), organic chemistry at the University of Oxford; and S. Chandra-sekhar (Nagpur), physics at the University of Cambridge.

National Research Council of Canada Fellowships for Medical Research

EACH year the National Research Council of Canada has awarded the following medical fellowships, totalling 76,900 dollars plus travelling allowances, for research at the institutions indicated. *Senior Medical Research Fellowships*: Dr. W. G. B. Casselman, Banting and Best Department of Medical Research, University of Toronto; Dr. C. N. Crowson, Department of Pathology, Queen's University, Kingston, Ontario; Dr. P. C. Fitz-James, Department of Bacteriology and Immunology, University of Western Ontario; Dr. R. W. Gunton, Department of Medicine, University of Toronto, and at the Toronto General Hospital; Dr. F. C. Heagy, biochemistry and bacteriology at the University of Western Ontario; Dr. H. Kalant, pathological chemistry at the University of Toronto; Dr. J. T. Nichol, biophysics at the University of Western Ontario; Dr. J. W. Pearce, physiology at the University of Western Ontario; *Graduate Medical Research Fellow*: Dr. D. E. Bergsagel, blood coagulation at the University of Oxford; Dr. R. W. Cornett, cardiovascular physiology at Queen's University, Kingston, Ontario; Dr. T. E. Cuddy, cardiovascular physiology at the University of Manitoba; Dr. A. Davignon, physiology and biochemistry at Hotel Dieu Hospital, Montreal; Dr. Florence M. Hill, pathology at the University of Toronto; Dr. N. Kalant, endocrinology at the New England Centre Hospital, Boston, Massachusetts; Dr. S. J. Klebanoff, pathological chemistry at the University of Toronto; Dr. Dorothy Ley, iron metabolism in neoplastic disease at Toronto Western Hospital; Dr. A. Malkin, biochemistry at McGill University; Dr. J. C. Nixon, biochemistry at the University of Toronto; Dr. J. E. Nixon, physiological and pharmacological problems related to anaesthesiology at the University of British Columbia; Dr. P. Pollock, cardiology at Mt. Sinai Hospital,

New York City; Dr. Ingeborg C. Radde, endocrinology at the University of Toronto; Dr. R. F. Scott, pathology at the London Postgraduate Medical School, Hammersmith Hospital, London, England; Dr. Joan M. Vale, endocrinology at the University of Toronto.

University of Glasgow

AMONG those on whom the honorary degree LL.D. was conferred on Commemoration Day at the University of Glasgow, there were two members of the 1914 Shackleton Polar Expedition: Prof. Alexander Stevens, sometime professor of geography in the University of Glasgow, and J. M. Wordie, master of St. John's College, Cambridge, and director of the Scott Polar Research Institute. Other men of science were: Prof. Boris Ephrussi, professor of genetics in the University of Paris, whose ideas and early experiments have strongly influenced the present developments in biochemical genetics; and Sir Edward Salisbury, director of the Royal Botanic Gardens, Kew. Sir Arthur Trueman, sometime professor of geology in the University of Glasgow, and lately chairman of the University Grants Committee, was given the degree *in absentia*.

University of Birmingham

THE title of reader in analytical chemistry in the University of Birmingham has been conferred on Dr. R. Belcher, senior lecturer in analytical chemistry, and the title of university research fellow on the following: Prof. D. L. Anderson, associate professor of physics at Oberlin College, Ohio, who will be working in the Department of Physics for a year; and W. D. Seymour, during the tenure of his present appointment in the Department of Engineering Production. The following appointments have been made in the University: Dr. J. D. Eshelby, lecturer in physical metallurgy; Dr. A. B. Foster, Imperial Chemical Industries, Ltd., Fellow in the Department of Chemistry; and F. Edmondson, Leverhulme Fellow in the Department of Engineering Production.

University of Leeds

THE following appointments have been made in the University of Leeds: J. B. Butler, senior agricultural economist in the Department of Agriculture; Prof. B. E. Douglas and Prof. H. Taube (Chicago), Brotherton research lecturers in physical chemistry; E. W. Bennett, lecturer in the Department of Civil Engineering. The Department of Bacteriology has received a gift of £700 from Newton Chambers and Co., Ltd., for research.

The Night Sky in July

FULL moon occurs on July 16d. 00h. 29m., U.T., and new moon on July 29d. 22h. 20m. The following conjunctions with the moon take place: July 3d. 15h., Venus 5° N.; July 9d. 18h., Saturn 8° N.; July 14d. 00h., Mars 8° S.; July 28d. 08h., Mercury 2° S., and at the same time Jupiter 0° S. In addition to these conjunctions with the moon, Venus is in conjunction with Regulus on July 12d. 08h., Venus 1.1° N., and Mercury is in conjunction with Jupiter on July 28d. 00h., Mercury 1.9° S. Mercury, in inferior conjunction on July 6, is too close to the sun to be seen until near the end of the month; on July 31 it rises at 2h. 50m., nearly an hour before sunrise. Venus is an evening star, its times of setting being 22h. 20m., 22h. 50m. and 21h. 15m. at the beginning, middle and end of the month, respec-

tively. Its stellar magnitude varies between -3.5 and -3.6, and the visible portion of its illuminated disk between 0.76 and 0.66. Mars is visible throughout the night, setting in the early morning hours at 2h. 40m., 1h. 20m. and 0h. 15m. on July 1, 15 and 31, respectively. Its fairly close approach to the moon on July 14 has been already noticed, but observation of the planet will not be then very easy as the moon is only two days from full. During the early portion of July Jupiter is too close to the sun to be seen, but on July 15 it rises at 3h. and on July 31 at 2h. 25m. and is visible for a short time in the constellation Gemini. Saturn sets at 0h. 40m., 23h. 40m. and 22h. 40m. on July 1, 15 and 31, respectively, and is visible during the early morning hours in the constellation Virgo. Only one occultation of stars brighter than magnitude 6 takes place in July: 18 Aquar. reappears on July 17d. 22h. 45.8m., the observation being made at Greenwich. The earth reaches aphelion on July 3.

A partial eclipse of the moon takes place during July 15-16 and is visible at Greenwich. The circumstances of the eclipse are as follows:

Moon enters penumbra	July 15d. 21h. 47.7m.
Moon enters umbra	15 23 00.4
Middle of the eclipse	16 00 20.3
Moon leaves umbra	16 01 31.3
Moon leaves penumbra	16 02 52.9

Magnitude of eclipse is 0.411, the diameter of the moon being 1.

Announcements

THE 1954 award of the Commemorative Medal of Prince Albert I of Monaco (Prix Manley-Bendall) has been made to Captain de Corvette G. Houot and Engineer Officer P. Willm, of the French Navy, for their great achievement in descending to a depth of just over 2½ miles off Dakar in the naval bathyscaphe *F.N.R.S.-3*. The award was announced at the meeting of the Executive Committee of the Institut Océanographique held in June at Paris, and the donor of the Medal is generously having it struck in duplicate so that each recipient can possess it.

A Folk Gallery in the Abbey House Museum, Kirkstall, will be opened by Dr. F. Sherwood Taylor, director of the Science Museum, London, on July 2, at 11 a.m. The gallery is in the form of a small street called "Abbey Fold".

THE British Institution of Radio Engineers will hold its annual convention at Christ Church, Oxford, during July 8-12; the theme this year will be the application of electronics to industry. Representatives from many branches of industry as well as from the Armed Services, universities and technical colleges will be present. Further information can be obtained from the Institution at 9 Bedford Square, London, W.C.1.

A SYMPOSIUM on "The Comparative Endocrinology of Vertebrates" will be held in the Department of Zoology, University of Liverpool, during July 12-16. The symposium will be in two parts—the comparative physiology of reproduction, and the hormonal control of water and salt-electrolyte metabolism in vertebrates—under the respective chairmanship of Prof. S. Zuckerman and Dr. S. J. Folley. The proceedings of the symposium will be published as a memoir of the Society for Endocrinology. Accommodation is available at the University. All communications should be directed to the organizer, Dr. I. Chester Jones, Department of Zoology, University of Liverpool.

WORLD POPULATION AND RESOURCES

DURING May 5-6 the Executive of the International Geographical Union met in London, and the opportunity was taken to ask three of the vice-presidents to take part in a symposium on world population, under the chairmanship of the Union's president, Prof. L. Dudley Stamp, at the Society for Visiting Scientists.

The discussion was opened by Prof. George B. Cressey (Syracuse University, New York), the immediate past-president of the Union, who outlined briefly the world position which he had elaborated in his presidential address at the Washington conference of 1952¹. He used the now generally accepted figures of 2,500 million for the present world population, with a net increase of not less than 25 million per annum. The reality of the situation was vividly brought home by the comment that, by the end of the two hours of discussion, there would be another six thousand mouths to be fed and also another six thousand pairs of hands potentially available for work. Prof. Cressey said that he has been impressed by the extensive abandonment of soil-eroded land over such diverse regions as the United States and China where he has worked and at the same time by the poverty of tropical soils, and he takes the view that the expansion of lands under cultivation will do little more than balance the loss due to erosion. He looks, therefore, for expansion of food output from improved yields of lands already under cultivation. Turning to the position in the United States, where farming efficiency is commonly equated with output per man-hour and not with output per unit area, there is little doubt that agricultural output could be doubled merely by the full application of known techniques. In fact, the doubling of the production between 1900 and 1950 has been achieved by technological advances without any increase in man-power: the spectacular changes in yield which have resulted from the introduction of hybrid maize are indications of possibilities with other crops. The main problem for the future would seem to be an embarrassing surplus, and little likelihood that the prairie monoculturalist will be asked to give up his winter holiday in California in order to secure the greater output from the adoption of mixed farming.

Prof. George Kuriyan (Madras) gave a brief but vivid word picture of the position in the Indian sub-continent, contrasting in almost every conceivable way with the United States. He pointed out that the Union of India had a population of 357 million in 1951 (approximately a seventh of the world's total), compared with 235.5 million over the same area in 1901. During the past three decades (that is, after the great influenza epidemic of 1918-19) the absolute increase in numbers over the whole Indo-Pakistan sub-continent has been approximately 50 million per decade. The British Indian Government, Prof. Kuriyan said, handed on a stable administration after a long period of peace and absence of famine. Improvements in medicine, both preventive and curative, have combined to produce a diminishing death-rate of about 2 per cent per annum against a birth-rate of more than 3.

To compensate this growth, there has been no corresponding increase in the resources, which, as in the past, have remained essentially agricultural. From the beginning of this century, there has been a race between population and resources; but since 1921 population has outstripped resources so significantly that in 1951 the total *per capita* production, taking note of all agricultural output, food and cash crops combined, was approximately 450 lb., while the corresponding figure for 1901 was 600 lb. Furthermore, the pressure upon land has increased so considerably that many parts of the country suffer from over-population, tracts with good agricultural resources having as much as 3,000-4,000 persons per square mile. This, in its wake, has led to the emergence of a class of landless labourers whose total numbers are estimated at 45 millions, a group of people who constitute a vulnerable section in the hands of political propagandists.

The real remedies appear to be, first, to increase the average yield of crops, which to-day is appallingly low; second, to enhance the area under cultivation by improvements in irrigation; third, to find employment for the population in avenues other than agriculture; and fourth, to have a conscious and deliberate check on population growth. The last is certainly the most important; but it is doubtful if it is easily practicable in a country like India, where the standards of education are so low and where religious feelings of the bulk of the population have always looked upon a son as a blessing from Heaven and the more sons the greater the security.

Prof. Hilgard O'Reilly Sternberg (Catholic University of Rio) presented a very different picture from Brazil. The extremely rapid increase in population, now more than 56 million, has been due to only a minor extent to immigration over the past century. Development and close settlement, for so long almost confined to a belt within 100-150 miles of the coast, is now taking place with staggering rapidity in many inland centres. New towns on the pioneer fringe within a few years are finding themselves by-passed as new pioneers move on. It is something like the westward expansion of the United States a century ago but with important differences. Social factors often play a greater part than either physical or economic: there is prestige attached to the ownership of large herds of cattle, and none to the raising of crops of wheat. Consequently, as Prof. Sternberg showed by a series of detailed maps based on the 1950 census, expansion of wheat cultivation coincides mainly with areas of German settlement and not necessarily with the most favoured tracts of land.

The chairman suggested that the three speakers illustrated in a remarkable way that there are at least four levels in the population-food problem. One is the somewhat academic global view; the second the national where, for example, the situations in the United States and India are in marked contrast; in the third place, Brazil illustrates the difference between regions, as well as the fourth stage, which is almost a pin-point relationship between an individual farm or settlement and its productive capacity. While the papers showed the

over-riding importance of the physical factors such as climate and soil, economic factors such as farm prices playing an obvious part, the imponderable social factors illustrated by religion and prestige are extraordinarily powerful and persistent.

In the discussion which followed, speakers raised such questions as the increased use of fertilizers and the 'cultivation of the sea'. Three other vice-presidents of the Union were present—Prof. Max Sorre (Paris), Prof. Orlando Ribiero (Lisbon) and Prof. Hans Boesch (Zurich). Prof. Boesch thought the papers emphasized the peculiarly difficult position of the older and more populous countries of Europe relying on their exports to purchase essential food-stuffs from overseas. It is clear, he said, that the great primary producers are not only using more and more of their home production, but are also regarding it as a matter of national prestige to develop their own manufactures.

ACOUSTICS OF ORTHOPTERA

A SYMPOSIUM on orthopteran acoustics was held at Jouy-en-Josas, near Paris, during April 5-8 under the auspices of the French Ministry of Agriculture (Institut National de la Recherche Agronomique) and the able management of R.-G. Busnel, director of the Laboratoire de Physiologie Acoustique. It was intended both to be international and to be a meeting-ground for the scientific interests—physical, systematic, physiological, ethological and ecological—which touch each other in this field. In the event, although it is to be regretted that Italy, the Iron Curtain countries and the Americas were unrepresented, it provided the first opportunity since the Second World War for discussion of the subject between French, German and British scientific workers, a discussion much facilitated by comprehensive pre-circulation of individual contributions in two or three of their languages.

There has been little recent work on the physiology of hearing in insects; and apart from a useful survey of this part of the field by H. Autrum (Würzburg), the conference divided its time almost equally between papers on three aspects of the subject: the technique of recording and reproducing the sounds produced by insects; the analysis, oscillographic and spectral, of such sounds with attempts to relate the results, on one hand, to the structure and movements of the insect and, on the other, to the confusing and ambiguous terminology already in use; and the function of such sounds in communication between insects of the same species. Since the complete proceedings will be published shortly in French, it would be unprofitable, even if it were practicable, to abstract each contribution and each discussion here. It seems better to give what to one observer were the salient features of the conference as a whole.

The saltatorial Orthoptera, though not the only insects in which communication by sound has been established, are the best known and have shared with the cicadas the ability to interest and exasperate the human hearer for millennia. But it is only very recently that technical equipment has become available for recording, analysing and synthesizing their songs and so making possible an experimental investigation of their meaning. The pioneer observations of Regen and Faber had already established

that different meanings inhered in different varieties of songs; but they had also shown that in certain circumstances a typical response could be obtained to the crudest of imitations while, in others, the insect was not seduced by what appeared to be a perfect copy. This contrast was sharply pointed by two contributions to the symposium. W. Loher (Paris) showed, in an attractive colour-film, how by an imitation made with his own mouth of the 'ordinary song' of *Chorthippus brunneus* (*ci-devant bicolor*), he could attract females of the species on to his person and even on occasion on to his lips. On the other hand, M. and Mme. Busnel described how they had completely failed to obtain a response from the females of *Oecanthus pellucens* by playing back a high-quality record of the song of the male until, with the introduction of a new type of transducer, the ionophone, they began to get positive results. The ionophone, described and demonstrated to the symposium by its inventor, M. S. Klein (Paris), is clearly a technical advance of the first magnitude. It is a completely aperiodic loud-speaker with a flat response up to more than 100 kc/s., and it has a large undistorted power output from what is virtually a point source. It is nevertheless very remarkable that it should be necessary to employ so perfect an instrument in order to make a passable copy of the song of *Oecanthus*, for analysis has confirmed the aural impression that this song is comparatively 'pure', with a fairly simple oscillogram and a relatively narrow spectrum. It is evident that there is still much to be learnt about how the gryllids and tettigoniids detect a spurious copy; and it by no means follows that because some acridiids respond by a tentative approach to an indifferent imitation of the song of their own species, they are unable to distinguish it from the real thing. It is inevitable that comparisons should be made with the experiments of Tinbergen, Lack, Hartley and others, who have shown that a stereotyped reaction can often be elicited from vertebrates by 'models' which correspond only in one or two essential features with the prototype which normally evokes the reaction. Thus small birds which customarily mob tawny owls will mob any dark mottled object of approximately the right size; but they ignore a living barn-owl which is paler, though in other respects it seems to us a much better 'model' of a tawny owl. The determination of what features of the structure of insect songs are 'essential' in this sense to their communicative function is a task for the future, though the investigation is now technically possible. It was interesting and suggestive to find that a comparison of the oscillograms of the 'ordinary song' of *Ch. brunneus* and of Herr Loher's oral imitation disclosed a similarity in structure which was obvious neither to the untutored human ear nor to the spectral analyser.

The majority of vocal saltatoria produce their songs by one or other of two methods which we are accustomed to regard as standard for the group; but D. K. McE. Kevan (Nottingham) gave a substantial list of species employing unorthodox stridulatory devices which he described and which could only be regarded as the result of independent evolution. Unfortunately, little is known of the degree of development of the auditory (tympanal) organs in the heterodox species, or of the importance of stridulation in their life-history; but their existence (many of them are exotic) is a warning not to generalize too widely from the relatively poor orthopteran fauna of Western Europe. B. P. Uvarov

(London) emphasized this danger in pointing out that tympanal organs (ears) are well developed in many dumb acridiids, and that, when the Australian groups are taken into the account, their presence appears to be correlated more closely with the power of flight than with the ability to stridulate. No plausible explanation of this curious paradox has been suggested.

Papers dealing with the sound-field of various types of saltatoria and its relation to their habitat were read by R.-G. Busnel and by P. T. Haskell (London). It is possible to make guesses at the range within which stridulation is an effective means of communication and to account plausibly for some of the characteristic differences of the stridulation patterns of acridiids and tettigoniids in terms of their different habitats, the former insects being relatively densely distributed at ground-level while the latter are scattered in three dimensions. Nevertheless, both these papers made clear the need for better determinations of the auditory threshold in a larger number of species than have yet been attempted. Moreover, as Autrum emphasized in his introductory survey, the division of the auditory function between tympanal organs, sub-genual organs and cerci is a complication of which the consequences are not understood and have scarcely begun to be investigated. One can only agree with the observations of Prof. P. P. Grassé in the address with which he brought the conference to an end: "On ne peut dire que les études faites jusqu'ici sur les sons en tant que facteurs de la structure sociale ou du simple maintien du groupe soient satisfaisantes. . . . Un des mérites du présent Colloque sera d'avoir bien montré la nécessité d'établir les véritables nature et signification des réactions aux stimulations sonores". It must be admitted that this symposium represented seed-time rather than harvest; but it has performed a service of value in stimulating a reorientation of ideas and in indicating lines of research which are likely to be profitable, which are now technically possible, and which, moreover, are certainly relevant to a much wider field than its deliberately restricted agenda might suggest.

R. J. PUMPHREY

SMITHSONIAN INSTITUTION

REPORT FOR THE YEAR 1952-53

THE report of the Secretary of the Smithsonian Institution for the year ended June 30, 1953, to which are appended the usual reports on the United States National Museum, the Bureau of American Ethnology, the International Exchange Service, the National Zoological Park, the Astrophysical Observatory, the National Air Museum and the Canal Zone Biological Area*, points out that almost all the endowments were given for specific purposes and little of the income from the invested funds of the Institution is available for alteration or growth from year to year. Generally, the continuing activities of the Smithsonian Institution have financially remained static during the past twenty years or have even retrogressed. While the national collections in the care of the Smithsonian have increased by

130 per cent since 1934, the number of visitors to its five exhibition buildings has increased by 150 per cent, and the correspondence on scientific and other questions multiplied several times, the man-hours per week available at the Institution have decreased and the appropriation for functions other than staff is 11,000 dollars less than in 1933. Appropriations for the fiscal year 1954 will, however, permit first steps towards the overdue rehabilitation of its exhibitions and the renovation of some of its buildings, though funds for continued modernization and renovation will be urgently required in succeeding years as well as plans for new buildings.

At the end of 1952 the activities of the Institute of Social Anthropology were terminated, and anthropologists remaining on its staff were transferred to the Institute of Inter-American Affairs. Systematic researches of the anthropologists of the Bureau of American Ethnology included Dr. M. W. Stirling's archaeological work in Darien and on the islands of the Gulf of Panama, Dr. H. B. Collins's studies on the Eskimo and arctic anthropology, Dr. J. P. Harrington's studies of the Chumash Indians of the Santa Barbara Channel region, California, and those of Dr. P. Drucker of Meso-American archaeology. In the investigations of the River Basin Surveys carried out by the Bureau in co-operation with the National Park Service and the Bureau of Reclamation of the Department of the Interior, the Corps of Engineers of the Army Department and various State and local institutions, greater emphasis continued to be laid on excavation now that survey has largely caught up with the general programme. Of the 3,469 archaeological sites located and recorded by the survey parties, 852 have been recommended for excavation or limited testing. Already 172 preliminary appraisal reports have been distributed, and excavations made in 42 reservoir projects located in 17 States. Paleontological surveys have been made in 121 reservoir areas, and archaeological work has also been done in 88, while the remaining 33 will be visited by archaeological parties. Already 273 reservoir basins, including those where archaeological studies are still to be made, have been surveyed.

The collections of the National Museum increased by more than 1,607,000 specimens during the year, bringing the catalogue entries to nearly 35 million. Exploration and field-work during the year included C. O. Handley's observations and collections of mammals in the Kalahari desert region of north-eastern South West Africa, Dr. A. Wetmore's studies on the distribution of bird life in Panama, H. G. Deigman's ornithological work in Thailand, studies of coral-atoll ecology in Tahiti and on Raroia Atoll, and searches for invertebrate and vertebrate fossils by three parties at Adair, Oklahoma, in the Guadalupe Mountains of western Texas, in north, east and south Mexico and in south-central Wyoming. Accessions to the National Zoological Park numbered 810, bringing the net count of animals at the end of the year to 2,741, but there was a slight decrease in the number of visitors, who totalled about 3,231,000.

At the Astrophysical Observatory the manuscript of Vol. 7 of the *Annals of the Observatory*, covering its research during 1939-52, was completed and sent to press late in the year. A thorough study of the silver-disk pyroheliometer was completed in April 1953. Tape exposures to total sun and sky radiation continued at Montezuma, Chile, where a new modern seismometer is now being installed, and at Table Mountain, California, the permanence of the con-

* Smithsonian Institution. Report of the Secretary and the Financial Report of the Executive Committee of the Board of Regents, for the Year ended June 30, 1953. (Smithsonian Publication 4141.) Pp. x + 160 + 6 plates. (Washington, D.C.: Government Printing Office, 1953.)

stants of the Smithsonian double-tube, water-flow standard pyroheliometer and of the sub-standard silver disk pyroheliometer *S.I.5* has been confirmed. The researches of the Division of Radiation and Organisms continue to be concerned chiefly with the physiological and biochemical processes by which light regulates the growth of plants and the mechanisms of the action of the auxin type of growth hormone. Investigations of the effect of plant-growth regulators on the salt exchange of plants indicated that high salt-low carbohydrate plants lose salt more rapidly when treated with ammonium 2:4-dichlorophenoxyacetate, while low salt-high carbohydrate plants absorb salt less rapidly compared with untreated plants.

Of the seven hundred visitors to the Canal Zone Biological Area, fifty-seven were scientific workers who used the facilities of the station, considerably improved during the year, chiefly for biological and photographic studies. The 1,021,938 packages of government scientific and literary publications handled by the International Exchange Service during the year, an increase of 20,324 packages, included consignments to all countries except China, North Korea and Rumania. A grant of 6,000 dollars towards rising transport costs was received from the National Science Foundation. The Service now dispatches abroad sixty-three full and forty-two partial sets of United States official publications in exchange for the official publications of other Governments.

WOOL INDUSTRIES RESEARCH ASSOCIATION

REPORT FOR THE YEAR 1953-54

THE report of the Director of Research of the Wool Industries Research Association for 1953-54* expresses the view that the statutory levy for research, which has now been in operation for two years, has both increased the interest of members and also enabled the Wool Textile Research Council to clarify the relation of research at the universities and technical colleges to that of the Association. The pilot-scale scouring plant was completed towards the end of the year and has given results well up to commercial standard. Data have been obtained on the possibility of alkali damage to wool during commercial scouring. A prototype of the automatic controller for the woollen card designed in the Association's laboratories some years ago is undergoing trials in a mill and seems to be suitable for commercial use; and a second controller, which may be particularly suitable for cards with ball and bank feeds, is also under trial. Commercial development of the Raper drawing system, incorporating auto-levellers, has now been taken up, and a most encouraging number of firm orders has been placed by British spinners; a great deal of the early work on this new system was done in the Association's laboratories. Much new information about the drafting process has been obtained by the use of radioactive tracers, and considerable progress has also been made in an attempt to understand theoretically how tensions are generated in yarns being drawn from packages, and

how this tension should vary with the dimensions of the package and the position of the twist through which the yarn must pass.

In chemical technology 449 investigations were carried out on behalf of member firms. Scouring experiments continued, and a large-scale trial demonstrated that bulk removal of cellulose acetate fibre from rags is technically feasible. The practicability of dyeing wool at high temperatures without undue damage to fibres has been confirmed, provided the pH of the dye liquor and the time of treatment are kept within limits. Experience has shown that the Association's fineness meter, based on the air-flow method, is quick and reliable and that the accuracy in the mean fibre diameter of tops is at least as high as that obtained with a projection microscope. A rapid method of comparing the strength of two yarns has been devised, which can be used where no strength machine is available. Work in the Biology Department on Scots blackface, Herdwick and Suffolk breeds of sheep has emphasized the importance of the secondary to primary follicle ratio in the development of fine wools, and the effect of breeding and of nutrition on this ratio is being studied.

The use of starch columns together with fraction cutters for quantitative estimation of amino-acids by colorimetric and radioactive methods continued, and by the method of hydrazinolysis the carboxy terminal end-groups of wool have been found to be serine, glycine, threonine and alanine. A study of the effect of dry chlorination on dyed nylon has been completed. Experiments with textiles and ion-exchange resins have shown the electrolytic nature of charge separation by contact between dissimilar polar polymers, the sign of the charge being determined by the excess of freely diffusible ions in the polymer. Complete X-ray data have been obtained for the hydrochloride and hydrobromide of glycol-L-alanine, and a Fourier projection has been determined which gives an accurate picture of the atomic arrangement.

ROYAL SOCIETY DEPOSITORY OF UNPUBLISHED MATHEMATICAL TABLES

THE following is a list of accessions to the Royal Society's depository of unpublished mathematical tables since the publication of the last list in *Nature* (171, 1140; 1953):

(22) Factorisation des nombres $2N^4 + 1$, $N < 1000$ (A. Gloden);

(23) Factorization of $N^4 - 3n^4 - 1$, $0 < N < 1000$ (A. Ferrier);

(24) High-accuracy square- and cube-roots (D. F. Ferguson, O. E. Gwyther and J. O. P. Miller);

(25) A solution of the equation $(y')^2 = y y'$;

(26) Table of

$$F(\beta, \rho) = \frac{2}{\sqrt{\pi}} \frac{\exp(-\rho^2)}{\beta^2} \int_0^\beta I_0(2\rho\eta) \exp(-\eta^2) \eta d\eta;$$

(27) Tables of $F(x) = 2x \sum_{n=0}^{\infty} \{x^2 + (2n+1)^2\}^{-3/2}$ and of $x^{-1}F(x)$;

(28) Table of $G(x) = 6x^2 \sum_{n=0}^{\infty} \{x^2 + (2n+1)^2\}^{-5/2}$;

* Wool Industries Research Association. Publication No. 199: Report of the Director of Research for 1953-54. Pp. 32. (Leeds: Wool Industries Research Association, 1954.)

(29) Tables of

$$f(x) = \sum_{n=0}^{\infty} (-)^n (2n+1) \{x^2 + (2n+1)^2\}^{-1/2}$$

and of $x f(x)$;

(30) Table of

$$f(x, y) = \frac{1}{2\pi} \int_0^{2\pi} \exp(-x \cos \theta - y \cos^2 \theta) d\theta;$$

(31) Tables associated with $\int_0^{\pi} (\cot u + \mu \sin u)^{-1} du$;

(32) Tables of $\int_0^{\pi} \exp(-2\pi i r) dt$

and $\int_0^{\pi} r^{-1} \exp(-2\pi i r) dt$, where $r^2 = a^2 + t^2$;

(33) Tables of integrals associated with the zeros of $\tan z + \tanh z$;

(34) Values and contours of

$$\int_0^{\infty} [\exp(-k) \{J_0(kx) \cosh(ky) - 1\} / \sinh k] dk;$$

(35) Table of

$$f(x) = \exp(-x) \int_0^{\pi/2} \exp(x \cos \theta) \sin^2 \theta d\theta$$

(36) Zeros of the first ten Laguerre polynomials and the corresponding Christoffel numbers;

(37) Tables of $\int_0^{\infty} \exp\{-k^{-1/2} u + i(2ku - u^2)\} du$ for $k = \frac{1}{2}, \frac{1}{3}, 1, 2, 4$ and 8 ;

(38) Tables for the summation of trigonometrical series;

(39) Tables of the incomplete Airy integral;

(40) Tables of the functions associated with the Airy integral for complex arguments;

(41) Tables of the function $O(m, \mu; x)$.

Tables 25-29 were compiled by the Admiralty Research Laboratory; Tables 30-41 by the Admiralty Computing Service.

Further information about these tables may be obtained on application to the Assistant Secretary, The Royal Society, Burlington House, London, W.1.

be integrated, and an opaque mask placed on the illuminated table represents the domain of integration. The photo-electric cell current, which depends upon the incident light energy, can, by suitable calibration, be interpreted as a surface integral. The relationship between the (non-uniform) light distribution on the table and the height and characteristics of the cell is such that, in the absence of the grating, an opaque mask of given area on the table screens the cell from a fixed quantity of light, independent of the position of the mask on the table. Thus without the grating the instrument would function as a planimeter.

In the instrument which is now in use at Fort Halstead, the light-diffusing table is illuminated from beneath by twenty lamps arranged in a ring: the lamps are fed by alternating current and have a 20 per cent modulation. Two types of photo-plate grating, representing the function to be integrated, have been used with equal success, namely, high-contrast and silver deposit on glass plates, both of full-plate size ($8\frac{1}{2}$ in. $\times$ $6\frac{1}{2}$ in.). The light transmitted through any small element of area on the grating is proportional to the value assumed in a corresponding element by the function represented. The plates used (see Fig. 1) have discrete patterning small enough to give sensibly continuous representation of the (continuous) function over the domain of integration. The photo-electric cell is a caesium vacuum cell with a 1-in. diameter light-diffusing 'eye' at a fixed height above the table. The cell current follows the lamp emission, consisting of a constant component plus a ripple. This current is passed to a unit in which the constant component is blocked by a condenser prior to injection into the grid circuit of the first valve. This governs the valve current, which therefore follows the lamp emission and which passes through a sensitivity control to further amplification, rectification and a galvanometer. There is a maximum amplification of 20,000 from cell current to galvanometer current. Thus the galvanometer readings, which are interpreted as surface integrals, are

THE A.D.E. PHOTO-ELECTRIC INTEGRATOR

By J. R. LOWE

Fort Halstead, Nr. Sevenoaks, Kent

THE instrument described in this article is capable of evaluating surface integrals of any function over a domain with any (possibly irregular) boundaries not containing poles of the function. It is necessary to prepare suitable photo-plate representations of the function, together with opaque masks representing the domain of integration: these preparations will be merited in cases such as the survey task with which we were concerned, which entailed the evaluation of very many surface integrals within irregular boundaries. The accuracy obtainable with the instrument is not yet precisely known, as it is still in the development stage, but the order of errors encountered at present is mentioned later.

In essence, the instrument consists of a light-diffusing table, illuminated from beneath, above which a photo-plate grating and a photo-electric cell are arranged. The grating represents the function to

CONVENIENT Suppliers of More Than 3500 Eastman Organic Chemicals

Eastman's staff of skilled organic chemists, extensive production facilities, and rigid quality control have for a generation served the world's laboratories with high-quality organic chemicals.

For research, for analysis, and for industrial requirements there are now over 3500 different compounds that can be obtained through local distributors in most countries. These firms will be glad to furnish you with full information and assist with your orders.

Fig. 2

responsive only to ripple; hence, under normal working conditions, slow variation of ambient light can be tolerated. By normal working conditions we imply that the obscuration of the cell, due to the grating-mask combination, is not too great.

This proviso will be understood from Fig. 2, which depicts the instrument characteristic at the low-illumination end of the curve. In this region there is a departure from linearity due mainly to the combined effects of the cell and rectifier characteristics. The constant component of illumination fixes the operating point A , while the ripple of amplitude R is followed by the rectified current of amplitude r . Hence, provided that A remains on the straight part of AB , which has constant slope, the galvanometer response is a true image of the ripple. If, however, the steady illumination is weak enough (that is, the obscuration great enough), then the operating point will move to B and the galvanometer response will be distorted. We can, of course, calibrate for any operating point, but only when this lies in a region of constant slope can (slow) variations of ambient light be tolerated; in practice, where obscuration is great, additional steady illumination between grating and cell is provided to keep the operating point up.

The instrument has been used successfully to give integrals of a bivariate-normal distribution function over a domain with irregular boundaries. The initial work consists of (i) the preparation of the gratings and masks, (ii) the matching of these to the conditions of the problem, that is, the initial instrument settings, and (iii) calibration of the instrument. These tasks complete, the evaluation of the surface integrals proceeds very rapidly and entails merely placing the masks in position and reading the galvanometer. Calibration is very simple; one merely brings the galvanometer to zero, with a clear table of known proportions of the probability distribution and observes the corresponding galvanometer readings.

The present method of preparing the gratings is to draw diagrams, to a large scale, consisting of alternate bands of black and white to represent a univariate normal distribution. Photographic superposition of two such diagrams, to a reduced scale and with their bands perpendicular, then gives the required grating. Thus, consider a plain white sheet divided into narrow vertical strips each of width $L + D$. We locate the mean of the normal distribution at the central strip and we wish to blacken a band in each strip (for example, that distant σ from the mean measured perpendicular to the strips) such that the remaining white band-width, L , is proportional to the value assumed by the normal distribution (at distance σ from the mean). That is to say, we require:

$$\frac{L}{L+D} = K \exp\left(\frac{-x^2}{2\sigma^2}\right).$$

If, for simplicity, we choose zero blackening at the mean, that is, we choose $D = 0$ when $x = 0$, then we have:

$$\frac{L}{L+D} = \exp\left(-\frac{x^2}{2\sigma_1^2}\right).$$

Likewise, for the second diagram we have:

$$\frac{L'}{L' + D'} = \exp \left(-\frac{y^2}{2\sigma_y^2} \right).$$

If $L + D = L' + D'$, then the strips in the above diagrams when superimposed define a system of small squares. Consider the square located at (x, y) : the proportion of white surface in this square is clearly

$$\frac{L}{L+D} \times \frac{L'}{L'+D'} = \exp \left(-\frac{x^2}{2\sigma_x^2} - \frac{y^2}{2\sigma_y^2} \right).$$

Thus, when a photo-plate grating is prepared from these diagrams, the light energy arriving at the photo-electric cell, via the unblacked areas of the grating, is governed by the binormal distribution function. Fig. 1 depicts a negative of a binormal distribution grating for which $\sigma_1 = \sigma_2$.

The accuracy obtained with the instrument in recent work is shown by the following results. Using square marks to denote the domain of integration, a series of integral values were obtained of magnitude 0 to 1 (they were probabilities). These values were compared with correct values calculated from error function tables, and the standard deviation of the discrepancies was 0.002. A more adequate (and much longer) statement about accuracy could be made, but this would not be reasonable as our work to date has been of a preliminary nature only.

EFFECT OF NUCLEIC ACIDS ON PROTEIN SYNTHESIS AND AMINO-ACID INCORPORATION IN DISRUPTED STAPHYLO- COCCAL CELLS

By DR. E. F. GALE, F.R.S., and JOAN P. FOLKES
Medical Research Council Unit for Chemical Microbiology,
Department of Biochemistry, University of Cambridge

IT has frequently been suggested in recent literature that nucleic acids have an organizing or controlling role in protein synthesis. These suggestions arise from consideration of three main types of experimental evidence: that the rate of growth or of protein synthesis in a variety of cells can be correlated with the nucleic acid content of those cells¹; that changes in the activity or composition of bacterial cells as a result of the action of transforming factors or bacteriophages are associated with addition

of deoxyribonucleic acid to the cells³; and that no convincing demonstration of protein synthesis has been obtained under physiological conditions by proteolytic enzymes. The further suggestion has been made that nucleic acids act as templates accomplishing the organization of amino-acid residues within protein structures^{3,4}. But any proof of the part they play, let alone its mechanism, awaits the preparation of an experimental system which can synthesize protein and on which an effect of nucleic acids can be demonstrated. Such a system has now been obtained by disruption of suspensions of *Staphylococcus aureus* by exposure to supersonic vibration.

Preparation of Disrupted Cell Material

Staphylococci are harvested while in the stage of active growth after 13 hr. incubation at 30°, washed once in water and made into thick suspension (40 mgm. dry weight of cells/ml.) in 10 per cent sucrose solution buffered with 0.03 M phosphate buffer at pH 6.5. The suspension is then subjected to supersonic vibration of 25 kc./sec. generated by a 500-W. Mullard magnetostrictor oscillator, the transducer-cup assembly being cooled in ice throughout the exposure. The time of exposure varies with the type and efficiency of the assembly used; in a typical case, exposure for 10–15 min. at full power reduced the viable count to 0.1 per cent of the original, while complete disintegration of the cells took place in approximately 35 min. If the material obtained after 20–25 min. exposure in such an assembly is centrifuged at 800 g for 7 min., any unbroken cells are removed; the supernatant is turbid and the greater part of the sedimentable material responsible for this turbidity can be centrifuged down in 20 min. at 4,000 g. The sediment so obtained, after one washing in phosphate buffer at pH 6.5, provides the disrupted cell material used for these studies and, on a dry weight basis, represents approximately 3 per cent of the original cell suspension. Electron microscope examination of the sediment shows that it consists of broken cell envelopes each containing a small round mass of electron-dense material in the centre. Chemical analysis shows that the 'cells' have lost approximately half their protein and nucleic acid at this stage. They are non-viable and have no respiration; they are, however, able to form acid from glucose and to use adenosine triphosphate in the presence of hexosediphosphate as energy source for amino-acid incorporation or protein synthesis processes⁵.

Nucleic acid can be removed from these 'cells' by extraction with M sodium chloride or incubation with ribonuclease or deoxyribonuclease. The usual procedure adopted for such resolution has been to incubate the preparation in M sodium chloride for 1 hr. at 37°; this treatment removes approximately 30 and 55 per cent of the remaining protein and nucleic acid, respectively. Incubation with ribo- or deoxyribo-nuclease (100 µgm./ml.) for 1 hr. at 37° removes approximately 75 per cent of the remaining nucleic acid. Electron microscope examination of the disrupted cell material after such treatment shows that the electron-dense material has largely disappeared and that the majority of the 'cells' consist of cell envelopes with only traces of electron-dense substance in their centres. The amount of nucleic acid that can be removed from the preparation increases with the time of exposure to supersonic

vibration; material obtained after 30 min. exposure can be rendered almost free from nucleic acid in this way.

Incorporation of ¹⁴C-labelled Glutamic Acid

If the disrupted cell material is incubated with ¹⁴C-labelled glutamic acid, adenosine triphosphate and hexosediphosphate, labelled glutamic acid becomes incorporated into the protein fraction of the 'cells'. In the absence of other amino-acids, this incorporation ceases after 90–120 min. incubation (see Fig. 1) and the incorporated radioactive glutamic acid can be partially removed by subsequent incubation of the preparation with adenosine triphosphate, hexosediphosphate and unlabelled glutamic acid⁶. It appears that this incorporation takes place as a result of an exchange reaction between glutamic acid residues of the protein and glutamic acid (possibly after activation by adenosine triphosphate) in the medium^{6,7}; the process is not accompanied by any measurable synthesis of protein. It can be calculated that, under optimal conditions, some 5–8 per cent of the total protein glutamate residues undergo such exchange reactions. *Staphylococci* cannot synthesize protein unless a wide variety of amino-acids is provided in the incubation mixture⁴; if a complete mixture of the naturally occurring amino-acids is added to the incubation mixture, incorporation of ¹⁴C-labelled glutamic acid by disrupted cells continues in a linear fashion for some hours (as shown in Fig. 1) and is accompanied by a small but parallel increase in the protein-nitrogen content of the preparation⁷.

Fig. 1. Course of incorporation of ¹⁴C-labelled glutamic acid by disrupted cell preparation. Curve 1A: preparation incubated with adenosine triphosphate, hexosediphosphate and α-carboxy-¹⁴C-glutamic acid. Curve 1B: as for 1A with addition of 0.1 mgm. staphylococcal nucleic acid/ml. Curve 2A: as for 1A with addition of complete mixture of amino-acids. Curve 2B: as for 1B with addition of complete mixture of amino-acids. Counts carried out on protein fraction of preparation in all cases.

If nucleic acid is removed from the disrupted cells by any of the methods mentioned above, the ability of these cells to incorporate glutamic acid, whether in the presence or absence of an amino-acid mixture, decreases markedly, and this ability is restored by addition of nucleic acid prepared from the soluble portion of the supersonic disintegration by the method of Jones⁸. The staphylococcal nucleic acid has been separated into deoxyribo- and ribo-nucleic acid fractions by the method of Dutta, Jones and Stacey⁹ and the fractions cleaned up by treatment with the appropriate nucleases (deoxyribonucleic acid fraction treated with ribonuclease), followed by precipitation of the sodium salts with ethanol, solution in water and dialysis against distilled water. The incorporation of ¹⁴C-glutamic acid under exchange conditions is markedly accelerated by addition of either ribo- or deoxyribo-nucleic acid¹⁰, a system containing 1.0 mgm. dry weight of disrupted cells/ml. being completely activated by 0.08 mgm. ribo- or 0.04 mgm. deoxyribo-nucleic acid/ml.

Exchange reactions are not confined to glutamic acid but take place to varying extents with all amino-acids tested⁴. However, when the effect of resolution and reactivation by nucleic acids was investigated, it was found that the results varied greatly with the amino-acid tested. For example, ribonucleic acid activation of a salt-resolved preparation towards incorporation of glycine, aspartic acid, glutamic acid or alanine, each tested alone, was found to be 550, 210, 150 and 0 per cent, respectively. No procedure yet adopted has resulted in a demonstrable effect of nucleic acid on incorporation of alanine. Fig. 1 shows the progress of incorporation of ¹⁴C-glutamic acid in a salt-resolved preparation with (curves marked B) and without added nucleic acid (curves marked A) when incubation takes place either with glutamic acid as the only amino-acid present (condition for curves marked 1) or with a complete mixture of amino-acids including ¹⁴C-glutamic acid (curves marked 2).

Whether the amino-acid mixture is present or not, addition of nucleic acid has a marked effect on the incorporation, and it seemed possible that the effect shown in curves 2A and 2B might represent an action of nucleic acid on synthesis of protein in the disrupted cell preparation. If this were the case, similar results should be obtained under the conditions of curves 2A and 2B, whichever of the amino-acids in the mixture were labelled with carbon-14. Accordingly, an experiment was carried out under these conditions with either glycine or aspartic acid or glutamic acid or alanine labelled in parallel samples; it was found that the effect of nucleic acid again varied with the amino-acid the incorporation of which was being measured; thus the incorporation of glycine under conditions shown by curve 2B took place, in one experiment, at a rate 120 per cent greater than that under conditions of curve 2A, while parallel measurements of the incorporation of alanine showed no effect due to the addition of nucleic acid. It is clear that such studies of the incorporation of labelled amino-acids cannot be used as a means of studying the action of nucleic acids on protein synthesis as such. This confirms the similar conclusion previously drawn from studies of the incorporation of labelled amino-acids in intact staphylococci^{4,11}.

Synthesis of Protein and Specific Enzymes

After the results described above were obtained, it was decided to abandon the isotope method for

studying protein synthesis and to investigate, instead, changes in protein-nitrogen and in certain enzymes found to be active in the preparations used. The enzyme systems so far investigated (see Fig. 2) are catalase¹², enzymes involved in the formation of acid from glucose¹³, and the adaptive enzyme, β -galactosidase¹⁴. The disrupted cell preparations used were obtained by exposing staphylococci as described above to supersonic disintegration for 25–30 min. and then resolving the active fraction by extraction with *M* sodium chloride. The preparation was incubated at a final suspension density of 0.3–1.0 mgm. dry weight/3.5 ml. in a salt solution buffered at pH 6.2 containing 2 μ moles adenosine triphosphate/ml., 18 μ moles hexosediphosphate/ml. and a complete mixture of amino-acids¹⁵ with each component at a final concentration of 0.5 mgm./ml. To various samples, suitable amounts of deoxyribo-nucleic acid, ribonucleic acid or a mixture of purines and pyrimidines¹⁶ were added; the concentrations of nucleic acids giving optimal responses varied from experiment to experiment between the limits of 0.02 and 0.1 mgm./ml., and experiments were usually conducted over this range of each nucleic acid; the purine-pyrimidine mixture was added at a final concentration of 25 μ gm. of each component/ml. Incubation was carried out at 37° in centrifuge tubes for 1–2 hr., and the disrupted cells then centrifuged down for analysis and enzyme determinations.

Clearer results were obtained with preparations from which nearly all nucleic acid had been removed; in such preparations it has been possible to show a significant development of the three activities investigated and to demonstrate effects of nucleic acid on such development. In some preparations the rate of production of acid from glucose was negligible; but this activity could be developed by incubation in the presence of amino-acids and either nucleic acid or the purine-pyrimidine mixture, amino-acids alone having little effect (see Fig. 2). The catalase activity could be doubled by incubation for 90 min. under appropriate conditions while, since the original cells had been grown in the absence of lactose or galactose, the preparation was initially devoid of β -galactosidase activity. Conditions leading to the development of the three activities are summarized in Fig. 2; in all cases appropriate controls have been carried out, though not shown in Fig. 2, and the development was abolished either if the amino-acid mixture were omitted or if 30 μ gm. chloramphenicol (which inhibits protein synthesis¹⁷)/ml. were added to the incubation mixture. Consequently, it is a reasonable assumption that the activities develop as the result of protein synthesis. Increases in protein-nitrogen of the preparation are not as marked as the increases obtained for some enzymes, probably because the preparation contains non-functional protein in the cell-wall, etc. Incubation for 90 min. with amino-acid mixture alone and in the presence of deoxyribo- or ribo-nucleic acid, or purine-pyrimidine mixture, gave rise respectively to 2, 21, 31 and 20 per cent increase in protein-nitrogen.

The development of the enzyme system producing acid from glucose is markedly stimulated by the presence of the purine-pyrimidine mixture and somewhat less stimulated by the presence of either deoxyribo- or ribo-nucleic acids; the addition of either of the nucleic acids together with the purine-pyrimidine mixture gives less stimulation than the latter alone. This is a complex enzyme system, and

Fig. 2 Development of (A) enzyme system forming acid from glucose, (B) catalase, and (C) β -galactosidase in disrupted cell preparations. Conditions of incubation as indicated with quantities as in text. Time of incubation: A, 90 min.; B, 90 min.; C, 120 min. * 2 per cent galactose present in incubation mixture for experiments on β -galactosidase development. Broken lines represent occasional atypical results.

more clear-cut results have been obtained with the single enzymes studied, catalase and β -galactosidase. Increase in catalase is markedly affected by ribonucleic acid only, deoxyribonucleic acid and the purine-pyrimidine mixture having little effect, while the latter is sometimes found to depress the formation of catalase below that obtained with amino-acids alone. The addition of the purine-pyrimidine mixture to ribonucleic acid decreases the effect of the acid; in some cases the mixture accelerates the effect of deoxyribonucleic acid alone, and on one occasion (as shown in Fig. 2) the two together gave a slightly greater stimulation than ribonucleic acid alone.

The development of the adaptive β -galactosidase system is particularly interesting. In no case has it

been possible to develop this activity in the absence of a suitable inducer such as galactose. In the presence of galactose, amino-acid mixture and the purine-pyrimidine mixture, there is a rapid formation of β -galactosidase in the preparation and the development continues in a linear fashion for up to 3 hr. In 'cell' preparations which are only partially resolved, the presence of amino-acid mixture gives rise to formation of enzyme at a rate 30-45 per cent of that obtained by the further addition of the purine-pyrimidine mixture. With 'cells' at this stage, neither ribo- nor deoxyribo-nucleic acid has any significant stimulating effect although, on three occasions out of twelve tests, a high concentration (0.3 mgm./ml.) of ribonucleic acid obtained from organisms grown in galactose has increased the effect of the purine-pyrimidine mixture although it has had no action in the absence of the latter. In highly resolved preparations, the enzyme formation due to amino-acids alone is small, while the response to the purine-pyrimidine mixture also decreases and can be abolished by treatment of the preparation with deoxyribonuclease. Addition of 0.015 mgm. deoxyribonucleic acid/ml. now significantly stimulates enzyme formation in the presence of amino-acids and restores the response to the purine-pyrimidine mixture to normal; deoxyribonucleic acid extracted from cells grown in galactose has proved two-three times more active than deoxyribonucleic acid extracted from cells grown in glucose. The presence of ribonuclease in such cases abolishes the response to both deoxyribonucleic acid and the purine-pyrimidine mixture.

Incubation of intact *staphylococci* with glucose, amino-acid mixture and the purine-pyrimidine mixture gives rise to nucleic acid synthesis within the cells, the presence of the amino-acid mixture being an essential part of the system¹². The effect of the purine-pyrimidine mixture on the development of certain enzymes in disrupted cell preparations suggests that these preparations may also be able to synthesize nucleic acid under the conditions used. This has been tested by adding ¹⁴C-labelled uracil or thymine to the purine-pyrimidine mixture and determining the incorporation of radioactivity into the nucleic acid of the preparation. No incorporation of thymine was found in any of the conditions tested. When disrupted cells were incubated with ¹⁴C-uracil, adenosine triphosphate, hexosediphosphate and either the purine-pyrimidine mixture or amino-acids separately, incorporation was insignificant; when the purine-pyrimidine mixture and amino-acids were present together, incorporation took place at a rate corresponding to approximately 3 μ mole uracil/hr./mgm. dry weight of preparation; when galactose was added (as for the development of β -galactosidase) in the presence of amino-acids and the purine-pyrimidine mixture, the rate of uracil incorporation increased five-six times. It appears that the disrupted cells can synthesize ribonucleic acid from the purine-pyrimidine mixture and other components of the medium under suitable conditions.

Action of Penicillin on Enzyme Formation

Table 1 shows the effect of the addition of penicillin to the incubation mixture during the development of the various enzyme systems studied. The development of catalase or the acid-producing system from glucose is insensitive to penicillin unless the concentration of the antibiotic is taken to very

Table 1. EFFECT OF PENICILLIN ON DEVELOPMENT OF ENZYME ACTIVITIES IN DISRUPTED CELL PREPARATION

Penicillin concentration (int. unit/ml.)	Per cent inhibition of development of		
	Catalase	Acid formation from glucose	β -Galactosidase
1	4	0	60
30	5	0	78
300	13	0	83

high values; this finding agrees with that previously recorded for the effect of penicillin on the synthesis of cellular protein in intact *staphylococci*¹². The development of β -galactosidase is, however, highly sensitive to penicillin, being 60 per cent inhibited by a concentration of 1 international unit of penicillin/ml. The sensitivities of the syntheses do not appear to depend upon the conditions promoting the formation of the enzymes; thus the sensitivity of either catalase or β -galactosidase development is significantly the same whether formation takes place in the presence or absence of ribo- or deoxyribo-nucleic acid or the purine-pyrimidine mixture. The incorporation of ¹⁴C-uracil which takes place under the conditions of optimal synthesis of β -galactosidase is 65 per cent inhibited by 30 int. units penicillin/ml., whereas that which occurs in the absence of galactose is inhibited to an extent of less than 15 per cent.

Role of Nucleic Acids In Protein Synthesis

Nucleic acids play a part both in the synthesis of proteins and in the incorporation of labelled amino-acids into preformed protein in the disrupted *staphylococci* preparations used in this work. When a single amino-acid is supplied in the medium, it appears that exchange reactions may occur between that amino-acid and corresponding residues in certain of the cell proteins as long as nucleic acid is present. It would appear that either deoxyribo- or ribo-nucleic acid can render amino-acid residues exchangeable, but it is not yet possible to say whether the same or different proteins are involved in the two cases. No clear explanation can be given of the differing degrees of 'resolution' obtained with incorporation of different amino-acids, unless the activation of amino-acid residues which renders them exchangeable is accomplished by specific fragments of nucleic acid, and some of these fragments are more readily removed or damaged than others.

When all the necessary amino-acids are available and conditions are suitable for protein synthesis, the nature of the protein produced would again appear to be determined by nucleic acids. The experimental facts outlined above could be fitted into a mechanism of protein synthesis occurring along the lines of the following scheme, for which no originality can be claimed: the initial organizing structure or template is either deoxyribonucleic acid or a protein complex containing that acid; this structure is not capable of the synthesis of new protein (although it may bring about exchange reactions in the protein portion), but acts as an organizer for the synthesis of ribonucleic acid; once ribonucleic acid has been constructed, then neo-protein synthesis can take place at a rate dependent upon the amount of specific ribonucleic acid catalyst present. It may be that it is the ribonucleic acid which collects, organizes and orientates amino-acid residues before they split away as protein, or it may be that deoxyribonucleic acid combines with and organizes amino-acid residues which cannot combine into a peptide chain until they

have been taken over by the corresponding ribonucleic acid. The comparative effectiveness of ribonucleic acid and a purine-pyrimidine mixture in promoting specific protein synthesis in disrupted cell preparations would then depend upon (1) the ease of synthesis of the specific ribonucleic acid from the purine-pyrimidine mixture, and (2) the stability of the ribonucleic acid once synthesized. Thus, in the case of catalase, the specific ribonucleic acid appears to be stable but not readily synthesized, whereas the formation of β -galactosidase would be explicable if the corresponding ribonucleic acid syntheses were rapid but the product unstable in the absence of inducer. The initiatory role of deoxyribonucleic acid in the case of β -galactosidase formation is shown by the disappearance of response to amino-acids and the purine-pyrimidine mixture in highly resolved preparations treated with deoxyribonuclease, and recovery of response by addition of small amounts of deoxyribonucleic acid. The response to the purine-pyrimidine mixture is accompanied by synthesis of ribonucleic acid, and its essential role in β -galactosidase formation is shown by the loss of response to the purine-pyrimidine mixture and deoxyribonucleic acid in the presence of ribonuclease.

It has been previously shown that penicillin, at growth-inhibitory concentrations, inhibits the incorporation of specific amino-acid residues (under exchange conditions), and it has been suggested that this inhibition results from a blocking of specific interactions between nucleic acids and proteins which would lead, in the growing cell, to failure of the formation of specific proteins¹³. In the *staphylococci* used for this work, β -galactosidase is an example of a protein the formation of which is inhibited by penicillin. The inhibition is again accompanied by inhibition of synthesis of ribonucleic acid.

GENETIC POLYMORPHISM IN THE RABBIT IN TASMANIA

By PROF. H. N. BARBER
University of Tasmania

THE rabbit (*Oryctolagus cuniculus*) was introduced into Tasmania soon after the first settlement in 1803. It was first recorded wild in large numbers on a few estates in the lower midland pastoral areas north of Hobart in 1827¹. During the next fifty years it spread over the midlands pastoral region, occupying country with open eucalypt savannah

vegetation and a rainfall of 20-30 in. Towards the end of the nineteenth century it colonized the central plateau region around Great Lake, a region more than 3,000 ft. above sea-level and with a rainfall of 30-40 in. The north-west coastal region and the north-east mountains were first colonized extensively during the past 30-40 years. To-day the rabbit can be found over most of the eastern two-thirds of the island.

In the west the spread of the rabbit has been limited by natural ecological barriers. Apart from a coastal belt about thirty miles wide running along the north-west coast, there are no rabbits in the western third of the island. This area is approximately limited by the 60-in. isohyet. Within this area the main plant communities are dense rain forest with *Nothofagus*, *Atherosperma*, *Anodopetalum*, etc., and peaty button-grass plains with various Cyperaceae (*Mesomelaena*) and Restionaceae dominant. The forest occurs on soils of a higher mineral status and better drainage, while the button-grass community develops on wet, acid soil of very poor mineral status. Where these communities have remained in their virgin state, the rabbit has not penetrated.

Agricultural development of the button-grass community has proved impossible up to the present. Numerous attempts have been made to clear the rain forest for agricultural and pastoral development. In regions of high rainfall (more than 60 in.) and above elevations of 1,500 ft., such attempts have usually failed. The cleared land is now a wilderness covered with dead logs, bracken, and the more resistant undershrubs of the rain forest (for example, *Drimys*, *Leptospermum*, *Cassinia*). In the north-west and north-east dense populations of rabbits exist on such land.

In less than 150 years the rabbit has, thus, colonized a wide variety of habitats in Tasmania. During the summer of 1952-53, an attempt was made to determine if any genetical differentiation had occurred in response to the colonization of the different habitats. Several conspicuous colour variations occur in the rabbit. Counts of the frequency of these variations were made on living populations. In order to avoid bias owing to the different degrees of conspicuousness, the technique adopted was to walk slowly around an area, counting the rabbits as they bolted for cover. In good rabbit country a twenty-minute circuit will result in a count of between 100-200 rabbits. Usually two independent observers made a count on opposite sides of the road. The two counts agreed very well and have been grouped in the data. The majority of counts have been made along transects approximately perpendicular (running north-south) to the northern coast line. The transects start in rich farmlands on the coast and end 15-30 miles inland at altitudes of 1,500-3,000 ft. beyond which the rabbit has scarcely penetrated.

During the survey, nearly 10,000 rabbits were counted. Among the conspicuous colour variations noted are: (1) black, (2) 'blue', (3) yellow, (4) dutch, (5) irregular piebald, and (6) white. Of these, only the black and blue reach frequencies of more than 1 per cent. Among the 10,000 rabbits counted, 10 were dutch (8 agouti, 2 black), 3 yellow, 1 irregular piebald and 2 white. In addition to these major colour variants there are a number of minor variants only visible on trapped animals. They include white spots or stripes on nose and forehead with or without

white forepaws. Many of the blacks have a denser or lighter sprinkling with white hairs, and some of them have extensive dorsal areas of chocolate-brown fur. No accurate data exist on the frequencies of these minor variations.

Fig. 1 gives data on the frequency of blacks obtained on three of the transects. The most easterly transect (Great Lake-Deloraine) is about thirty-five miles east of the Nietta transect with the Hampshire transect another 15-20 miles farther west. It will be seen that the blacks increase in frequency to a maximum of 20-35 per cent of the total population in regions of high rainfall at elevations of more than 1,500 ft. Below this region the frequency of blacks falls off until at the coast it is less than 1 or 2 per cent. This clinal pattern is apparent over a region of approximately seventy miles along the north-west coast from Deloraine to Preolenna. There is some evidence that the clines are steepest in the middle of this range, the maximum black frequency decreasing both to the east and west of the central Nietta-Moina region. The same pattern exists on the north-east mountains although here only a single transect has been made. Over the rest of the island isolated counts are available. They show that the frequency of blacks is low (< 2 per cent) in the midland savannah country. The frequency rises to about 10 per cent in the open *Eucalyptus gigantea* forests on the central plateau around Great Lake. Frequencies higher than 20 per cent are always associated with cleared rain forest or mixed eucalypt-rain forest

Fig. 1. Diagram of three transects running approximately south-north. Each transect ends near the coast of Bass Strait. An altitude section (vertical magnification approximately $\times 250$) is given immediately below the graphs showing frequency of black rabbits. Total rabbits counted is given for each transect. Minimum number of rabbits used in estimating frequency at any one point is 48; maximum 199; mean 123.

with a rainfall of more than 50 in. These relationships are best shown in Fig. 1, the frequency of blacks rising to a maximum in the partially cleared rain forest of the wet escarpment, and decreasing both on the central plateau and on the coastal plain where the vegetation, because of the lower rainfall, is open eucalypt forest. No attempts to estimate accurately the density of the rabbit populations were made. But there appears to be no correlation of the frequency of blacks with density or total numbers. A dense population can show a high or a low frequency of blacks, depending on the ecology of the site.

It is possible that the blue type shows a somewhat similar pattern of distribution; but accurate scoring of this type would involve large-scale trapping. The maximum frequencies are, however, considerably lower than those of the black.

The pronounced ecological correlation shows that the cline in the distribution of the blacks has been built up under the action of natural selection. The wetter regions, usually at altitudes of 1,500–2,500 ft., in some way favour the black. The situation in many respects parallels the distribution of the black hamster (*Cricetus cricetus*) in the southern U.S.S.R. Gershenson⁵ has shown that the black hamster may reach frequencies of more than 75 per cent in the humid forest-steppe region of its range. In the dry forest-steppe or mountain forest the frequency of black falls to zero. Guiler⁶ has also recently shown that the distribution of the black and grey phases of the Tasmanian brush possum (*Trichomys vulpecula*) shows a pronounced ecological correlation, the black phase again being correlated with heavy rain forest country (cf. Pearson⁴). In all three cases it is impossible at present to specify the advantages conferred by the black genotype in the wetter regions. It is possible that temperature may also be effective in selection. The rain forest localities probably show much less extreme temperature variations than either the alpine eucalypt or the savannah eucalypt forests.

Nothing is known of the genetics of the Tasmanian black rabbit. A few mixed litters of agouti and black and agouti and blue have been dug out. Gershenson⁵ has shown that the black type of hamster is caused by a single dominant gene which he thinks may be homologous to the extension black, *E^D*, of Punnett (see Castle⁷) in the rabbit and black rat. If the black in the Tasmanian populations is caused by this gene, steels (heterozygotes *E^DE*), in the presumably random mating population, should be commoner than the homozygous blacks (*E^DE^D*). The genetical constitution of the 'blues' in Tasmania is also unknown. They vary considerably in colour. It is unlikely that they could represent the heterozygous steels since their frequency is much lower than that of the black. It is possible that there has been a selective shift of dominance so that *E^D* has become completely dominant over *E*. But it appears more likely that we are dealing with the recessive black (*aa*). Breeding experiments are planned to determine the genetics of these colour types.

It is perhaps significant that the maximum frequency of black observed is 37 per cent. It is more usually 25–30 per cent along the border of the rabbit-free zone in the north-west. If black is recessive, this lower frequency would give the maximum frequency of heterozygotes in a random mating population. It is thus possible to envisage a selection system based on a heterosis effect in the humid rain

forest region, selection tending to equalize the allelic frequencies in this region. The black, to human eyes, is much the more conspicuous animal, particularly in the open savannah pastoral districts. Calaby⁸ has shown that bird predators may be responsible for the death of 4 per cent of kittens in the Murray Valley region of Australia. The birds may thus exert a counter-selection on black in the open country. Removal or lessening of this selection by increased cover may be one of the factors contributing to the establishment of the cline. Thus, the system of selection in the Tasmanian rabbits may show interesting analogies to that suggested by Ford⁹ to explain the origin of industrial melanism in several species of moths. In the moths a heterosis effect is absent, so that when selection against the dominant black mutants is relaxed, the frequency of the black allele rapidly approaches unity.

As regards the time taken to establish the clines, and whether a true equilibrium has been reached, little is definitely known. A maximum time for establishment is certainly less than fifty years. The Parrawe region near Waratah, where blacks reach a frequency of 25–30 per cent, was cleared between 1915 and 1925. Rabbits, according to local report, were absent in the primeval forest. Blacks have been present in the north-east mountains for more than forty years. It thus appears probable that a cline may be established in so short a time as twenty years. If this is the case, it is also probable that equilibrium has been reached. Southern¹⁰ has shown that migration distances are remarkably small for the rabbit in English warrens. If this is so under Tasmanian conditions, it would appear that the cline is a true selection cline and not due to a balance of selection and long-distance migration.

During the survey occasional evidence of myxomatosis was seen. The incidence of the disease in Tasmania since its illegal introduction in the late summer of 1951–52 has been very local. Of the three clines illustrated, the Great Lake-Deloraine cline had been slightly affected around Deloraine (between 20–30 miles). Dense rabbit populations still exist here and no difficulty was experienced in obtaining counts of 100–200 rabbits. It will be interesting to attempt to follow the changes in population density and genetic constitution if sudden fluctuations in density of the rabbit population occur. There is no evidence that any of the mutations studied in this survey confer any increased resistance or susceptibility to attack by the virus. However, the existence of mutants affecting coat colour at possibly more than five loci shows that the Tasmanian rabbit populations may possess an amount of genetic variability affecting other characteristics sufficient to allow them to adapt themselves to myxomatosis almost as quickly as the virus is evolving strains of less virulence¹¹.

I wish to thank Mr. W. D. Jackson and Mr. R. H. Cruickshank for much assistance during the field survey. [March 22.]

A Crystalline Material with Xanthine Oxidase Activity

In the course of investigations into the preparation, purification and chemistry of xanthine oxidase from cow's milk, as part of a larger programme of biological and chemical research into functional and structural cellular constituents, we obtained a crystalline material with pronounced enzyme activity.

It was produced by the slow addition, below 0° C., of ethanol (final concentration, 2-7 per cent) to an aqueous concentrate, referred to as 'starting concentrate' (salt content: *M*/100 phosphate buffer, pH 6.2), discarding the initial precipitates. The preparation of these fractions from buttermilk whey followed published methods^{1,2}, with certain modifications. Under the microscope, small needles, often bunched together in rosettes (Fig. 1), are recognizable. The values in Table 1 give an idea of the properties of two batches, A and B, of the crystalline materials as compared with the corresponding 'starting concentrates' and the mother liquors of crystallization.

It can be seen that although considerable enzyme activity (columns *e* and *f*) is retained by the mother liquors of the crystals, the latter show an improved 'protein/flavin' ratio (column *d*). On the basis of the calculation given in footnote (*f*), the Q_{O_2} of our best preparation, namely, crystalline material B, was 1,580 at 23° C., as compared with Morell's³ value of 694 at 19° C. It is interesting to mention here that when some of the fractions were tested against methylene blue, the rates of decoloration with hypoxanthine and xanthine as substrates in equal concentrations were the same (Q_{MB} c. 1,400; Corran *et al.*⁴ reported Q_{MB} 2,420); with acetaldehyde as substrate we found Q_{MB} c. 4,200 (Corran *et al.*⁴ give 3,500).

With regard to the composition of enzyme preparations, Philpot⁵ has distinguished in the concentrate of Corran *et al.*, just mentioned, three components, called γ , δ (main fraction) and ϵ , when submitting it to examination in the ultracentrifuge. Sedimentation experiments with our materials indicated that ϵ was barely detectable in all our runs, while γ was present in the starting concentrate A but was reduced in

Fig. 1. Crystalline material A. ($\times 375$)

the crystalline material A and B to negligible amounts (Figs. 2 and 3). This was reflected in a fall in the corresponding 'protein/flavin' ratios (Table 1, column *d*). The colour was associated with the main fractions in each case. Preliminary molecular weight calculations based on such ultracentrifuge results indicated a molecular weight of about 200,000 for our main fraction. Electrophoresis experiments, so far carried out with 'starting concentrates' only (by Mr. D. W. F. James), showed on the whole one peak.

In accord with Green and Beinart⁶, molybdenum was found in all fractions; while crystalline material B came up to c. 0.03 per cent⁶, all other fractions contained rather less, namely, c. 0.02 per cent. FAD estimations carried out fluorimetrically⁷ infer an FAD/Mo ratio of approximately the published order^{8,11}. Richert¹² has recently reported the occurrence of iron in his milk xanthine oxidase preparations. While we found iron¹³, we are not yet certain whether this metal forms an integral part of the active lacto-xanthine oxidase molecule.

It is more than likely that even our best crystalline material obtained to date represents a mixture of active xanthine oxidase and perhaps slightly denatured enzyme of the same molecular weight; the difference between crystals A and B can be clearly

discerned in Table 1; the ratio $\frac{\text{activity (units/L)}}{E(450 \text{ m}\mu)}$

Table 1

<i>a</i>	<i>b</i>	<i>c</i>	<i>d</i>	<i>e</i>	<i>f</i>
Material	Batch	Dry weight (gm.)	Ratio: Protein/Flavin*	Ratio: Activity (units/L)/ <i>E</i> (450 m μ)	Ratio: Activity (units/L)/ <i>E</i> (290 m μ)
'Starting concentrate'	A	0.32	7.4	39	5.3
	B	1.93	8.5	62	7.3
Crystalline material	A	0.13	5.3	32	6.1
	B	0.35	5.1	63	10.4
Mother liquors	A	0.13	7.5	34	4.4
	B	0.48	12.4	57	4.6

a, 'Starting concentrate' as in text; crystalline material centrifuged, washed and redissolved; mother liquor without washings.

c, Calc. from *E*(290 m μ) with *E*(1%, 1 cm) = 11 (value based on Cl₂OCC₂H method (ref. 3) and Kjeldahl-nitrogen).

d, Ratio: $\frac{E(290 \text{ m}\mu)}{E(450 \text{ m}\mu)}$; pH 7.2.

e, Spectrophotometric assay method (refs. 4 and 5), with xanthine, pH 8.2, 23° C. Units = $[(\Delta E(1 \text{ cm}, 295 \text{ m}\mu)/\text{min}) \times \text{overall enzyme dilution} \times \text{volume of sample (in litres)}]$.

f, This is related to conventional Q_{O_2} = above ratio $\times 152$ [taking *E*(1%, 1 cm) = 11 and ΔE (oxid. 1 μ gm. xanthine/ml.) = 0.064] (see ref. 5).

Fig. 2

Fig. 3

is regarded as being largely dependent on the relative amounts of active and inactive enzyme in the sample (see also ref. 5). So far we have not been successful in separating the functionally active portion from the closely related inactive one, as no operations with the crystalline or other material in our hands have yet brought about an improvement in the above ratio. The nature of the difference between active and inactive enzyme, as well as their chemistry, will form the subject of further studies. Details of our findings, reported briefly above, will be published elsewhere.

We are grateful to Prof. A. Haddow for his support, encouragement and continued interest. We wish to thank Prof. H. D. Kay and Miss H. Chapman, of the National Institute for Research in Dairying, for their assistance in supplying us with buttermilk, Dr. M. Dixon and Dr. H. M. Kalekar for their helpful criticism, and Dr. P. M. Cowan and Dr. W. E. Seeds for crystallographic advice. We acknowledge technical assistance by Mrs. K. Tussler and Mr. T. Stebbings. This investigation has been supported by grants to the Royal Cancer Hospital and Chester Beatty Research Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

Stereochemistry of Certain Analgesics

We are investigating the configurational relationships existing among a group of optically active analgesics all of which possess one asymmetric centre. In 'Methadone' and related compounds it has been shown¹⁻³ that almost the whole of the analgesic activity resides in one of the isomers.

We have established that the analgesically active isomers '(-)-methadone' ((-)-6-dimethylamino-4:4-diphenylheptan-3-one), (-)-ethyl-1:1-diphenyl-3-dimethylaminobutyl sulphone, and (+)-3-dimethylamino-1:1-(2'-thienyl)-but-1-ene, possess identical configurations which are related to D-(-)-alanine. These relationships were established in the following way. The hydrolysis of (-)-ethyl-1:1-diphenyl-3-dimethylaminobutyl sulphone gives (-)-3-dimethylamino-1:1-diphenylbutan-1-ol⁴. This alcohol, after dehydration followed by reduction, gave (+)-3-dimethylamino-1:1-diphenylbutane, which was also obtained from (-)-4-dimethylamino-2:2-diphenylpentane nitrile, the precursor of (-)-methadone. L-Ethyl-3-dimethylaminobutyrate, derived from phthaloyl-L-alanine via an Arndt-Eistert reaction followed by reductive methylation, was treated with phenyl magnesium bromide to yield (+)-3-dimethylamino-1:1-diphenylbutan-1-ol. Reaction of this same ester with thienyl lithium gave (-)-3-dimethylamino-1:1-(2'-thienyl)-butan-1-ol, which gave (-)-3-dimethylamino-1:1-(2'-thienyl)-but-1-ene on dehydration.

In a recent communication, Bick⁵ has advanced evidence from which he concludes that morphine is configurationally related to L-(+)-alanine. His argument relates the two substances via apomorphine and laudanone and depends on the validity of a method of assigning configuration first employed by Leithe^{6,7}. Leithe maintained that the specific rotation of bases possessing analogous asymmetric centres and of like configuration are displaced in the same direction when examined in a series of solvents of increasing polarity.

Because the validity of Leithe's method has not been rigidly established, we have determined the specific rotations, in a series of solvents, of the compounds shown in Table 1. The configurations of these compounds are identical and have been established as described above. It is evident that in this series no relationship exists between configuration and direction of specific rotational change brought about by an increase in the polarity of the solvent.

We are therefore of the opinion that the method used by Bick to establish the relationship of morphine and apomorphine to the L-amino-acids is of doubtful value. Furthermore, we consider that the configurational assignments given by Leithe to alkaloids of the laudanone and berberine type are not conclusive.

The identical configurations of the analgesically active isomers reported in this communication; the antagonistic action exhibited by N-allylnormorphine ('Nalorphine') towards morphine and many of the synthetic analgesics; the antagonistic action towards morphine shown by (-)-N-allyl-3-hydroxymorphinan but not by the corresponding (+) isomer⁸; the identical configurations of (-)-N-allyl-3-hydroxymorphinan and (-)-3-hydroxy-N-methyl-morphinan⁹ (the isomer which is analgesically active whereas the (+)-isomer is inactive) give further support to the statement¹⁰ made some time ago by one of us (A. H. B.) that "before analgesic action can be mediated directly or indirectly, it is possible that the stereochemical

configuration of the drug must be complementary to that of a certain tissue surface or enzyme system". The presence of specific receptor sites for analgesic action is now a probability rather than a possibility.

A detailed account of the investigation of certain structural aspects of analgesics will be published elsewhere.

Influence of Vitamin C on the Utilization of Sulphate labelled with Sulphur-35 in the Synthesis of Chondroitin Sulphate of the Costal Cartilage of the Guinea Pig

It has been reported that sulphate when administered to the rat is retained by cartilage, bone and bone marrow¹, and it is now further established that the sulphate is mainly incorporated into the chondroitin sulphate of the cartilage²⁻⁴. Since the utilization of the sulphate administered in the formation of chondroitin sulphate lends itself to quantitative determinations, this was used by us for studying the influence of vitamin C on the formation of this sulphuric ester in the costal cartilage of the guinea

pig. The evidence so far obtained by employing the histological techniques is not conclusive. Thus, Højer⁵, who was the first to observe the atrophy of collagen in the cartilage in scurvy, was not able to find any difference from the normal in regard to chondroitin sulphate by staining the sections with methylene blue. Contrary to the above observation, Meyer⁶, using basic metachromatic dyes, did not find any chondroitin sulphate in the cartilage of scorbutic guinea pigs.

Guinea pigs, eight weeks old and weighing 246-304 gm., were used in these studies. They were given large quantities of green leafy material for one week before the experiment and the scorbutic diet⁷ for the whole of the experiment. In addition, each guinea pig received 1 ml. of cod liver oil twice a week. Fresh tap water was also given daily. They were weighed once in four days. Twenty-six guinea pigs, consisting of equal numbers of males and females, were maintained on the scorbutic diet for nineteen days, and the typical symptoms of scurvy such as cessation of food intake, loss in weight and the tenderness of the joints were noticed. During the third week, three males and three females died. Twenty-six guinea pigs, consisting of equal numbers of males and females, received, in addition to the above scorbutic diet, 4 mgm. L-ascorbic acid *per os* each day. One guinea pig in the male group was found to be sick on the second day of the experiment and was discarded. The rest were healthy throughout the experimental period and steadily gained in weight.

On the nineteenth day of the experiment, the guinea pigs, both deficient and normal, were given intraperitoneally 0.02 mc. sodium sulphate-35 in dilute aqueous solution per 100 gm. body-weight. After the administration of the sulphate, they were maintained for 48 hr. under the dietary conditions described above. At the end of the period they were killed, and the costal cartilage was removed. The chondroitin sulphate from the cartilage was prepared

Fig. 1. Radioactivity of barium sulphate obtained from chondroitin sulphuric acid, prepared from the costal cartilage of normal and deficient guinea pigs. Normal—basal diet + 4 mgm. vitamin C/day. Deficient—basal diet only

according to the method of Jorpes⁶ as modified by Strandberg⁷ and by Boström⁸.

80 mgm. of chondroitin sulphate was hydrolysed with 5 ml. of 6 *N* hydrochloric acid in a steam-bath for 4 hr. The sulphate was precipitated as barium sulphate and collected in a tared goodish crucible, ignited and weighed. 20 mgm. of barium sulphate was suspended in 50 per cent alcohol and collected on a filter paper on a perforated aluminium disk. The precipitate was washed with absolute alcohol and ether, and radioactivity was measured in a Geiger-Müller counter with a 2.1-mgm. per sq. cm. mica end window. After the counts were taken, the samples were dried at 105° C. and the weights were checked.

The results in Fig. 1 show that the sulphate administered is incorporated into the chondroitin sulphate of the costal cartilage. The utilization of the sulphate in the formation of chondroitin sulphate was not significantly affected by variations in sex. But, however, there is a significant difference between normal and deficient guinea pigs in their utilization of the administered sulphate in the formation of chondroitin sulphate. The average incorporation in the deficient animal was about one-third that of the normal. The esterification of the sulphate group appears to be a very sensitive indicator for the metabolic disturbances in the cartilage in scurvy.

We are indebted to Prof. Erik Jorpes for facilities and for his interest during the course of this investigation, and also to Prof. Håkan Rydin, who offered us facilities for conducting the animal experiments in the State Pharmaceutical Laboratory.

Diffusion of Alkaline Phosphatase to Characteristic Intracytoplasmic Sites of Activity

WHILE using superimposed frozen-dried sections of rat kidney for the study of diffusion phenomena¹ in the Gomori²-Takamatsu³ technique for alkaline phosphatase, it was observed that faint staining of the brush border regions in the underlying inactive section in very occasional tubules. This result was obtained after moderately prolonged incubation, even when inactivation of the underlying section was effected by heat. The appearances suggested that the enzyme itself, enzyme activator or phosphate ion was diffusing into the underlying section, and prompted further experiments to demonstrate enzyme diffusion to characteristic positions in the cell⁴.

Fig. 1. Frozen-dried section of rat kidney heated at 95° C. for one minute, incubated at 37° C. in kidney mash suspension for one hour, washed in distilled water and incubated in glycerophosphate medium for four hours.

Frozen-dried 5- μ sections of rat kidney were deparaffinized in xylene, immersed in absolute alcohol for three minutes and passed through 50 per cent alcohol to water. The slides were then immersed in distilled water at 95° C. for one minute, which was shown in the control sections to inactivate the enzyme completely. They were next incubated at 37° C. in a solution containing 0.4 per cent sodium veronal and 0.4 per cent calcium nitrate to which was added a fine mash of fresh rat kidney. This solution had a pH (glass electrode measurements) of 8.7 before and 8.5 after one hour's incubation. After brief washing in distilled water the slides were incubated in the usual glycerophosphate medium, and sites of activity demonstrated by final precipitation of cobalt sulphide. After treatment of the inactivated section for one hour in the kidney mash suspension and subsequent incubation with substrate for four hours, staining was observable in the brush border regions of the tubules and in most nuclei throughout the kidney (Fig. 1). Shorter times of incubation in the two media produced similar but less intense results. Enzyme transfer could similarly be effected to heat-inactivated frozen-dried sections of rat duodenum.

Sections were also inactivated with 0.25 per cent nitric acid, 0.1 *N* hydrochloric acid, 10 per cent acetic acid and saturated mercuric chloride solutions. Substantially similar results were obtained after incubation with the mash suspension, although the nuclear appearances varied with the method of inactivation. With mercury-inactivated sections, treatment with a filtrate from a mash suspension previously heated to 95° C. for one minute resulted in reappearance of enzyme activity in characteristic sites. This filtrate had no effect in restoring enzyme activity in heat-inactivated sections.

Similar results were obtained with a mash suspension in distilled water with sections inactivated by mercuric chloride; but the nuclear staining was much less intense than in sections treated with the mash suspension in a sodium veronal-calcium nitrate solution. Mash suspended in distilled water had only a slight effect on sections inactivated with 0.25 per cent nitric acid, brush borders and very occasional nuclei being just visible. The fact that heated homogenate will not reactivate heated sections excludes the possibility that the diffusing substance is phosphatase activator (unless the latter is heat labile).

These findings point conclusively to the diffusion of alkaline phosphatase to normal as well as to other sites in the cell. Taken in conjunction with those of Gomori¹ and Novikoff², they suggest that something in addition to the enzyme and not calcium ions or sodium veronal is necessary to effect such transfer. There is some indication, however, that these latter substances may facilitate enzyme diffusion or its attachment in the cell. Such findings do not detract from the usefulness of the method provided that properly designed controls are used in any particular study.

The demonstration of diffusion of alkaline phosphatase and its attachment to other, as well as to characteristic, sites in the cell suggests that erroneous conclusions may be drawn from analysis of its activity in homogenate fractions. The use of histochemical controls thus seems to be essential in such studies.

I wish to express my gratitude to Prof. J. F. Danielli for his guidance in this and other studies on alkaline phosphatase.

A Quantitative Method for Enzyme Cytochemistry applied to Alkaline Phosphatase

In the Gomori-Takamatsu technique for localizing alkaline phosphatase, tissue sections are incubated in a solution containing a phosphate ester and calcium ions. The phosphate ions liberated as a result of enzyme activity are precipitated in the section as calcium phosphate, which is made visible by converting it to cobalt sulphide. The cobalt sulphide is dark brown and gives only a rough indication of the degree of enzyme activity. A quantitative method¹ has recently been developed for measuring the mass of substances (other than water; that is, dry mass) in cells. It has been shown that the dry mass can be determined from measurements of optical path difference which can be made with an interferometer microscope. This note describes measurements made with this technique of the amounts of calcium phosphate deposited as a result of phosphatase activity. We have found that the interferometer-microscope method can be used to study the magnitude of possible artefacts due to diffusion of

enzyme and diffusion of the calcium phosphate. We have also found that interferometry provides a most promising approach to the quantitative determination of enzyme activity at sites in cells.

Previous observations by Moe² with the Gomori-Takamatsu technique indicated that after initial precipitation large-scale diffusion of calcium phosphate may occur from the sites of precipitation to other sites in the section. For example, after about one minute's incubation a heavy deposit of calcium phosphate was found in the intestinal brush border. But after an hour's incubation the brush border appeared to contain no calcium phosphate, and other previously negative sites now became positive. Ruyter³ showed that these results were open to another interpretation, namely, that the calcium phosphate precipitated in brush borders changes its reactivity and can no longer react with the Gomori-Takamatsu reagents. Observations⁴ by phase-contrast microscopy confirmed Ruyter's observations that the processes discovered by Moe do not, in fact, involve a diffusion but rather a change in the physical state of the calcium phosphate. However, unlike the interferometer microscope, the phase-contrast microscope gives only a rough indication of the amount of calcium phosphate.

In our experiments, frozen-dried 4- μ sections of either rat kidney or duodenum, fixed in absolute alcohol for three minutes, were mounted in water in a chamber for continuous observation and measurement with a Dyson⁵ interferometer microscope, made by Cooke, Troughton and Simms, Ltd., objective numerical aperture 1.3. The optical path difference of a site in the brush border was first determined and the section then perfused with a solution of pH 9.3 containing 0.4 per cent sodium glycerophosphate, 0.4 per cent sodium veronal, 0.2 per cent calcium nitrate and 0.04 per cent magnesium chloride. The increase in optical path difference due to deposition of calcium phosphate was recorded as a function of time. Fig. 1 shows results obtained with the brush border of the rat kidney. The rate of deposition is approximately constant for about twenty-five minutes and then slowly diminishes with time. The calcium phosphate was removed from the section with buffered distilled water (pH 7.0) and the section again perfused with the same substrate solution at pH 9.3. Measurements at the same site in the brush border showed the same rate of increase of calcium phosphate as found originally (Fig. 1). We have repeated these experiments six times on a single section (total incubation time, three hours) and have

Fig. 1. Increase in optical path difference (proportional to mass of calcium phosphate per unit area) in kidney brush border during first incubation (O) and second incubation (x).

found that the rate of deposition of calcium phosphate is unaltered within the limits of experimental error. These results indicate that under these conditions the amount of enzyme activity in the brush border of rat kidney remains constant.

In order to find out if calcium phosphate, once formed, can diffuse, the section containing calcium phosphate was immersed in the incubation solution without substrate. After twenty-four hours in this solution at pH 9.3 no change in optical path difference in the brush border, and hence no change in amount of calcium phosphate, could be detected. Therefore, under these conditions calcium phosphate apparently does not diffuse once it has been precipitated.

An important advantage of this technique is that the enzyme activity at one site in one cell can be measured repeatedly under various conditions and a check finally made to see if the enzyme activity under the initial conditions remains unchanged. The following factors which affect both the rate of liberation of phosphate ions and the rate of deposition of calcium phosphate are being investigated: pH; temperature; type and concentration of substrate; concentrations of calcium ions, buffers and activators. The rate of deposition of calcium phosphate during the linear phase, per unit dry mass of tissue, under certain defined conditions of pH, etc., may be used as a quantitative measure of enzyme activity. A full report of these investigations will be published elsewhere.

This technique can be used for the cytochemical study of any other enzymes which, as a result of their activity, produce a measurable change in optical path difference.

We wish to thank Prof. J. T. Randall for his encouragement and for providing facilities for this work, and Dr. L. G. Ball for his guidance in the freeze-drying of tissues. Part of the expense of this research has been defrayed by a grant from the Rockefeller Foundation.

Chemical Composition of the Golgi Apparatus in the Exocrine and Endocrine Cells in the Pancreas of the Mouse

It has recently been shown that pancreas cells (exocrine and endocrine) contain a canal-like Golgi apparatus distinct from all other cell inclusions¹. Since then I have used various histochemical tests to determine the chemical composition of this canalicular structure.

It has often been suggested that the Golgi apparatus contains a lipid capable of reducing silver nitrate

and osmium tetroxide. In support of this view, I have found that when pancreatic tissue is treated first with lipoidal solvents (ether-alcohol, acetone) and then by Aoyama's silver method, there is a total failure to impregnate any inclusions. However, the apparatus remains uncoloured when Baker's² sudan-black method for lipids is used. The reason for this latter result appears to be that the lipid is 'masked' in some way, for it can be coloured with sudan black if the tissue is fixed in Aoyama's fluid, treated with 1½ per cent silver nitrate for 17 hr., washed and embedded in gelatin. In an attempt to determine whether this lipid contains a phospholipin, I used the acid hamatin test exactly as described by Baker³ and, in addition, after the previous use of silver nitrate as an 'unmasking agent'. The full results, in both cases, are as follows: Golgi apparatus = negative; mitochondria = positive; lipoidal bodies = negative; zymogen granules = positive; islet granules = positive.

At least two significant points have emerged from the use of the acid hamatin test. First, I have shown previously¹ that sudan black does not colour zymogen or islet granules (and only occasionally mitochondria) and yet all contain a phospholipin. Therefore a negative result with sudan black does not prove the absence of certain lipids (for example, phospholipins). Secondly, the results seem to disprove the main conclusion reached by Palade and Claude⁴ that the Golgi apparatus is an artefact produced by the action of classical fixatives (particularly Aoyama's fluid) on inclusions rich in phospholipins. My work indicates that: (1) the Golgi apparatus does not contain any phospholipins, and (2) inclusions containing phospholipins (mitochondria, zymogen granules and islet granules) are not distorted in any way by the action of Aoyama's fixative.

Attempts have been made to decide whether the Golgi apparatus contains a protein or a carbohydrate. Weigl⁵ managed to stain bleached Kopech preparations with resorcin-fuchsin, which usually stains proteinaceous connective tissue (see Baker³). However, when fresh resorcin-fuchsin, made up from Weigl's original formula, was used on bleached Aoyama preparations in pancreas cells, there was a total failure to colour the apparatus. Millon's test for protein also gave a negative result. Negative results were obtained for glycogen and mucin (Bauer-Feulgen test⁶) and mucopolysaccharides (Evan's blue method used in conjunction with freeze-drying⁷). Nevertheless, there is still reason for believing that the Golgi apparatus does contain a protein and/or carbohydrate, since it is preserved by freeze-drying⁸.

It has often been suggested that vitamin C may be associated with the Golgi apparatus (see Bourne⁹). Accordingly, Bourne's test⁹ for ascorbic acid was used. A negative result was obtained in the regions where both the Golgi canals and adjacent lipoidal bodies occur, namely, mainly in the zone basal to the zymogen granules. Thus it would appear that whereas the Golgi apparatus or lipoidal bodies may segregate vitamin C under certain conditions⁹, the vitamin does not constitute an essential or permanent part of either organelle. Similarly, it has been suggested that alkaline phosphatase might occur in the Golgi apparatus⁹. However, when Gomori's¹⁰ method was used on pancreas cells, I failed to detect alkaline phosphatase in the Golgi zone although a strong reaction was obtained in capillaries.

I am indebted to Dr. A. J. Marshall for his support in this work and would like to thank Prof. J. Rotblat,

Prof. C. Boswell, Dr. G. E. Francis, Miss M. Blundell and Miss M. Jeremy for help in various ways.

Solubility of Oxygen in Water

THE rate at which self-purification can occur in waters polluted by oxidizable organic matter may depend largely on the rate at which oxygen from the air is dissolved by the water. In natural water the rate of solution is influenced by many variable factors; but Adeney and Becker¹ have stated that for constant conditions, and for a uniformly mixed body of water, it is proportional to the difference between the concentration of oxygen in solution and the saturation or equilibrium concentration. Unfortunately, the absolute saturation values are not known with great precision; indeed, some of the values published by several independent investigators differ by as much as 0.4 part of oxygen per million at temperatures in the range 0°–35° C. The most generally accepted values are, however, those quoted by the American Public Health Association in "Standard Methods for Examination of Water and Sewage"²; these are based on gasometric determinations by O. J. J. Fox³.

In an investigation to provide information about the effect of natural variable factors on surface aeration, we have made many measurements of rates of aeration of pure water, the concentration of dissolved oxygen being determined by the Winkler⁴ titration method using an amperometric end-point⁵ in the final titration of iodine. We have consistently found that over a range of temperature 0°–35° C. the Adeney and Becker law of aeration is not satisfied when rates of solution of atmospheric oxygen are evaluated from the difference between the accepted saturation values and the dissolved oxygen concentration of the solution determined by the Winkler method. This discrepancy arises because the accepted saturation values are higher than the values obtained when the concentration of oxygen in water in equilibrium with atmospheric oxygen is determined by the Winkler method. This is a matter of some importance since it is the Winkler method which is most commonly used for the determination of dissolved oxygen and hence of rates of solution both in the laboratory and in field investigations.

In our experiments, the concentration of oxygen in deionized distilled water was either reduced or increased to a value well below or above the saturation value at a given temperature; the water was then slowly stirred to bring it into equilibrium with an atmosphere of air which had been saturated with water vapour and from which carbon dioxide had been removed. Measurements of dissolved oxygen were made at intervals until several successive samples, taken over a period of days, gave a constant value when corrected for changes in atmospheric

Fig. 1. Curve A, saturation values taken from "Standard Methods" calculated by Whipple and Whipple on measurements made by O. J. J. Fox (atmosphere assumed to contain 20.9 per cent oxygen); curve B, saturation values determined by the Winkler method.

pressure. This value was assumed to be the saturation concentration at the temperature of the experiment. The results obtained by this procedure are related by the empirical equation $C_s = 14.16 - 0.3943T + 0.007714T^2 - 0.0000646T^3$, where C_s equals saturation concentration in parts of oxygen per million and T equals temperature in degrees C. The standard error of the curve is 0.05 part of oxygen per million. A comparison between these values and those determined gasometrically by Fox are shown in Fig. 1. It is noteworthy that much better agreement with Adeney and Becker's law of aeration may be obtained with these saturation values than with the generally accepted ones. Moreover, for the purpose of determining rates of solution in natural waters, these saturation values are less 'artificial' than the accepted values in that they were obtained in waters in equilibrium with atmospheric oxygen rather than with pure oxygen in a sealed apparatus. It is of interest in this connexion that Holroyd and Parker⁶ in their work on the dynamics of aeration have reported that they were unable to approach the accepted saturation values, though they attributed this to a thermometric error.

The discrepancy between the saturation values we have obtained and the standard values has stimulated interest in the determination of absolute saturation values. A number of gasometric determinations of the saturation value of oxygen at 25° C. have been made in this laboratory, and the results so far obtained are in close agreement with the value calculated from the above equation at this temperature. These investigations are being continued, and a full account will be published elsewhere.

Volumetric Method for the Determination of Zirconium

KUMINS¹ observed that mandelic acid separates zirconium quantitatively from a large number of elements, and its use as a specific reagent for zirconium is being extended in analytical practice²⁻⁴, in preference to the time-honoured methods of affecting the separation as phosphate or basic selenite⁵. In a series of papers, Klingenberg and his colleagues^{6,7} have investigated the possibility of using α -hydroxy carboxylic acids as specific reagents for zirconium determinations and have shown that a direct weighing of *p*-chloro- and *p*-bromo-mandelates of zirconium is a satisfactory procedure for the gravimetric determination of the metal. The halo-derivatives of mandelic acid exert a large weighting effect on the zirconium ion and further, unlike the zirconium mandelate, these are not water-soluble. Hahn⁸ has further explored the use of *p*-bromo-mandelic acid for the determination of the zirconium-hafnium ratio by a computation from the combined weights of the *p*-bromo-mandelate of zirconium and hafnium and the weight of the oxides obtained therefrom by ignition. Jonckers⁹ has studied the reactivity of groups in relation to their application to inorganic analysis.

We have been engaged in a study of the cerimetric oxidation of organic acids and have found that mandelic acid can be quantitatively oxidized by ceric sulphate^{10,11}: the volume of ceric salt consumed can be used as a measure of the mandelic acid content. It was also noted that the same reaction can be extended to *p*-chloro- and *p*-bromo-mandelic acids.

In the present investigation we have explored the possibility of developing a volumetric method for the determination of zirconium by taking advantage of the above reaction.

Zirconium tetra *p*-chloro-mandelate was precipitated from a known volume of the zirconium solution by following the method of Klingenberg, filtered through a sintered-glass funnel of medium porosity, washed, dried and weighed. The halo-mandelate was dissolved from the crucible by a hot solution of ammonia, the solution acidified and boiled for fifteen minutes with a known excess of standard ceric sulphate solution. The excess was titrated back with standard ferrous sulphate solution using ferroin as internal indicator. The reaction may be represented as follows:

or 1 gm.mol. of zirconium tetra *p*-chloro-mandelate reacts with 8 gm.mol. of ceric sulphate. Similar reactions apply to the zirconium tetra-*p*-bromo-mandelate, and the same procedure was followed for precipitating, dissolving and titrating the zirconium salt.

In Table I are given typical figures obtained on 2 ml. each of a sulphuric acid solution of zirconium oxide.

It may be seen from the above that the cerimetric oxidation method is applicable to the volumetric determination of zirconium, and the results obtained are reproducible with a great degree of accuracy. The method is being extended to the determination of zirconium in ores and steels. It gives promise of application to even smaller quantities, and full details will be published elsewhere.

Table I

Method of determination	Wt. of zirconium oxide found (gm.)
(a) Gravimetric (phosphate method)	0.007633
(b) Gravimetric (from wt. of <i>p</i> -chloro-mandelate)	0.007590
(c) Volumetric (from vol. of ceric sulphate used for the chloro-mandelate)	0.007641
(d) Gravimetric (from wt. of the <i>p</i> -bromo-mandelate)	0.007592
(e) Volumetric (from vol. of ceric sulphate used for the bromo-mandelate)	0.007614

Our thanks are due to Dr. R. C. Shah, of the National Chemical Laboratory of India, Poona, who supplied the halo-mandelic acids, and to Sir K. S. Krishnan, director of the National Physical Laboratory of India, for his kind interest in the work and his permission to publish this communication.

Structure of Pristimerin

Bhatnagar and Divekar¹ described the isolation of an antibiotic, an orange-coloured pigment which they called 'pristimerin', from *Pristimeria indica* and *P. grahami* (Celastraceae). They found that this compound is particularly active against the *viridans* group of streptococci. We have been studying the constitution of this complex molecule.

Pristimerin crystallizes in orange needles of melting point 218–219° from petroleum ether–benzene. On the basis of analytical results and molecular weight (429) determined by X-rays (private communication from Prof. J. D. Bernal to Col. S. S. Bhatnagar), it has been assigned a molecular formula $\text{C}_{25}\text{H}_{32}\text{O}_4$. The physical and chemical properties and infra-red and ultra-violet spectroscopic evidence show it to be a β -quinone derivative. It contains one methoxy group and gives a negative Zerewitinoff test for active hydrogen. The latter observation finds confirmation in the infra-red absorption spectrum, in which the —OH band is absent. Reductively acetylated or methylated pristimerin (melting points 248° and 186° C. respectively) shows ultra-violet absorption suggestive of an acetoxyated or methoxyated benzene ring system, thus indicating that pristimerin may be a derivative of β -benzoquinone and not of naphthaquinone, nor of a quinone containing fused-ring systems of more than two aromatic rings.

Methylated pristimerin contains three methoxy groups and one double bond, and forms 2,4-dinitrophenylhydrazone, showing that the fourth oxygen in

the molecule is ketonic in nature. Lithium aluminium hydride reduces the orange solution of pristimerin in ether to a colourless solution which on acidification and aeration becomes orange in colour. Furthermore, two compounds (melting points 165°C . (dec.) and 205°C . (dec.)) without the methoxy group originally present in the molecule are obtained. The physical and chemical properties of these show that they still have β -quinone structure and are keto-enol isomers. Ultra-violet absorption curves of these compounds show that the third $-\text{CO}-$ group, which is reduced to $-\text{CHOH}-$ by lithium aluminium hydride, is probably conjugated with the β -quinone system. The fact that pristimerin does not form derivatives with ketonic reagents or orthophenylene diamine and gives a positive test with boracetic anhydride and tin tetrachloride suggests that the third keto group is sterically hindered and is probably in the peri-position to the β -quinone grouping. The labile character³ of the $-\text{OMe}$ group towards lithium aluminium hydride, acids or alkalis indicates its presence in the quinone part of the molecule, probably in a grouping $\text{OMe}-\text{C}=\text{C}=\text{O}$. Thus the chemical and physical data so far obtained can well be interpreted by the following tentative partial structure (I).

Preliminary selenium dehydrogenation experiments indicate that the molecule may be a steroid or triterpenoid. In view of this and of the fact that triterpenes have been isolated from this species of the plant, the partial structure (I) may possibly be further elaborated to (II).

(I)

(II)

Celastrol⁴, a quinone isolated from *Celastrus scandens* L., was assigned a molecular formula $\text{C}_{18}\text{H}_{16}\text{O}_4$. It appeared more than a coincidence that the melting points of pristimerin and the methyl ether of celastrol are the same. Ultra-violet absorption curves of pristimerin and celastrol are very similar, and both the compounds were isolated from the same family of the plant; hence a mixed melting point of pristimerin with methyl celastrol was taken. No depression was observed, showing that pristimerin and methyl celastrol are probably identical.

A complete account of this investigation will be published elsewhere. We are grateful to Col. S. S. Bhatnagar for suggesting this work and supplying pristimerin, to Prof. J. D. Bernal for determining molecular weight by the X-ray method, to Prof. O. Givold for sending a sample of methyl celastrol, and to Dr. V. M. Thakore for his collaboration in the initial stages of this work. We thank Dr. Bholanath for the preliminary experiments on selenium dehydrogenation.

Half-life of Curium-242

The most recently published value for the half-life of curium-242 is that of Hanna, Harvey and Moss¹, namely, 162.5 ± 2 days. This was determined by observing the proportions of americium-241 and curium-242 in samples of neutron-irradiated americium by pulse analysis methods over periods of up to one year.

The present measurements have been made by direct counting of α -particles from a source of pure curium which had been exhaustively purified from americium by ion-exchange methods. The α -counter used was of the low-geometry proportional type² designed for high precision and long-term stability³.

The curium source was deposited on a polished platinum disk. It was practically weightless, and gave initially about 2×10^7 α -disintegrations per minute. During a period of about seven months, fourteen measurements were made, each to a statistical accuracy of ± 0.1 per cent (that is, at least 10^4 counts were recorded).

It was necessary to correct for the growth of the long-lived α -active daughter, plutonium-238, and for this purpose the half-lives of curium-242 and plutonium-238 were taken as 162.5 days and 89 years respectively; but as these corrections amounted to less than one per cent of the counting-rate in every case, the final result is not critically dependent on these assumptions.

The corrected counting-rates were fitted by the least squares method to a linear relationship of the form:

$$\ln C_t = \ln C_0 - \lambda t,$$

where C_0 and C_t are the corrected counting-rates at time 0 and time t respectively, and λ is the decay constant of curium-242. The deviations of the experimental points from this straight line were quite random and showed no detectable trend with time, as would be expected if the sample contained any long-lived contaminant (for example, americium-241 of curium-243), or if the correction for plutonium-238 were inaccurate. The results were consistent with the existence of random effects producing a standard deviation of ± 0.1 per cent in addition to the standard deviation of ± 0.1 per cent due to counting statistics.

The slope of the least squares line gave a half-life value of 162.46 days with a standard deviation of ± 0.27 day.

¹ Hanna, G. O., Harvey, B. G., and Moss, X., *Phys. Rev.*, 78, 617 (1950).

² Hall, G. B., and Hurst, B., *Analyst*, 77, 970 (1952).

³ Glover, K. M., and Hall, G. B., *Nature* [173, 901 (1954)].

In connexion with the work described above, we have attempted to provide a check on the half-life of curium-242 by the entirely independent method of calorimetry.

A sample of approximately 2 μgm . of curium-242, slightly less pure than that used above, was kindly made available to us by Dr. J. Milsted. We have determined the total heat output of this sample at

intervals over a period of twelve months, using a specially designed twin microcalorimeter which gave a precision of measurement of approximately ± 1.5 microwatt (± 0.00086 cal./hr.). The small size of the sample and consequent very low heat outputs (400 μ W. at the beginning, falling to 100 μ W. at the end of the experimental period) seriously limit the precision attainable in the determination of the half-life; but the results appear to be sufficiently precise to confirm the value already published.

After correcting for the plutonium-238 daughter produced on decay, and for a small amount of a long-lived contaminant, we have computed the half-life from each pair of our results, using the formula:

$$\tau_{1/2} = \frac{0.693t}{2.303 (\log_{10} A_t - \log_{10} A_0)}$$

t being the time interval in days and A_t and A_0 the heat outputs corresponding to times t and zero respectively.

The mean value obtained is 163.0 days with a standard deviation of ± 1.8 days. A detailed account of this work is to be published elsewhere.

Speed of Circulation in Droplets

THE initiation of circulation in the form of vortex rings in droplets in motion in another liquid has been shown to depend on such physical properties as the viscosity of both the liquid in the droplet and of the outer liquid, and also particularly on the character of the interface. An attempt is now being made to obtain the velocity of circulation inside such liquid droplets in relation to their speed of fall or rise under varying conditions.

In preliminary experiments, droplets of redistilled nitrobenzene containing aluminium particles were allowed to fall through a 0.5 per cent w/w solution of 'Cellofas B' in tap water (viscosity c. 12 centipoises) contained in a square cross-sectioned column of dimensions 80 in. $\times$ 2 in. $\times$ 2 in. Their fall was photographed using a 16-mm. ciné camera to give a magnification of 1/3, and the camera table was counterbalanced by a weight and pulley system so

Fig. 1. The further the streaks from the centre of the droplet, the greater their elongation due to refractive distortion

Fig. 2

that with judicious hand pressure the path of the droplet could be followed. High-powered side-lighting was used, and the amount of aluminium in the dispersed phase was such that, with a camera speed of 64 frames per sec., dark streaks were recorded on the film by reflexion from the individual particles. A series of frames showing the fall of a droplet were enlarged by projection and, with each image of the droplet occupying the same position on the screen, successive streaks made by the same particle were plotted to trace the streamlines of circulation (Fig. 1).

From the length of the streaks and the frame-speed of the camera, the velocities along each streamline were obtained. After allowing for refraction at the interface by geometrical construction, these velocities were plotted against the distance from the centre of the droplet to the intersection of the streamline and the major axis.

The envelope of these points represents the velocity distribution in the vertical plane through the centre of the drop perpendicular to the optical axis, and its peak gives the highest circulation velocity. (Points below this envelope represent motion in other vertical planes, Fig. 2.)

For a droplet of major and minor axes equal to 0.59 cm. and 0.47 cm. respectively, this velocity was found to be 7.3 cm./sec. compared with a fall velocity of 13.4 cm./sec. For a spherical droplet the maximum possible circulation velocity is equal to 1.5 times the velocity of fall, so that it can be inferred that the circulation in this particular droplet is about 30 per cent of its maximum possible value.

The velocity of circulation decreased during fall; but as no attempt was made to eliminate injection effects due to the nozzle, it is not yet clear whether this was due to a change in the interfacial properties or not.

During the analysis there is a difficulty in accurately measuring the velocities, especially of particles at 'apparent' distances from the centre greater than half the radius. The work is being continued using liquids of the same refractive index in order to obtain the circulation velocity distribution more accurately, particularly nearer the surface of the droplet. It may then be possible to show how the relative rate of circulation varies with the physical properties of the system, and hence throw more light on the phenomena influencing the initiation of circulation.

Infra-Red Dichroism of Nylon and Polyethylene Terephthalate

In this laboratory we have been studying for some time the polarized infra-red spectra of single fibres and filaments. A 0.78 N.A. reflecting microscope of our own design, used with a Perkin-Elmer Model 12-C infra-red spectrometer in an arrangement similar to that of Blout, Bird and Grey¹, has allowed examination of specimens as narrow as 20 microns in width. Polarized radiation was obtained with a silver chloride sheet transmission polarizer. The very thin specimens required for the fundamental region of the spectrum were prepared by either longitudinally sectioning or mechanically flattening the single fibres.

A series of drawn specimens of nylon 66 and polyethylene terephthalate, kindly supplied by E. I. du Pont de Nemours and Co., Inc., have yielded results of particular interest. A summary of dichroism ratios observed for a number of absorption bands in specimens of different (nominal) draw ratio is given in Table 1. Each value represents the average of measurements made on 8-15 single filaments, and has been corrected for scattering losses, but not for the effect of beam convergence in the reflecting microscope. We have found that the latter correction is small, and does not alter the general results. It was also established that no appreciable double orientation was present in the specimens.

Table 1. DICHROISM RATIO ($\epsilon_{\parallel}/\epsilon_{\perp}$)

	cm. ⁻¹	Draw ratio					
		1	2.02	2.90	3.90	5.02	5.99
Nylon 66	3,810	0.98	1.85	1.25	0.98	0.79	0.84
	3,075	1.87	1.98	0.74	0.42	0.42	0.46
	2,930	0.92	1.23	1.20	0.96	0.90	0.99
	2,860	0.98	1.84	1.13	0.80	0.77	0.78
Polyethylene terephthalate	1,021	0.88	0.98	1.17	1.46	1.09	1.53
	975	0.43	1.61	2.04	3.43	3.92	8.03

It is seen that the four nylon absorption bands exhibit parallel dichroism at the lower draw ratios, and change over to perpendicular dichroism as the drawing proceeds. Hitherto, only perpendicular dichroism has been observed for these bands in highly oriented films^{1,2}. The 3,810 cm.⁻¹ N—H stretching vibration and the two methylene stretching motions at 2,930 and 2,860 cm.⁻¹ change dichroism in unison, as would be expected since the corresponding transition moments are all perpendicular to the chain axes. The 3,075 cm.⁻¹ band, the assignment of which is still in doubt, exhibits greater extremes in dichroism ratio, and changes from parallel to perpendicular character at an earlier stage. At draw ratios of 1 and 2 there is evidence that the extent of parallel dichroism for the 3,075 cm.⁻¹ band may be affected by the degree to which the filaments are flattened prior to infra-red examination⁴. This effect has not been observed for the other three bands of nylon 66.

We have observed that the change in dichroism character at about draw ratio 2.02 is quite general throughout the spectrum of polyethylene terephthalate. In addition to the 1,021 and 975 cm.⁻¹ bands, at least six other bands in the region 1,500-700 cm.⁻¹ reverse their initial dichroism as a result of drawing. The dichroism of the highly drawn filaments agrees in general with the results of Miller and Willis⁴.

In the nominally undrawn condition (draw ratio 1), dichroism was found to be present in the polyethylene terephthalate, and to a lesser extent in the nylon,

even though the undrawn filaments of both showed very low birefringence. The X-ray patterns of undrawn nylon indicated an unoriented, crystalline structure; on drawing, orientation was induced but with little change in crystallinity. The polyethylene terephthalate, initially amorphous, developed crystallinity on drawing, most markedly between draw ratios 2.99 and 3.99, where an inflexion in its birefringence curve appeared. In neither material, however, did X-ray patterns or birefringence measurements give evidence of a major reversal of chain orientation which the infra-red results alone might imply.

These results indicate that measurements of infra-red dichroism of fibres may reveal chain orientation which is not detected by the usual X-ray and optical techniques. Holmes *et al.*⁶ have reported that the amorphous regions in stretched polyethylene film are oriented at nearly right angles to the crystalline regions. It is possible that in poorly oriented fibre specimens the amorphous regions have a chain orientation quite different from that attained in the fully drawn, crystalline material, and that at the lower extensions the orientation of the amorphous regions largely determines the infra-red dichroism. Keller's recent suggestion⁷ of helical structures in synthetic polymers offers another very attractive explanation of some of these results, and is being investigated further.

Rotational Analysis of the Columbium Oxide Bands

In a previous communication¹, the rotational constants determined for the ground and excited states of the columbium oxide molecule have been reported as derived from the rotational analysis of the three bands λ 4,510 (1,0), λ 4,689 (0,0) and λ 4,915 (0,1). Due to an error, which has unfortunately crept in, in the calculation of the r_e values, it has since been found necessary to revise the analysis and to redetermine the constants. This work has been carried out. The two R and the two P branches and the K -numbering have been confirmed from the combination relationships. The revised rotational constants are:

$$\begin{array}{ll} B_0^* = 0.2447 \text{ cm.}^{-1} & B_1^* = 0.3776 \text{ cm.}^{-1} \\ B_2^* = 0.2420 & B_2^* = 0.3745 \\ B_3^* = 0.2451 & B_3^* = 0.3791 \\ \alpha^* = 0.0027 & \alpha^* = 0.0030 \\ I_0^* = 80.852 \times 10^{-40} \text{ gm. cm.}^2 & I_1^* = 73.814 \times 10^{-40} \text{ gm. cm.}^2 \\ r_0^* = 1.889 \text{ \AA.} & r_1^* = 1.805 \text{ \AA.} \end{array}$$

The D -values are of the order of 10^{-7} cm.⁻¹. Full details of this analysis will be published elsewhere.

Direct Measurement of Intensity Distributions in Star Images

MEASUREMENTS of the distribution of light intensity in the images of a star, formed by lenses, may be made with photomultiplier techniques. The experimental evidence so provided is of immediate application to the theory of the resolution of optical instruments, permitting confirmation of rigorous calculations, for example, those of Airy¹ for the aberration-free axial case; of Martin² for the axial case with aberration and of Hopkins³ for the general case at a position in the field of a system with aberrations. Another use for these measurements is in checking the accuracy of approximate methods of image calculation⁴. Apparatus based on photomultipliers has generally been designed to employ a slit probe, for facility of image location and in order to keep the incident flux at a convenient level. Results have been obtained by Ingelstam⁵, Schade⁶, Lindberg⁷ and Sprosen⁸ in this way, and R. E. Hopkins⁹ has used a circular aperture to measure the proportion of the total energy which falls within a chosen diameter of the image. The measurements made by these means need to be converted by the appropriate mathematical techniques in order to arrive at the requisite distributions. Direct intensity distribution measurements are evidently desirable provided the experimental difficulties of image location and low light level can be overcome.

An experimental arrangement has been developed for use with photographic lenses, having a 'point' probe which is small compared with the star image and which may be translated through sufficiently small distances to enable the image to be charted; facility is also provided for the location of the image. The photoelectric response of the multiplier has been found to be sufficient for this purpose, even at moderate dynode voltages, when using a condensed high-pressure mercury source. The experimental equipment is represented in Fig. 1 and comprises an artificial star, formed by the pinhole *S* and collimator *O*, a test lens *L* which forms an image of the star in the working plane of the microscope objective *O* and the photocell aperture *A* defining the region of the star image from which energy will be received. To the microscope is added a side-tube containing a monitor system; a thin (unsilvered) glass plate *M* and eyepiece *E*, which is set for line and made parafocal with the primary system by a subsidiary optical technique. The field of the eyepiece *E* is provided with a grid graticule so that co-ordinates of the position of the image of *A* in the working plane of *O* and also co-ordinates of the position of the star image are readily specified. Thus the star image is located. The image scan is accomplished by moving the object pinhole *S* through a small distance across axis, using the optical reduction of the collimator and test lens system to provide the very small image displacement required. The probe diameter is taken to be the reduced diameter of aperture *A* in the working plane,

Fig. 1. Experimental arrangement, comprising pinhole *S* illuminated by the source, collimator lens *O*, test lens *L*, microscope objective *O*, beam splitter *M*, receiving aperture *A* and eyepiece *E*.

Fig. 2. Intensity distribution in a star image. Cross-sections of the image are shown at several planes near focus. Intensity is shown vertically in arbitrary units.

and without difficulty this may be made less than $1/30$ of the diameter of the star image formed by a photographic lens of moderate or large focal length.

Preliminary work with this apparatus has given satisfactory results for a telephoto lens of 36 in. focal length and aperture $f/8.3$. Star images are commonly of the order of 0.0015 in. diameter in such cases; accordingly the probe diameter was made approximately 0.00005 in. by using an objective of 8 mm. focal length, the aperture *A* having a diameter of about 0.001 in. The object pinhole was moved through a distance of the order of 0.005 in. in the focal plane of a collimator of $3\frac{1}{4}$ times the focal length of the test lens. In Fig. 2 the image cross-sections are shown for a series of transverse planes in the neighbourhood of focus. Intensity is shown in arbitrary units vertically and lateral displacement is shown in intervals of 0.002 in. The traces are shown for planes displaced at equal intervals of 0.0185 in. along a third axis through the origin. These curves present a self-consistent model in agreement with standard results for a lens with appreciable under-corrected spherical aberration¹⁰ and which conforms with the general pattern of distributions calculated for other lenses of the same focal length⁴. In the plane of best instrumental focus, at 0.027 in. along axis from the origin, the central maximum has a half-width of 0.0018 in. and the first ring has a radius of 0.011 in., a comparatively large value. There is also a weak second ring at approximately twice the radius of the first ring. This ring structure cannot be detected visually in the general flare surrounding the image core, as the variations in intensity

are small, and the photoelectric technique seems preferable in such a case. Detailed developments in the apparatus are needed before trying to correlate experimental and theoretical results with the precision desired. At present the reproducibility of results is only 5 per cent, largely because of source fluctuations, the apparatus is inflexible and the taking of readings is tedious. The work, nevertheless, shows that a useful technique for direct intensity distribution measurements may be developed on this principle, and it is hoped that the specification of lens performance may be freed from the restrictions imposed by the present need to depend on photographic recording. A particular application lies in the determination of the significance of the width of the central part of the image.

Acknowledgment is due to the Chief Scientist, Ministry of Supply, for permission to publish this communication.

Oxygen Uptake and Carbon Dioxide Evolution of Heat-sterilized Soil

In a study of the respiration of soils at temperatures ranging from 10° to 70° C., it was found that oxygen uptake and carbon dioxide evolution increased with increasing temperature above 50° C.¹ The decline in plate counts at the higher temperatures indicated a gas exchange due to heat-stable enzymes or chemical oxidation and decarboxylation.

An investigation was then made on the gas exchange of soils subjected to various heat-sterilization treatments (Table 1).

These results show that the oxygen uptake increases with increasing severity of heat treatment. This suggests that the effect of heating is to expose oxidizable groups in the soil either by direct re-

Table 1. EFFECT OF HEAT TREATMENT ON GAS EXCHANGE OF SOIL.
(μ l./gm oven-dry soil/hr. at 30° C.)

CO ₂	17	3.0	1.8	2.5	2.9	0.7	1.7	1.9

duction or by the disruption of some fractions of the organic matter. The evolution of carbon dioxide from heated soils at 30° C. was low in comparison with oxygen uptake, but other work² has shown that the ratio of carbon dioxide to oxygen in autoclaved soils increases as the temperature at which respiration is being studied is increased.

The narrow carbon dioxide/oxygen ratio, the non-inhibition by microbial and respiratory inhibitors (Table 2) and the temporary nature of the gas exchange (Table 3) in the heat-sterilized soils are further evidence that the gas exchange is due to chemical oxidation.

Table 3. GAS EXCHANGE AT 30° C. OF AUTOCLAVED SOIL AT VARIOUS PERIODS AFTER HEATING
(μ l./gm./hr.)

	Time after autoclaving (15 lb./sq. in. for 1 hr.)			
	1 hr.	5 hr.	6.5 hr.	9 days
O ₂	25	18	12	0.8
CO ₂	8.6	4.3	3.0	0.6

The gas exchange of soil nine days after autoclaving is probably indicative of the chemical oxidation which occurs in soils at normal temperatures. This oxidation, while not significant in comparison with microbial respiration at normal temperatures, increases with increasing temperature. In exposed inland Australian soils, where temperatures of 47°–60° C. occur at one inch depth for several hours per day during summer months³, the chemical oxidation could be a significant factor in the decline in organic matter.

Rosette Disease of Groundnuts

ROSETTE disease of groundnuts annually causes great losses in many parts of Africa, and the degree of loss varies considerably. The disease is present in the three areas farmed by the Overseas Food Corporation in Tanganyika. At Kongwa in the Central Province losses are negligible, at Nachingwea in the Southern Province serious, while at Urambo in the Western Province they have been so great that groundnuts are no longer grown.

The vector of the disease is *Aphis craccivora* Koch. In natural bush the vector has been found on about twenty plant species, mostly Leguminosae, at

different times of the year. None of these has yet been proved to be a host of the virus¹. The principal variety of groundnut grown by the Corporation, Natal Common, is a short-season type, the seed of which is able to germinate when the plant is mature. Under suitable conditions of soil moisture volunteer plants from seed left in the ground at harvest provide host plants during the dry season for the vector and also the virus. Thus both vector and virus can survive until the early rains fall and new volunteers appear which soon become infected and are a source of virus for the new crop.

The negligible incidence of the disease at Kongwa is probably due to low rainfall, which usually has ceased by harvest time, so that soil conditions are not favourable for the germination of seed left in the ground. The few that do germinate usually die before the onset of the next rains. At Nachingwea and Urambo conditions are usually favourable for the germination of seed left in the ground and large numbers of volunteers appear, a high proportion of which survive through the dry season, carrying both the virus and its vector. Attempts at eradication of volunteers during the dry season by ploughing or hoeing have not proved satisfactory; on some soil types the soil is so hard that the blades do not penetrate sufficiently to give a good kill. Several operations would prove too costly.

Recent work at Nachingwea has revealed several promising lines of control. The systemic insecticide 'Schradan' used as a seed dressing has given complete control of aphids for the first three weeks in the life of the plant and also reduced the initial incidence of the disease, presumably by killing incoming infective winged aphids before they could infect several plants.

In a variety trial in 1951, Mwitunde appeared to show some resistance. In a similar trial in 1952 two strains of this variety showed considerably less disease than the other twenty-three varieties and gave the highest yields. A small area planted with these two strains for selection purposes showed only a few plants infected, while an adjacent area planted with other varieties was badly infected. Mwitunde seed was planted in a recently sown field of Natal Common. The resulting plants and some Natal Common plants were infested with infective aphids nine days after emergence. Two weeks later, the percentage of Mwitunde plants free from aphids, 34 per cent, was significantly higher than that for Natal Common, 14 per cent. The spread of infective aphids was measured by the number of Natal Common plants adjacent to the test plants that showed rosette. The spread from Natal Common was nearly six times higher than that from Mwitunde, the difference being highly significant.

The mechanism of this resistance has been investigated. Tests showed that when infested experimentally with infective aphids, Mwitunde was infected to the same extent as other varieties. Thus it appeared that its resistance was due to some difference in the behaviour of the vector on it. Field studies and laboratory tests showed that *A. craccivora* had no marked preference for other varieties over Mwitunde. In a series of experiments the rate of reproduction of the aphid on Mwitunde was highly significantly less than on Natal Common, being approximately only one-third. An explanation can now be offered for the higher percentage of uninfested plants of Mwitunde as compared with Natal Common. Coccinellid and syrphid predators, which are numerous

locally, were able to exterminate a higher percentage of colonies on Mwitunde because of their lower rate of increase. This resistance factor is only of value in areas where a suitably high predator population occurs, since although the rate of reproduction is comparatively low on Mwitunde, it is sufficiently rapid to cause loss of crop unless predators are present.

The more rapid extermination of colonies on Mwitunde only partly explains the lesser spread of disease on this variety. Tests of the percentages of aphids able to transmit rosette when reared on Mwitunde and Natal Common showed great variation in the degree of infectivity; but it was always lower on Mwitunde.

Percentage of infective aphids from		
Natal Common	Mwitunde	
31	0	P = 0.01
6	0	P = 0.05
51	32	P = 0.01
35	16	P = 0.01

The fourth experiment was designed to test differences in the infectivity of aphids from different plants as well as between varieties. There were highly significant differences between plants for both varieties, the range for Natal Common being 8-71 per cent, and for Mwitunde 0-32 per cent, suggesting that this resistance factor might be present to some degree even in such a uniform variety as Natal Common.

A third factor is being studied. In two instances where Mwitunde was so badly rosetted that ploughing in was considered, the yield proved to be 660 and 710 lb. of pods per acre compared with 1,040 lb. for a field much less severely rosetted. This suggests that the variety may have some tolerance to the virus.

Mwitunde possesses a further valuable characteristic, that of seed dormancy. The seed does not germinate until about ten weeks after the crop has reached maturity. By the time this dormant period has passed, the soil has dried considerably and only an occasional seed germinates. Thus there is an effective break in the carry-over of virus and vector from one crop to the next.

Mwitunde is a very mixed variety, showing great variation in size of plant, in habit, from prostrate to erect, and in pod and kernel characters. Thus the possibility of selecting a strain showing high yielding capacity together with a field resistance to rosette greater than that shown by the variety as at present constituted appears promising.

Life-history of *Porphyra*

In a recent publication¹, Kurogi reports the existence of a *Conchocelis*-phase in the life-history of four Japanese species of *Porphyra*. He confirms my observations on the germination of the spores liberated from thalli of *P. umbilicalis* v. *laciniata* as first reported in *Nature*² and described more fully in a recent publication³. Thus, the existence of a *Conchocelis*-phase in the life-history of species of *Porphyra* appears general. It also appears that the

Conchoecelis-phases of various species of *Porphyra* are very similar. As might be expected, the *Conchoecelis*-phase of *Bangia*⁴, a description of which is being prepared for publication, shows slight differences.

Fertile cell-rows develop on the *Conchoecelis*-phase in abundance and the next step in the elucidation of the life-history consists in showing how these spores are liberated and into what type of thallus they develop. Kurogi¹ shows they are liberated into the culture solution in great profusion², thus confirming my view and not that held by earlier investigators³ who supposed they were liberated laterally from each cell into the shell. Kurogi observed and figures the very early stages in the germination of these spores in all four species, *P. tenera* Kjellm., *P. suborbiculata* Kjellm., *P. umbilicalis* (L.) J.Ag. proz. and *P. pseudolinearis* Ueda. The method of germination of these spores is quite different from those which give rise to the *Conchoecelis*-phase and consists (excepting those of *P. umbilicalis*, proz.) of a very short row of quadrate cells. The cell contents are not indicated. Those of *P. umbilicalis* proz. show longitudinal division in the apical cell at a very early stage and they soon become obovate. None of the germings figured has more than fifteen cells, the majority fewer. Kurogi concludes that the spores liberated from the *Conchoecelis*-phase "germinated into such a bud of the leafy thallus of *Porphyra* as is found in the sea and they did not penetrate again into the shells".

If, in fact, these germings had been grown on and had developed into the leafy *Porphyra* thallus, it would appear that either the life-histories of different species of *Porphyra* may be variations of a basic type, or that the life-history of a given species may not always follow the same course. For one thing, the occurrence of 'plantlets' of considerable size and vigour, with every character of an independent phase, has been demonstrated already in the life-history of *P. umbilicalis* v. *laciniata*^{3,4}. Moreover, a further experiment I have carried out has demonstrated that sterile shells introduced into a

culture vessel containing shells 'infected' with the *Conchoecelis*-phase of this species themselves become 'infected' with the *Conchoecelis*. The first sterile shell to be introduced were in contact with the 'infected' ones; but subsequent sterile shells were suspended, by means of nylon thread, in such a way that they touched neither the vessel nor the 'infected' shells. Still they became 'infected' with *Conchoecelis*. In some cases the points of 'infection' were very numerous, as in the shell figured (Fig. 1). This shell was introduced into the culture vessel on February 27, 1953, and photographed on April 20, 1953. The culture used had been started in mid-November 1952. Similar experiments with the same results have been carried out with the *Conchoecelis*-phase of *Bangia fuscopurpurea* from Naples. It is clearly necessary to establish the method by which the spread of the *Conchoecelis*-phase from one shell to another has taken place, whether by vegetative filaments or spores, and if spores, whether there are two types of spores formed as appears possible on the basis of Kurogi's observations and those now reported.

It is certain that there is still much to be learned about the life-history of *Porphyra*.

A Rare Fungus in Surrey

On October 24, 1953, I was fortunate in collecting an example of the rare fungus *Batiarraea phalloides* (Dicks) Pers. The locality was Drud's Grove, Boxhill, and it was growing at the base of one of the large old yew trees which are a feature of that particular area. The specimen was rather small (9 cm. tall), as most records mention about one foot in height. Very few specimens have been recorded since it was first described by Thomas Woodward in 1784.

Dr. J. Ramsbottom, who deals extensively with this species in his recent book "Mushrooms and Toadstools", remarks that it is surprising that it is known with certainty elsewhere only from one locality in France and one, or perhaps two, in Italy. Incidentally, he also states that the last British record was from Temple Guiting, Gloucestershire, in 1915; but it now transpires that an example was found at the base of an elm trunk (in a hedgerow) at Callow Hill, near Virginia Water, Surrey, by Miss Notley on November 1, 1944, and is now at the Royal Holloway College.

My Boxhill specimen has been handed over to Mr. J. T. Palmer, who has kindly undertaken a revision of the British Gasteromycetes on behalf of the British Mycological Society.

Fig. 1. Sterile shell suspended in culture vessel containing shells 'infected' with the *Conchoecelis*-phase of *Porphyra umbilicalis* v. *laciniata* on February 27, 1953, and photographed April 20, 1953. Note the numerous areas of 'infection' by *Conchoecelis* now clearly visible. The dark linear areas in the fluting at the edge of the shell are mostly due to diatoms. Nat. size

FORTHCOMING EVENTS

(Meeting marked with an asterisk * is open to the public)

Monday, June 28—Friday, July 2

ROYAL INSTITUTE OF CHEMISTRY (at the University, St. Andrews)—Symposium on "Recent Advances in the Chemistry and Industrial Applications of Cellulose".

Wednesday, June 30

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 4.45 p.m.—Dr. Alfredo Massimo: "The Steam Vents of Tuscany". Exhibits relating to the Pliocene problem by Mr. A. T. Marston; Prof. W. M. Le Gros Clark, F.R.S., and Dr. J. S. Weiner; Mr. S. H. V. Bowie and Dr. O. H. Davidson; Dr. G. F. Clarnbull and Dr. M. H. Hey; Dr. K. P. Oakley.

INSTITUTE OF METALS (at 4 Grosvenor Gardens, London, S.W.1), at 5 p.m.—Prof. H. Orowan, F.R.S.: "The Brittle Fracture of Metals: Some New Developments".

Thursday, July 1

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. H. B. Scott (McMaster University): "The Influence of Aerial Methods on the Evolution of Geological Reconnaissance".

INSTITUTE OF PHYSICS, LONDON AND HOME COUNTIES BRANCH (at the Royal Institution, Albemarle Street, London, W.1), at 6 p.m.—Dr. Karl Darrow: "Some Current Work at Bell Telephone Laboratories".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (with veterinary qualifications) in ANIMAL PHYSIOLOGY AND ANIMAL HEALTH in the Department of Agriculture (Animal Husbandry)—The Registrar, University College of Wales, Aberystwyth (June 30).

UNIVERSITY DEMONSTRATOR IN PHYSICAL ANTHROPOLOGY at the University of Cambridge—The Secretary of the Appointments Committee, Faculty of Archaeology and Anthropology, Downing Street, Cambridge (June 30).

SCIENTISTS (with a good honours degree or equivalent, in engineering or physics, and with relevant postgraduate experience in any of the following fields: light engineering development, pneumatic and/or hydraulic mechanism design, design of light electromechanical mechanisms, optical mechanisms), at the National Coal Board Central Research Establishment II, Isleworth, Middlesex, to undertake fundamental research into the underground problems arising in the mining of coal—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/791 (July 1).

ASSISTANT LECTURER IN BACTERIOLOGY—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (July 3).

ASSISTANT LECTURER (qualified to teach the history of modern philosophy) of PHILOSOPHY—The Registrar, University College of North Staffordshire, Keele, Staffs. (July 3).

ASSISTANT (with a recognized qualification in microbiology or training or experience in microbiological methods) in MICROBIOLOGY at Long Ashton Research Station—The Secretary, Research Station, Long Ashton, Bristol (July 3).

EXPERIMENTAL OFFICERS or ASSISTANT EXPERIMENTAL OFFICERS (with H.S.C. (science) or equivalent; a pass degree in mathematics or experience in computing, aerodynamics, statistics, etc., an advantage), at Ministry of Supply Experimental Establishments in or near London, for computational work connected with performance of armaments and aircraft, supervision of a small group of assistants and some responsibility for the development of new computing techniques—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.164/54A (July 3).

LECTURER IN ENGINEERING—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (July 3).

RESEARCH ASSISTANT IN THE DEPARTMENT OF PURE MATHEMATICS—The Registrar, The University, Liverpool (July 3).

RESEARCH DEMONSTRATOR IN ZOOLOGY—The Registrar, The University, Sheffield (July 3).

SENIOR TECHNICIAN IN THE DEPARTMENT OF PHYSICS, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (July 3).

LECTURER, Grade A (with a good honours degree) in PHYSICS at Kuman College (Gold Coast College of Technology, Science and Arts)—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (July 4).

LECTURER (with a degree or a recognized diploma in mining) in THE DEPARTMENT OF MINING AND GEOLOGY—The Principal, Wigan and District Mining and Technical College, Wigan (July 6).

PRINCIPAL OF SOUTHEAST TECHNICAL COLLEGE, Southall, Middlesex—Chief Education Officer (F/CW/2), Middlesex County Council, 10 Great George Street, London, S.W.1 (July 6).

ASSISTANT LECTURER IN GEOGRAPHY—The Registrar, The University, Sheffield (July 7).

CHAIR OF CHEMISTRY at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (July 10).

LECTURER and an ASSISTANT LECTURER in THE DEPARTMENT OF GEOGRAPHY—The Registrar, The University, Manchester 13 (July 10).

ASSISTANT LECTURER IN CHEMISTRY—The Registrar, Wye College, near Ashford, Kent (July 12).

SCIENTIFIC OFFICER (with a good honours degree in botany or agricultural botany, and an interest in fruit culture) in THE DEPARTMENT OF POMOLOGY, for research into the growth and development of soft fruit plants, principally the raspberry, and an EXPERIMENTAL OFFICER in THE VEGETABLE CULTURES SECTION, to assist with a plant breeding programme for varieties suited to Scottish conditions—The Secretary, Scottish Horticultural Research Institute, Mylnfield, Invergowrie, by Dundee (July 15).

LECTURER or RESEARCH ASSISTANT IN BACTERIOLOGY AND VIRUS DISEASES—The Registrar, The University, Sheffield (July 17).

RESEARCH FELLOW IN PURE MATHEMATICS—The Registrar, The University, Edgbaston, Birmingham (July 17).

SENIOR LECTURER (preferably qualified and willing to develop research in geochemistry) in GEOLOGY at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, July 19).

CHAIR OF EDUCATION at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, July 30).

PROFESSOR OF GEOPHYSICS—The Director, Institute of Astronomy, Helwan, Egypt (July 31).

PROFESSOR OF PHYSICS at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (New Zealand, July 31).

ASSISTANT HISTOLOGIST (Senior Scientific or Scientific Officer grade) in THE BEE RESEARCH DEPARTMENT, for work on bee breeding and the pollination of crops—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

CHEMIST (with a degree in natural science, and preferably with postgraduate experience, particularly in soil survey work) in THE AGRICULTURAL DEPARTMENT, Sierra Leone, to make a soil survey of part of the Northern Province of Sierra Leone, with particular reference to the nutrient status and fertilizer requirements of soils suitable for mechanized rice cultivation—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.63/15/04.

CHEMIST (with an honours degree and preferably with some knowledge of food analysis) for research and analytical work in connection with the study of problems of fruit and vegetable preservation—The Director, Fruit and Vegetable Canning and Quick Freezing Research Association, Research Station, Chipping Campden, Glos.

DEMONSTRATOR IN PHYSICS—The Registrar, The University, Nottingham.

ENGINEERS, SCIENTISTS and ARCHITECTS (with an aptitude for committee work), to act as Secretaries to Committees dealing with a variety of subjects—The Establishment Officer, British Standards Institution, 2 Park Street, London, W.1.

EXPERIMENTAL OFFICERS (with at least H.S.C. (science) or equivalent, and preferably with a pass degree in chemical engineering or applied chemistry), or ASSISTANT EXPERIMENTAL OFFICERS (with at least H.S.C. (science) or equivalent), to assist in chemical engineering investigations and development work—The Administrative Officer (Recruitment), Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 74/W.G.B./84.

LECTURER IN EDUCATION at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1.

LIVESTOCK RESEARCH OFFICER (with a good honours degree in agriculture or equivalent, and at least four years postgraduate experience in field experimentation and tropical agriculture, with particular reference to pasture management and animal husbandry), at Ebin Livestock Experimental Station, British Guiana, for duties which will include the planning and supervision of research and other projects for the purpose of ascertaining the most economic methods of developing the minerally-derivative savannahs of the area—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BOD 87/80/01.

MATHEMATICIANS, SCIENTIFIC OFFICERS, ASSISTANT EXPERIMENTAL OFFICERS or EXPERIMENTAL OFFICER grades, at Ministry of Supply Research and Development Establishments, mainly in Southern England, for work in problems chiefly concerned with aircraft, radio and radar equipment and armaments—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.141/54A.

RESEARCH ASSISTANTS (with a good honours degree in physics, and preferably with previous experience in solid state physics) in THE PHYSICS DEPARTMENT—The Professor of Physics, University of Reading, Physics Research Laboratories, 78 Upper Redlands Road, Reading, Berks.

SCIENTIFIC OFFICERS, CHEMISTS and CHEMICAL ENGINEERS (with a first- or second-class honours degree in chemistry, physics or chemical engineering or equivalent qualification, and preferably with experience in one of the following: (a) Infra-red spectroscopy in the field of organic chemistry; (b) development of new methods and application of physico-chemical techniques in an analytical laboratory with an organic bias; (c) organic chemistry, particularly with the synthesis of fluoro derivatives or organic compounds; (d) development of laboratory methods of organic synthesis to pilot plant scale), at the Atomic Weapons Research Establishment, Aldermaston, Berkshire—The Administrative Officer (Recruitment), A.W.R.E., Aldermaston, Berks, quoting 112/W.G.B./2.

SENIOR SCIENTIFIC OFFICER or SCIENTIFIC OFFICER (with a first- or second-class honours degree in mathematics or physics, or equivalent qualifications, and for the senior post at least three years postgraduate research experience), to work on theoretical problems with meteorological applications—The Administrative Officer (Recruitment), Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 149/W.G.B./34.

TECHNICAL LIBRARIAN AND INFORMATION OFFICER (Chartered Librarian with considerable experience in industrial libraries, and preferably with a technical or scientific qualification), to establish and develop an information department and library in an important industrial organization in the Midlands—The Director, Ashby, 4 Palace Gate, London, W.8.

TECHNICIAN (BIOCHEMICAL) (preferably with experience in organic chemistry), for research and some routine work on steroids—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W 2

TOBACCO RESEARCH OFFICER (with a good honours degree in botany, agricultural botany or agriculture, and at least two years postgraduate training and experience in field experimentation and crop husbandry generally) in the Department of Agriculture, Nyasaland, to carry out experimental work on tobacco growing and curing, under the general direction of a tobacco expert—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODR.63/4/04

B.T.L. INSTRUMENT INFORMATION

THE B.T.L. HUMIDITY CONDITIONING OVEN (MARK II)

The B.T.L. Humidity Conditioning Oven is constructed of welded angle iron which forms the framework for the copper sheet casing and solacite panels of the outer casing. The outer door is suitably lagged and the glass inner door is sealed with rubber beading. The oven is fitted with runners to accommodate removable shelves for test samples. Trays for drying agents or water may be placed on the floor of the oven. The door is drawn over the trays and distributed evenly round the oven by a centrifugal fan running at 3000 r.p.m. Adjustable air dampers are fitted in the top and one side for operations requiring a change of air. Temperature control is effected by a four position switch working in conjunction with a bimetallic regulator.

A dew-point thimble fitted to the outside, a wet and dry bulb hygrometer fitted to the inside can be provided as an accessory for the measurement of humidity.

Maximum relative humidity using water 9% (approx) at 85°—90° C.; using normal drying agents 2% (approx) at 90°C. 10% (approx) at 25°C. Minimum working temperature is ambient + 6°C. Voltage ranges 200/220v and 230/250v A.C. only.
